

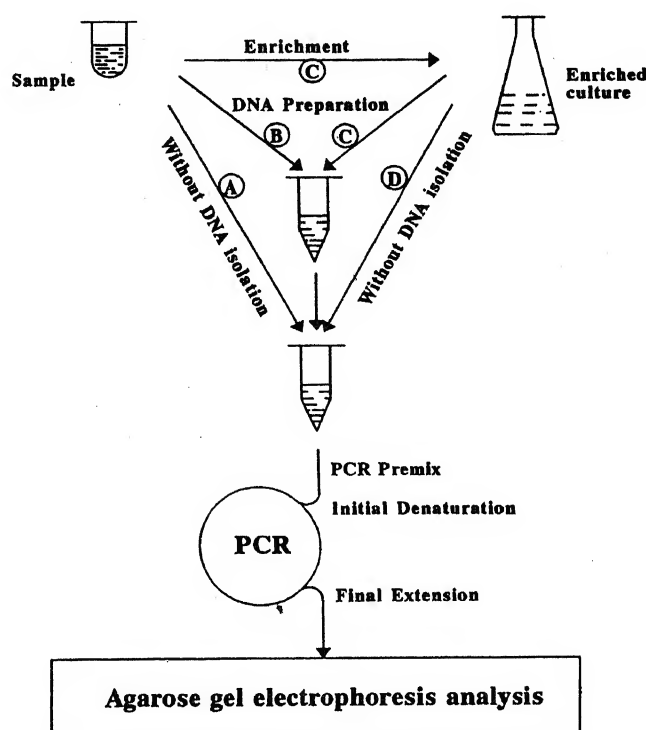

Figure 3. Flowchart for PCR-based detection of *L. monocytogenes* during path: A, without enrichment and without DNA isolation; B, without enrichment and with DNA isolation; C, with enrichment and with DNA isolation and D, with enrichment and without DNA isolation.

specific pair of primers (Table 2) is applied to either (i) DNA isolated with or without enrichment, or (ii) directly to sample or enriched broth to amplify DNA sequences present in *L. monocytogenes* only. The amplified products are resolved on an agarose gel and presence of a specific band signals the sample to be *L. monocytogenes* contaminated. Both positive (isolated template DNA) (PC) and negative controls (NC) (reagents without template DNA) are included to ascertain success of PCR and detect contamination of exogenous DNA respectively.

Reagents

A complete kit as well as individual reagents are available with commercial suppliers and should be used in accordance with manufacturers' instructions. Oligonucleotide primers are specific to each assay employed and can be synthesized in the laboratory or from custom oligonucleotide synthesis facility of commercial suppliers. All components may be premixed, aliquoted and stored in a separate section of the freezer dedicated for PCR reagents located near a laminar flow hood.

Table 2. Primer pairs used in *L. monocytogenes* detection assay

Target gene	Nucleotide sequence from 5' to 3'	Amplified product (bp)	Reference

Primers. Success of detection assay basically depends upon the sequence of primers. The mistakes here will either result in no amplification or non-specific amplification. Availability of nucleotide sequence of target fragment is a must. There are no set rules, but oligonucleotide primers are generally in the range of 18–30 bases in reverse orientation to each other, have similar GC content (>50%), similar T_m , minimal secondary structure (i.e. self-complementarity) particularly in the 3' region (to reduce primer dimer formation), low complementarity to each other, and are specific to target DNA with no cross hybridization to non-target DNA sequences from the same or related species⁴⁷. These are generally designed with the help of a computer program and a number of such programs are available from commercial software suppliers⁴⁸. Some of the primer pairs used in detection assay are given in Table 2.

The optimal concentration of primers to be used in the reaction mixture ranges between 0.1 and 0.5 μ M. Higher primer concentration should be avoided as this may promote mispriming, resulting in nonspecific amplification. Annealing temperatures should be 5–10°C below T_m . However, annealing at higher temperatures for slightly extended times, especially in first few cycles reduces mispriming and helps in increasing the speci-

ficity of the primer pair used in the detection assay. Hot start reduces primer dimer formation⁴⁹.

PCR buffer. Composition of PCR buffer particularly the concentration of Mg^{++} has profound effects on the specificity and yield of amplification. Apparently low Mg^{++} may result due to the presence of EDTA or other chelators in primer or template DNA stocks. Excess of Mg^{++} may result in accumulation of nonspecific products. Therefore, titration of Mg^{++} is highly desirable. Nowadays, PCR buffer without $MgCl_2$ along with a stock solution of $MgCl_2$ is supplied for this purpose (Boehringer Mannheim). Inclusion of Triton-X-100 and/or gelatin has stabilizing effect on enzymes used in PCR and result in better yield. Some recent protocols have recommended the use of 10% DMSO to reduce secondary structures of target DNA.

Deoxynucleotide triphosphates. The dNTPs bind Mg^{++} quantitatively, therefore, dNTPs' concentration in a reaction mixture will determine free Mg^{++} available for enzyme activity. dNTPs are used at 200 μ M final concentration and approximately 50% of dNTPs are left unused after PCR amplification cycles. The pH of the dNTPs stock solution should be neutral. A number of biotechnology companies have come up with stock solution of 100 mM ready-to-use solutions.

Table 3. PCR protocols for detection of *L. monocytogenes* in dairy foods

Sample preparation	Dairy food	Sensitivity	Target gene with amplified product (bp)	PCR parameters	Reference
Direct detection	Inoculated milk	10 bacteria/10 ml	<i>hly A</i> 234 bp, <i>iap</i> 131 bp	D = 30", 95°C; A = 1', 55°; E = 1', 72°C; FE = 5', 72°C; C = 40	62
Direct DNA extraction	Inoculated soft cheeses	10 ³ –10 ⁸ cfu/0.5 g	<i>Dth</i> 112 bp, <i>dth</i> 326 bp	ID = 3', 94°C; D = 1', 94°C; A = 2', 54°C; E = 3', 72°C; C = 30	53
18 h enrichment before DNA extraction	Inoculated yoghurt, skim milk, mature cheese, soft cheese cream	10–100 cfu/g food inoculated with 10 ⁴ cfu/g	<i>hly A</i> 417 bp	ID = 7', 94°C; D = 1', 15", 95°C; A = 30", 62°C; E = 30", 72°C; FE = 1', 72°C; C = 30	51
Overnight enrichment before DNA extraction	–	5–50 cells	<i>hly A</i> 175 bp	ID = 4', 95°C; D = 45", 95°C; A = 45", 60°C; E = 1', 72°C; FE = 5', 72°C, two rounds of 35 cycles	44
Overnight enrichment before DNA extraction	Inoculated pasteurized 2% milk	0.1 cfu/ml of milk	<i>hly A</i> 240 bp, <i>hly A</i> 267 bp; <i>hly A</i> 299 bp; <i>hly A</i> 520 bp; <i>hly A</i> 560 bp	D = 1', 94°C; A = 1', 55°C; E = 2', 72°C; FE = 5', 72°C; C = 36	50
48 h enrichment before DNA extraction	Milk, ice-cream	10 cfu/25 g food before enrichment and 100 cfu/ml of enrichment broth	<i>hly A</i> 388 bp	D = 5', 94°C; D = 1', 94°C; A = 1', 65°C; F = 2', 70°C; C = 30	64

ID = Initial denaturation; D = Denaturation; A = Annealing; E = Extension; FE = Final extension; C = Cycles.

Enzymes. Thermostable DNA polymerase is the enzyme required for amplification and is available with a number of manufacturers. Taq DNA polymerase, the commonly used enzyme in PCR, has been isolated from *Thermus aquaticus*, which has 5' to 3' polymerase activity.

Template DNA. Template DNA used in PCR varies from pure genomic DNA to crude preparation of cells as in dairy foods. Whatever the method employed, the sample should always be taken in either pure sterile triple glass distilled water or 1X PCR buffer.

Protocols

PCR is carried out for amplification of *L. monocytogenes* specific DNA fragment according to the standard procedure as described by Saiki *et al.*³⁹ with modifications to favour optimum amplifications (Table 3). A sensitive and specific method for detection of *L. monocytogenes* in dairy foods consists of culturing samples in listeria enrichment broth (LEB) and subculturing them from LEB to listeria plating media, followed by DNA extraction and species-specific detection of the organism using the PCR⁵⁰. A short enrichment period before PCR amplification allowed detection of the organisms in a range of complex foods contaminated with 104 c.f.u./g, within 24 h or 2 d in soft cheese⁵¹. A novel method employing PCR-coupled ligase chain reaction (LCR) has also been developed for specific detection of *L. monocytogenes*⁵².

The natural samples of dairy foods contain components that inhibit the action of the polymerase enzyme

and necessitate either their specific removal or DNA purification. A considerable decrease of PCR inhibition was obtained by phenol extraction, but, it simultaneously reduced the total amount of DNA which is available for amplification. However, Qiagen columns (prepacked with an ion exchange resin) specifically bind DNA and release this DNA upon elution with a buffer of high ionic strength. Purification of cheese extracts on these columns, in contrast to phenolization, did not lead to excessive loss of DNA in the final preparation⁵³. The direct detection, using PCR of *L. monocytogenes* added to cow milk was also inhibited at some milk concentrations. This inhibitor was moderately heat stable. Inhibition could be prevented by the addition of bovine serum albumin or proteinase inhibitors to the PCR and the evidence suggests that the inhibitor was plasmin⁵⁴.

The polymerase chain reaction detection method, in which the enrichment culture was directly tested, rendered false negative results for 3 soft cheese samples due to the presence of components in the enrichment culture of this cheese that inhibit the PCR⁴⁰. A new detection system – magnetic immuno polymerase chain reaction assay (MIPA) – separates listeria cells from PCR inhibitory factors present in enrichment broths containing food samples by using magnetic beads coated with specific monoclonal antibodies (MAbs)⁵⁵. But in a sensitivity test, PCR was strongly inhibited by cheese components and not by the ingredients of the enrichment broth. Use of DNA purification matrices (DNA Capture Reagent and Geneclean II) may increase the detection limit approximately hundredfold⁵⁶. DNA extracted

REVIEW ARTICLE

directly from mozzarella cheese artificially contaminated with *L. monocytogenes* samples was amplified by PCR. Amplification was obtained for all samples even at a concentration of 3 cells/g cheese and no interference from natural microflora cheese was observed⁵⁷.

PCR detects both viable and dead *L. monocytogenes*. Therefore, during initial screening with PCR, samples detected positive for *L. monocytogenes* must be tested subsequently using culture methods to confirm for viability of *L. monocytogenes*. Alternatively, PCR protocol may be modified to detect mRNA which represents active and viable cells. Since an oral dose of 10⁵ virulent *L. monocytogenes* is required to cross the intestinal barrier in healthy immunocompetent humans, for a PCR based method to be completely successful, quantitation may also be undertaken in addition to qualitative detection. Perhaps in future, the development of kinetic PCR⁵⁸ and its application to real-time monitoring of DNA amplification reaction run against a concentration standard may provide solution to quantitation problems using PCR.

Analysis of amplified products

The amplified products are resolved on 2–3% agarose gel. The ethidium bromide stain is included in the gel for it increases the clarity of the results as compared to staining the gel after run. The gel is run at constant volts (5–10 V/cm) for 30–70 minutes in 1X TAE buffer and visualized under UV lights. Although the basic setup is same in all cases, the length of amplified fragment is different for each pair of primers. If an expected pattern for PC and NC is obtained, then the assay is valid and there is no contamination. Results can be interpreted accurately. If NC shows PC pattern (due to contamination), then no interpretation is possible.

Avoiding false positives

Since the PCR is a powerful technique to detect even a single copy of target DNA, a false positive may occur if exogenous DNA finds its way to PCR tube. PCR amplifies the target fragment to a large copy number and each fragment is capable of serving as template for the next PCR. Therefore, even if a single copy of amplified product finds its way to the next PCR tube, the detection assay will give a wrong signal. This is called carry over contamination to distinguish it from contamination from naturally-arising DNA. Separate working areas should be allocated to pre-PCR, PCR and post-PCR work. Use of positive displacement pipettes is recommended to avoid pipette barrel contamination. Also, separate sets of pipettes should be allocated for PCR and post-PCR

works. The pipette set used for PCR work should be labelled with red tape and in no circumstances should be used for post-PCR work. Disposable gloves are advised at all the times during PCR set up and frequent change of gloves. All the tubes are closed to avoid air-borne contamination. Given below are the tips which should be kept in mind while performing *L. monocytogenes* detection using PCR^{59–61}.

Pre-PCR work. Prepare reagents in a separate area, premix to 2X stock solutions, aliquot and store these in a freezer section dedicated to store PCR reagents. Record the number of each lot so that if contamination is suspected, it can be traced out easily. Use dedicated chemicals for PCR including water. Autoclave PCR tubes, tips, triple distilled water and mineral oil. Use screw-capped tubes for stocks or tubes that do not require much force to open. This is to avoid splashes and associated contamination. Use siliconized tubes.

PCR-work. Assemble PCR in a clean laminar flow hood having UV lamp. Switch the UV lamp on when the hood is not in use. Expose PCR premix for 5 minutes under UV (254 nm) before assembling PCR in case contamination is suspected. This destroys the template DNA through cross linking whereas primers are safe. Set up positive controls at the beginning and negative control at the end. This represents that the same premix is being added to all tubes and reflects that there was no contamination of premix during reaction set up.

Post-PCR work. This is the area where carry over contamination can arise and maximum care should be taken to prevent spread of carry over contamination. Amplified product containing tubes, gels, tips used for gel loading should be sealed in plastic bags along with a little bleach and disposed off safely. Under no circumstances should these disposables find their way to the pre-PCR area or the PCR area. To prevent 'carry over' contamination from equipment used in post-PCR area, gel apparatus should be soaked in 1 M HCl to depurinate any residual DNA. Surface of the UV transilluminator should be covered with a fresh sheet of plastic wrap for each gel.

Conclusion

Consumption of dairy foods has been recognized as an important transmission route for human listeriosis causing health hazards among public. This demands a successful detection assay to declare dairy foods free of *L. monocytogenes*, the causative pathogen. Various approaches have been used to detect *L. monocytogenes*. PCR offers a successful assay for detection of *L. monocytogenes* in dairy foods. A single copy of specific target DNA is sufficient, enhancing its sensitivity. The assay is rapid enough to provide results on the same day. In addition, it is simple, reliable and accurate. Also, per-

sons without formal education in molecular biology can perform the assay after training. Although the assay is quite easy to perform, it is vulnerable to carry over contamination giving ambiguous results. Therefore, we caution against the spread of contamination. As the methods to distinguish between genuine sample and contamination-related amplification become available, detection assay will be feasible on a single bench without the fear of contamination. In addition, there is need to modify PCR protocols to target mRNA for active and viable *L. monocytogenes* detection sparing dead ones. Also, efforts should be directed towards evolving a quantitative assay.

RESEARCH ARTICLE

Comparative sequence analysis and expression in *E. coli* of the subgroup I-specific antigen VP6 from a G2 serotype human rotavirus IS2

Saima Aijaz* and C. Durga Rao*[†]

*Department of Microbiology and Cell Biology, [†]Centre for Genetic Engineering, Indian Institute of Science, Bangalore 560 012, India

VP6, the intermediate capsid protein of the virion, specifies subgroup specificity of rotavirus. It is also the most conserved, both at nucleotide and amino acid levels, among group A rotaviruses and is the target of choice for rotavirus detection. In this study we report the sequence of the subgroup I (SGI)-specific VP6 from the serotype G2 strain IS2 isolated from a child suffering from acute diarrhoea in Bangalore and its comparison with the published VP6 sequences. Interestingly, IS2 gene 6 shared highest homology with that from bovine UK strain and the protein contained substitutions by ly-

sine at amino acid positions 97 and 134. In contrast, the amino acids Met and Glu/Asp at these respective positions are highly conserved in all the other group A rotaviruses sequenced so far. These observations have obvious implications for the evolution of serotype G2 and G2-like strains circulating in India. The SGI VP6, of a human rotavirus, possessing epitopes that are conformationally similar to those found in the native protein in the virion, was successfully expressed in *E. coli* and purified for the first time by single-step affinity chromatography.

DIARRHOEAL diseases are the major cause of morbidity and mortality among infants and young children, especially in developing countries. Of the many diarrhoeal agents, rotavirus is the single most important cause of severe, acute infantile gastroenteritis in humans and a variety of domestic animals¹. Rotavirus diarrhoea occurs throughout the year and is estimated to account for about a million deaths annually among young children, thus representing an important public health problem^{1,2}.

In spite of the staggering economic burden, an effective vaccine against rotavirus diarrhoea is yet to be developed.

Rotavirus belongs to the family Reoviridae and consists of a triple-layered capsid³. The outer shell consists of two proteins, VP4 and VP7, the intermediate shell comprises of VP6 and the inner shell is composed of VP2 that encloses a genome of 11 segments of double-stranded (ds) RNA^{3,4}. The genome encodes 6 structural

and at least 5 nonstructural proteins⁵. The outer capsid proteins VP7 and VP4 specify two independent serotype specificities, the G and P types respectively⁶. VP6, encoded by gene segment 6, contains group as well as subgroup-specific epitopes^{6,7}. On the basis of group-specific epitopes, 7 groups A to G have been identified in humans and animals⁵. Group A rotaviruses, the most common pathogens in humans, can be further subdivided into at least 4 subgroups SGI, SGII, SGI + II and non SGI/II on the basis of the SG-specific epitopes⁸. Group A rotaviruses can also be initially characterized as 'short' or 'long' electropherotypes depending on the slower or faster electrophoretic migration, respectively of the dsRNA segment 11 in polyacrylamide gels¹. In general, majority of the human rotaviruses with SGI specificity belong to G2 serotype and exhibit 'short' RNA electropherotype whereas those with SGII specificity have 'long' RNA pattern and belong to other serotypes¹. In contrast, the great majority of animal strains appear to possess 'long' RNA pattern but SGI specificity^{1,9}.

VP6 comprising more than 50% of the virion mass is an important viral antigen and is involved in several viral functions such as replication, transcription and viral morphogenesis^{5,8,10,11}. Although majority of the serum antibodies in the infected host are directed against VP6, anti-VP6 IgG antibodies have not been conclusively shown to be capable of virus neutralization⁸. Recent studies, however, indicate that mucosal anti-VP6 secretory IgA antibodies play an important role in protection against the rotavirus disease¹². VP6 also contains epitopes recognized by cytotoxic T-lymphocytes as well as helper T cells, indicating a role for VP6 in stimulating heterotypic cell-mediated immune response¹³⁻¹⁵. VP6 was shown to function as an excellent immunological carrier for peptides and proteins in vaccine development¹⁶. Because of its high abundance, stability and high degree of conservation among human and animal group A rotaviruses, majority of the procedures for detection of rotaviruses in clinical samples are based on VP6 (refs 7, 17, 18).

Although the SGI-VP6 from a few animal strains had been expressed¹⁹⁻¹², that from a human rotavirus has not been reported. Because of the importance of VP6 in viral diagnosis and to determine the sequence variation in VP6 from Indian rotaviruses, we report here the cloning, comparative sequence analysis and expression in *E. coli* of the SGI VP6 from an Indian G2 serotype strain IS2 isolated from a child with diarrhoea in Bangalore.

Materials and methods

Extraction of viral genomic dsRNA and purification of the RNA segments

Isolation and serotypic characterization of rotaviruses including the G2 serotype strain IS2 isolated from chil-

dren suffering from diarrhoea admitted to various hospitals in Bangalore has been described earlier¹⁸. As IS2 was not adapted to growth in culture, nucleic acids were extracted directly from the clarified supernatants of the 20% suspension of the stool sample as previously described¹⁸. The dsRNA was electrophoresed on a 1% agarose gel in presence of ethidium bromide and the RNA segments 5, 6, 7, 8 and 9 were electroeluted together onto a dialysis membrane and purified by phenol-chloroform extraction²². For identification of gene 6-specific cDNA clones, gene 6 RNA segment was separately purified from the agarose gel.

cDNA synthesis, cloning and identification of VP6 gene-specific clones

In vitro polyadenylation of the denatured dsRNAs, synthesis of cDNA on the oligo(dT)-tailed plasmid (pCDV) primer, construction of cDNA library in *E. coli* HB101 were described previously²²⁻²⁵. The cDNA library, constructed for segments 5 to 9, was screened with ³²[P]-labelled mixed cDNA probe for segments 5, 6, 7, 8 and 9. Gene 6-specific cDNA clones were identified by Southern blot hybridization of the BamHI-digested plasmid DNAs with either the cDNA probe prepared from purified RNA segment 6 or the RNA probe prepared by labelling at the 3' end using *E. coli* poly(A)-polymerase²⁵. Several clones containing inserts ranging in size from 600 to 1500 nucleotides (nt) were identified. Clones OB67 having an insert of 1.0 kb and OB48, OB49 and OB68 containing inserts of 1.5 kb were used for further analysis. Although the reported length of gene 6 from group A rotaviruses is 1356 nt, the observed size of 1.5 kb can be attributed to the presence of poly(dA) and poly(dG)-tails of variable length at the 3' and 5' ends of the cDNAs respectively.

Nucleotide sequence analysis

The complete nucleotide sequence of gene 6 was determined from partial and full length cDNA clones. The cDNA inserts from the original clones were subcloned at BamH I site of pBluescript KS⁺ (pBSKS⁺) vector (Stratagene, CA, USA). From pBS67, subclones were generated utilizing internal sites for restriction endonucleases Nhe I, Pst I and Xba I. Sequence of both strands of the inserts in the subclones was determined using KS, SK and gene-specific primers. Nucleotide sequence was determined by dideoxynucleotide-mediated chain termination method²⁶ using sequenase version 2.0. Sequence near the 5'-end of the inserts in the original clones was determined using Okayama and Berg vector-specific primer. Nucleotide and the deduced amino acid sequences were analysed using version 6.1 of the GCG application software at the Distributed Information

RESEARCH ARTICLE

Centre, Indian Institute of Science. The sequences of the oligonucleotide primers are: 5'-ATCACAACCAGCTCATGAT-3' from nt position 527 to 545; 5'-TTAACTACAGCTACAAT-3' from nt position 675 to 691; 5'-GAAGTGTTACTTCTGCTCT-3' (5' primer for Okayama and Berg vector).

Expression in E. coli and purification of VP6

For VP6 expression, the T7-promoter – and the polymerase – based expression system was used²⁷. As the complete gene 6 cDNA contained 5' and 3' untranslated sequences, the gene 6 ORF was amplified by polymerase chain reaction (PCR)²⁸ using primers corresponding to the 5' and 3' ends of the ORF. The primers contained sites for restriction enzymes of convenience. The sequence of the 5' primer is 5'-GATATCAAGCTTCCCGGGATGGATGTCCTGTACTC-3' and that of the 3' primer is 5'-CTGCAGAAGCTTTTGGACAAGCATGCTTCT-3'. Gene 6 specific sequence is underlined. The PCR-amplified DNA was digested with Hind III and inserted at the Hind III site of pET20b(+) vector²⁷ (Novagen, Madison, WI, USA). The resulting construct is named as pETG6. To express VP6 without the pelB leader sequence, pETG6 was digested with Nde I and Sma I and religated after blunting the Nde I end by Klenow fill-in reaction. Deletion of the pelB leader sequence as well as the stretch of 17 aa downstream of it (upstream of the gene 6 AUG codon) brings the gene 6 AUG codon to within the requisite distance (10 nt in this case) from the Shine-Dalgarno (SD) sequence²⁹. This construct was represented as pETNDG6. *E. coli* HB101 cells were transformed with the ligated DNA and the plasmid DNAs from positive clones were used to transform *E. coli* BL21 (DE3)²⁷. Expression of VP6 in pETG6 and pETNDG6 recombinants was examined by analysis of the cell lysates by SDS-polyacrylamide gel electrophoresis (SDS-PAGE) as previously described³⁰. The recombinant VP6 was purified by single-step affinity chromatography using Ni²⁺-NTA-agarose as described earlier²⁴.

Production of polyclonal antiserum and immunoblot analysis

About 500 µg of the recombinant VP6 protein purified from the Ni²⁺-NTA-agarose column was electrophoresed on a 12% preparatory SDS-polyacrylamide gel. The 46.4 kDa band corresponding to VP6 was excised after staining with Coomassie blue and homogenized in 1 ml of phosphate-buffered saline. Polyclonal antibodies were raised by injecting the gel suspension into a New Zealand white rabbit subcutaneously at multiple sites as previously described²². Pre-immune serum collected

from the same rabbit before immunization was used as control.

Purity of the column-purified recombinant VP6 as well as the specificity of the polyclonal antiserum was determined by immunoblot analysis of the protein³¹. Western blots containing either the total cell lysate or the affinity-purified protein were first incubated with either the anti-VP6 antiserum or the SGI-specific mAb 255/60 and then with the secondary antibodies, goat anti-rabbit IgG or goat anti-mouse IgG conjugated with the horse radish peroxidase, respectively. For detection of VP6 by the SGI mAb, the gel was soaked in renaturation buffer (50 mM Tris.Cl pH 7.4, 20% glycerol) for 20 min prior to blotting onto nitrocellulose membrane. The antigen antibody interaction was detected by colour development in citrate buffer containing 3,3'-diaminobenzidine tetrahydrochloride and H₂O₂. The SGI-specific mAb 255/60 was originally produced using rhesus rotavirus (RRV) as the immunizing virus⁷ and provided by Dr Harry B. Greenberg, Stanford University, USA.

Immunoprecipitation

Individual colonies of BL21 (DE3) containing either pETG6 or pETNDG6 were grown overnight in M9 medium. The cultures were then inoculated into fresh sulfate-free M9 medium at 100-fold dilution and grown until the OD₆₀₀ reached 0.4. The cells were then induced with 0.4 mM IPTG in presence of 10 µCi of [³⁵S]-methionine per ml for 10 min at 37°C. The cells were harvested, lysed and inclusion bodies were prepared as described earlier²⁴. The inclusion bodies were dissolved in 0.1 M Tris.Cl pH 8.5 buffer containing 8 M urea by incubating at room temperature for 30 min. Urea was removed from the lysate by centrifugation through a centricon 30 column at 5000 rpm for 30 min. The protein solution remaining in the column was diluted with a buffer containing 10 mM Tris.Cl pH 8.0 and 100 mM NaCl. The process was repeated 3 to 4 times and the final fraction remaining in the column was used for immunoprecipitation. About 50 µl of the protein solution was diluted to 300 µl with RIPA buffer and incubated on ice with 5 µl of mAb 255/60 for 1 h after which 200 µl of protein A-sepharose CL-4B suspension (5 mg of dry gel) was added. The radioactively labelled recombinant VP6 bound to the resin was analysed on a 12% SDS-polyacrylamide gel and the bands were detected by autoradiography as previously described³².

Results

Nucleotide sequence analysis of gene 6 from the symptomatic G2 serotype Indian strain IS2 revealed that the

[illegible]

Figure 1. Comparison of the deduced amino acid sequence of IS2 VP6 with VP6 from other group A rotaviruses. Species origin of the rotavirus strains and the SG specificity of each of the strains are indicated on the left side of the corresponding VP6 sequence. Only the aas that differ from IS2 VP6 are shown. The numbering corresponds to the VP6 from majority of the strains that contain 397 aas. VP6 from the equine strain H2 is 399 aas in length and contains a two-aa insertion at position 296. The IS2 gene 6 sequence was submitted to EMBL database with accession number X94617.

Table 1. Per cent nucleotide and amino acid sequence identities of IS2 VP6 with VP6 from other group A rotaviruses

Rotavirus strain	Species origin	SG	nt	aa
IS2	Human	I	—	—
UK	Bovine	I	94.48	98.74
RF	Bovine	I	93.84	97.73
SA11	Simian	I	87.30	97.23
S2	Human	I	86.74	97.23
1076	Human	I	86.60	98.49
LP14	Lamb	I	85.51	98.24

Wa	Human	II	79.10	91.18
YM	Porcine	I	78.78	90.43

gene was 1356 nt in length. The gene contained a 5' untranslated region (UTR) of 23 nt followed by a long ORF with an AUG codon from position 24 to 26 and a termination codon from position 1215 to 1217. The ORF is followed by a 3' UTR of 139 nt. The ORF codes for a polypeptide of 397 aa with an apparent molecular weight of 44.87 kDa which is similar to that from other group A rotaviruses⁵ (Figure 1). The initiation codon at nt position 24 has the optimal sequence context for a strong initiation codon³³. There is no polyadenylation signal, AAUAAA, in the 3' UTR which is a characteristic of the genomes of the members of the family Reoviridae³⁴.

Comparison of the nt and the deduced aa sequences of gene 6 of IS2 with those of other strains showed a high

RESEARCH ARTICLE

degree of conservation of the SGI VP6 from different strains (Figure 1). The homologies for SGI VP6 ranged from 94.5% to 85.51% at the nt level and 98.74% to 97.23% at aa level (Table 1) with the exception of the porcine Ym VP6. The nt percentage homology with SGII VP6 from different strains was significantly low. Interestingly, IS2 gene 6 shared greatest sequence identity at both nucleotide and amino acid levels (94.48 and 98.74%, respectively) with that from the UK strain of bovine rotavirus and showed less identity (86.74% at nt and 97.23% at aa levels) with the SGI VP6 from the G2 type human strain S2 (Table 1). Majority of the prolines and the three cysteines at positions 96, 197 and 331 are conserved in VP6 belonging to all the subgroups indicating their importance in the proper folding of the protein. The Ile at aa position 56 and Ser at 120 that are conserved in all the SGI and SGI/II VP6 proteins are believed to contribute to SGI specificity³⁵. Ala at positions 172 and 305 that determine SGI specificity are also conserved³⁶ in IS2 VP6. The aa sequences from 58 to 62 (NWNFD) and 159 to 165 (PYSASFT) that determine group-specific epitopes are also conserved³⁷ in IS2 VP6 (Figure 1).

The most striking observation was that the IS2 VP6 contained substitutions by lysine at aa positions 97 and 134 (Figure 1). In all other strains, irrespective of the subgroup, Met at 97 and Glu/Asp at 134 are highly conserved^{35,38} (Figure 1). Also, IS2 VP6 contained a Leu at position 371 in contrast to Ile present at this position in all other group A rotaviruses (Figure 1). The isoelectric point of IS2 VP6, as determined by the programme ISOELECTRIC, was found to be more basic pI (6.68) compared to that of the VP6 from all other group A rotaviruses which ranged from 5.50 to 6.08 with the sole exception of the SGII VP6 from RV3 which had a pI of 7.03.

VP6 was expressed at high level in *E. coli* BL21 (DE3) using the pET20b(+) vector. While an expected 46.4 kDa band was detected in cells transformed with pETNDG6, two polypeptides of molecular weight 50.4 kDa and 48.0 kDa were observed in cells transformed with pETG6 (Figure 2). pETNDG6 lacks the pelB leader as well as the stretch of vector sequence encoding 17 aas preceeding the HindIII site in the vector. Thus the two polypeptides expressed from pETG6 might represent the leader-uncleaved and leader-cleaved forms of the VP6. It appears that the system is overburdened with the recombinant protein and only a fraction of the expressed protein underwent cleavage liberating the 48 kDa VP6 that contained the carboxyterminal six histidines. Inefficient cleavage of the pelB leader has also been observed previously by others³⁹. Alternatively, the 48 kDa species could represent VP6 initiated at an internal AUG codon, most likely that at the NcoI site located downstream of the pelB leader sequence. The fact that only the expected 46.4 kDa protein was expressed

Figure 2. Expression of IS2 VP6 from pETG6 and pETNDG6 in *E. coli*. Soluble fractions of the total cell lysates from cells containing pET, pETG6 and pETNDG6 (lanes 1, 3 and 5, respectively) and the corresponding insoluble fractions (inclusion bodies) of the lysates (lanes 2, 4 and 6) were analysed by SDS-PAGE and the gel was stained with Coomassie blue. Lanes 7 and 9 contain VP6 extracted from the inclusion bodies in 8 M urea and lanes 8 and 10 represent the urea-insoluble fraction. M, protein molecular weight markers. Note that the recombinant VP6 was found only in the insoluble fraction at any time after induction with IPTG.

from pETNDG6 in the absence of the pelB leader sequence strongly suggests that the 48 kDa protein expressed from pETG6 is derived from the 50.4 kDa precursor by cleavage of the leader sequence. The 46.4 kDa protein represented about 12% of the total protein. Clear mobility differences between the 48 kDa and the 46.4 kDa bands could not be detected in this size range in the mini gels used for electrophoretic separation (Figure 2) but mobility differences could be detected when electrophoresis is continued for longer period.

The recombinant protein expressed from either pETG6 or pETNDG6 and purified by affinity chromatography using Ni^{2+} -NTA-agarose resin, upon SDS-PAGE and staining with either Coomassie blue or silver nitrate showed another band of approximately 34 kDa (Figure 3, lane 3 and Figure 4). Silver staining of the gel also revealed another band of approximate size of 24 kDa (Figure 3). These low molecular weight species represent the carboxy terminal half of the protein as they

Figure 3. VP6 expressed in *E. coli* forms oligomeric structures. VP6 from the inclusion bodies was solubilized in 8M urea and the urea was then removed by gradient dialysis in presence (lane 3) or absence (lane 2) of β -ME. The proteins were separated by SDS-PAGE after heating at 100°C for 10 min in sample buffer containing (lane 3) or lacking (lane 2) β -ME. The gel was stained with silver nitrate. Lane 4 represents total insoluble fraction and lane 5 contains soluble fraction of the lysate from cells containing pETNDG6. Faint bands of high molecular weight forms of VP6 are seen in lane 2. Also the 24 kDa band is clearly seen in the reduced sample upon silver staining.

contained the histidine tag and could have arisen due to proteolytic cleavage or by internal initiation of translation at Met codons located at nt positions 321 and 552 or 561, respectively.

VP6 expressed in *E. coli* formed inclusion bodies as soon as it was synthesized, probably due to its intrinsic property to form multimeric structures. Studies on induction for varying time periods and with different concentrations of IPTG (0.1 μ M to 0.4 mM) revealed that VP6 expressed at as early as 1 to 10 min of induction was present only in the insoluble fraction. At no stage could we detect VP6 in the soluble fraction of the cell lysate even by immunoblot analysis using polyclonal antiserum.

VP6 from inclusion bodies was examined for oligomeric association and for the presence of the conformation-dependent SGI-specific epitopes. VP6 from the inclusion bodies was solubilized in presence of 8 M urea and the protein was allowed to refold by gradual removal of the urea by dialysing against buffer containing successively decreasing concentration of urea. The soluble protein so obtained was subjected to SDS-PAGE in presence or absence of β -ME (Figure 3). In the ab-

sence of reducing agent, faint bands of higher molecular weight forms corresponding to dimers and trimers could be seen even after heating at 100°C upon silver staining (Figure 3, lane 2), indicating that VP6 expressed in *E. coli* forms oligomeric structures. When the same was not heated (in the presence or absence of β -ME), much of the protein appeared as a smear in the size range between 150 and 80 kDa (data not shown). But upon heating (lane 2) in the absence of β -ME, much of the protein dissociated into the monomer though significant amount also remained in the oligomeric forms. These results suggest that VP6 expressed in *E. coli* existed in different conformational states probably due to rapid formation of insoluble complexes. As observed in the native viral protein and that expressed in insect cells⁴⁰, the recombinant VP6 exhibited anomalous mobility (smaller than the expected 46.4 kDa) as well as heterogeneity in the 46.4 kDa region in the absence of β -ME, suggesting the presence of intramolecular disulphide bridges within the monomer (Figure 3, lane 2).

To determine the authenticity of the protein as well as the presence of the conformation-dependent subgroup I-specific epitopes on the recombinant protein, total lysates in Laemmli buffer were subjected to SDS-PAGE and immunoblot analysis. As shown in Figure 4 B, the recombinant protein was recognized by the SGI-specific mAb 255/60, indicating that the recombinant VP6 contained epitopes that are conformationally similar to those of the native protein in the virion. This is further substantiated by immunoprecipitation of the solubilized radioactively labelled protein with the SGI mAb 255/60 (Figure 4 C). Both polyclonal and monoclonal antibodies recognized the 50.4 kDa, 48.0 kDa, 46.4 kDa and 34 kDa polypeptides while the 24 kDa species could not be readily detected, probably reflecting a lack of all the regions that determine the SGI epitope in this polypeptide (Figure 4 A and 4 B). The intensity of the VP6 band observed in immunoblot and immunoprecipitation analyses (Figure 4, panels B and C) using the SGI-specific mAb 255/60 was not commensurate with the amount of protein used for analysis, reflecting that only a fraction of the VP6 contained conformational epitopes similar to those observed in the native protein.

Discussion

As part of our ongoing studies on the genetic and antigenic variation/diversity in rotaviruses circulating in Indian population, we determined the nucleotide sequence of the SGI-specific intermediate capsid protein VP6 from an Indian strain of symptomatic human rotavirus IS2. As observed in other rotaviruses, the VP6 gene from IS2 is also highly conserved. Comparative sequence analysis revealed that the IS2 VP6 shared greatest sequence identity with the SGI VP6 from the bovine

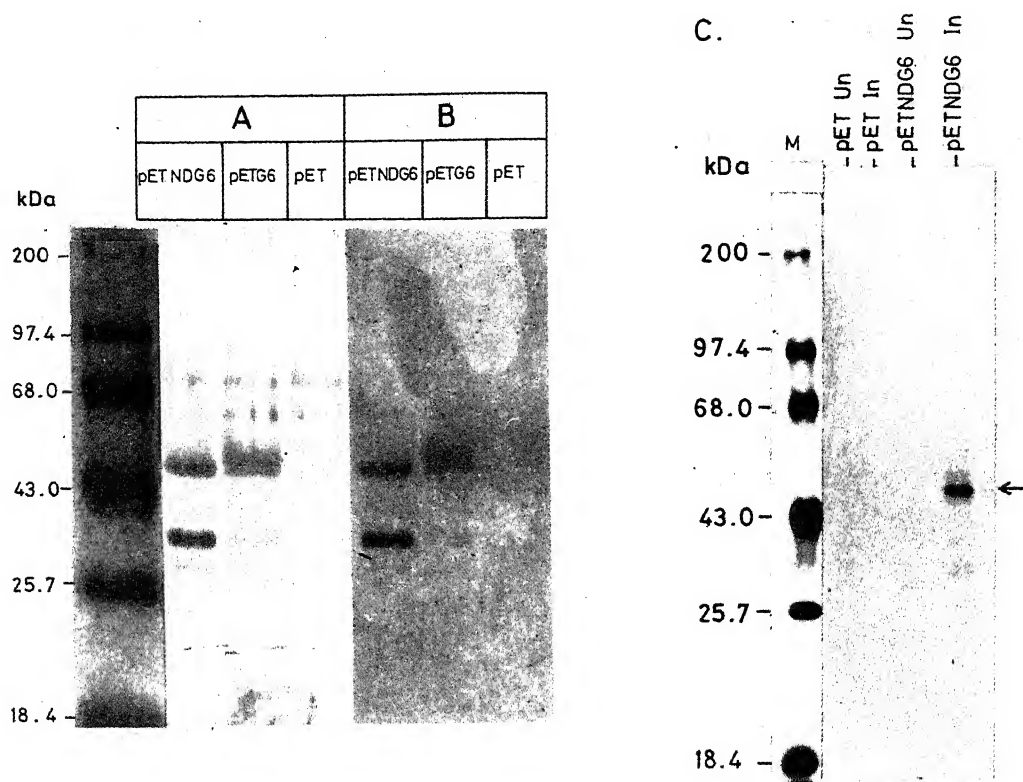

Figure 4. Immunological analysis of VP6 expressed in *E. coli*. Total bacterial cell lysates in Laemmli buffer containing β -ME were electrophoresed on a 12% SDS-polyacrylamide gel. In panel A, the proteins were directly blotted onto a nitrocellulose membrane. In panel B, the proteins were allowed to renature by soaking the gel in renaturation buffer as described in materials and methods. The recombinant VP6 in panel A was detected using polyclonal antiserum raised against the gel-eluted VP6 and in panel B, the SGI-specific mAb 255/60 was used for VP6 detection. Note that the polyclonal antiserum cross reacts with some bacterial proteins migrating above the VP6 band. The small molecular weight 34 kDa protein is also recognized by both polyclonal and monoclonal antibodies. In panel C, the radioactively labelled protein was immunoprecipitated with the SGI-specific mAb 255/60. Un, uninduced, In, induced.

UK strain and exhibited 94.48 and 98.74 per cent nt and aa sequence identities, respectively. Interestingly, IS2 VP6 shared significantly less nt sequence identity (86.74%) with the SGI VP6 from another human strain S2, though the per cent aa sequence identity was 97.23 (Table 1). These observations suggested that the VP6 gene in the Indian IS2 strain of human rotavirus most likely originated from a bovine rotavirus through genetic reassortment in nature. This is not surprising because in earlier studies in our laboratory we have isolated a large number of G10P11 type strains, from asymptomatic neonates in Bangalore and Mysore^{18,41}, that are reassortants between a G10P11 bovine rotavirus and a human rotavirus^{9,18,42}. Recently we have also reported isolation of strains having 'long' RNA pattern and SGI specificity from children with diarrhoea that are likely to have animal origin but distinct from the G10P11 type asymptomatic strains⁴¹. A G9P11 type asymptomatic reassortant rotavirus has also been reported from New Delhi⁴³. Thus it is possible that IS2 and the related serotype G2 and

G2-like strains circulating in India⁴¹ are also reassortants in which the VP6 gene is derived from a bovine rotavirus.

Substitutions by lysine at aa positions 97 and 134 in IS2 VP6 are interesting in the context of the reported substitution by acidic amino acids at several positions in IS2 VP4 (ref. 22). These complementary mutations in IS2 VP6 and VP4 might be of evolutionary significance in stabilizing the interaction between these two proteins in the virions of G2/G2-like Indian strains. Moreover, the presence of clusters of conserved basic amino acids in VP6 from aa position 100 to 154 suggests a functional role for this region.

Though the SGI VP6 from the simian virus SA11 was expressed in *E. coli* as a fusion protein, in insect cells as well as by recombinant vaccinia virus in MA104 cells, expression of VP6 from a human rotavirus has not yet been reported. Using the pET expression system, we have expressed the IS2 VP6 in nonfusion form at high levels and purified by single-step affinity chromato-

phy using Ni^{2+} -NTA-agarose as the matrix. The observation that the recombinant VP6 expressed in *E. coli* formed inclusion bodies as soon as it was formed is not surprising from the fact that majority of the VP6 expressed in insect cells was also found to form insoluble complexes^{40,44}. One of the reasons for the accumulation of VP6 expressed from pETG6 in the unprocessed form could be the nonavailability of the protein for processing due to aggregation as soon as it was synthesized. Alternatively the system is limited to process large amounts of the recombinant protein.

Native VP6 exists as trimer³⁸. There were conflicting reports on the nature of interactions between the monomers in the trimeric form of VP6. Gorziglia *et al.*³⁸ reported involvement of hydrophobic and charge interactions between the monomers in the VP6 trimer in the virion and disulphide bonds in intramolecular organization and hexamer formation. But Estes *et al.*²⁰ reported existence of disulphide bonds between the monomers in the trimer formed from the VP6 expressed in insect cells which was similar to the native VP6 in biochemical and immunological properties. In the present study, VP6 expressed in *E. coli* was found to be capable of forming oligomeric structures (dimers and trimers) and to possess both inter and intramolecular disulphide bridges as observed by Estes *et al.*²⁰.

Although VP6 represents the intermediate capsid protein, it is the major antigen of rotavirus and infected individuals have high-levels of antibodies against VP6. This is probably due to the fragility of the outer capsid resulting in the exposure of VP6 as well as the high abundance of VP6 in the virion compared to other viral proteins. Thus VP6 represents ideal candidate antigen for detection of rotaviruses in clinical samples. Coexpression of VP6 with VP2 or VP7 in the presence or absence of VP4 in insect cells has been shown to result in the formation of double-layered and triple-layered virus-like particles (VLPs), respectively, which are similar to the native particles and have been proposed as candidates for vaccine development⁴⁵. VP6 being an excellent immunological carrier¹⁶, availability of VP6 in large quantities should facilitate its use in vaccines as well as studies on the structure and mapping of the domains of interaction with the spike protein VP4.

Undernutrition and aging: Effects on DNA repair in human peripheral lymphocytes

Kalluri Subba Rao, Surekha Ayyagari,
N. S. Raji and K. J. R. Murthy*

Department of Biochemistry, School of Life Sciences, University of Hyderabad, Hyderabad 500 046, India

*Mahavir Hospital and Research Centre, Hyderabad 500 018, India

Subjects of Indian population belonging to 3 age groups – young (8–14 yrs), adult (20–35 yrs) and old (≥ 55 yrs) were divided into 'normal' and 'undernourished' groups based on Body Mass Index (BMI) and history of diet consumption. DNA repair markers like unscheduled DNA synthesis (UDS), activities of DNA polymerase β and two endodeoxyribonucleases, (UV- and AP-DNases) were studied in the lymphocytes of these subjects under different conditions. The 'undernourished' group showed higher activities of these enzymes and also a reduced decline in age-related DNA repair capacity. These results provide evidence for beneficial effects of reduced calorie consumption in humans as well.

THE integrity of DNA, maintained by a number of DNA repair systems, is essential for the survival of cells and organisms^{1,2}. Numerous physical and chemical factors damage DNA *in vivo* with their origin being both endogenous and exogenous. The resultant DNA damage has been associated with various biological end points, including cancer, mutation, birth defects, aging and other age-associated diseases³. A positive correlation has been claimed between maximum life span and the capacity to repair UV induced DNA-damage, both across species^{4,5}, as well as within and among closely related species^{6–9}.

In a different direction, dietary restriction (DR) is the only environmental paradigm that has been demon-

strated to increase maximum achievable life span in a variety of species^{10–13}. DR has also been reported to modulate the rate or eliminate the occurrence of almost all age-associated degenerative diseases. Furthermore, it is well documented that DR reduces the incidence of both naturally occurring and induced tumours^{14–19}.

It is possible that the mechanism behind the beneficial effects of dietary restriction is positive affectation of DNA repair potential by that regime. Reports, from this laboratory as well as from elsewhere, have indicated that DR does lead to improved DNA repair capacity in experimental animals^{20–22}. However, such effects are yet to be demonstrated in humans. We have therefore, taken up a study on healthy subjects (both sexes) of Indian population living in their natural conditions, with no familial history of organic defects and premature deaths, and belonging to 3 age groups, young (8–14 yrs), adult (20–35 yrs), and old (≥ 55 yrs). At each age, the subjects were divided into two groups of 20 numbers each: one group referred to as normal (NBMI) in which the individuals with a Body Mass Index (BMI)²³ of around 20 or more are included. The other group consisted of individuals with a low BMI of 18 or less (LBMI). Care is taken to see that the range is 16–18 with only a few subjects (5 out of 60) showing marginally lesser than 16.

Table 1 a. Average BMI of experimental subjects

Age	Average BMI	
	N	UN
Y	22.5 \pm 1.3	16.5 \pm 0.5
A	21.5 \pm 1.8	17.1 \pm 0.7
O	23.0 \pm 2.2	17.0 \pm 0.7

Subjects, based on their BMI, were categorized as 'normal' (BMI ≥ 20) and 'undernourished' (BMI ≤ 18). The average BMI of the subjects (20 nos) in the various age groups are shown, where N = Normal (NBMI) and UN = Undernourished (LBMI). Y – subjects grouped as 'young' (8–14 yrs); A – subjects grouped as 'adult' (20–35 yrs); O – subjects grouped as 'old' (≥ 55 yrs).

Table 1 b. Clinical parameters studied in experimental subjects

		Serum cholesterol (md/dl)	Blood haemoglobin (g%)	Random blood sugar (mg/dl)	Serum total protein (g/dl)	Serum albumin (g/dl)	Serum globulin (g/dl)
Y	N	155.2 ± 25.2	12.0 ± 1.1	83.0 ± 10.9	6.9 ± 0.53	4.3 ± 0.62	2.6 ± 0.43
Y	UN	145.8 ± 22.5	11.8 ± 0.4	83.0 ± 12.7	6.9 ± 0.48	4.1 ± 0.51	2.7 ± 0.50
A	N	180.0 ± 27.2	14.5 ± 1.3	76.0 ± 11.5	6.7 ± 0.79	4.6 ± 0.91	2.5 ± 0.45
A	UN	150.2 ± 26.2	13.6 ± 0.8	81.0 ± 27.0	6.5 ± 0.77	4.3 ± 0.93	2.3 ± 0.64
O	N	171.5 ± 26.8	13.8 ± 0.4	79.0 ± 14.0	6.5 ± 0.57	4.0 ± 0.43	2.4 ± 0.50
O	UN	163.0 ± 33.8	13.0 ± 1.4	82.0 ± 31.4	6.7 ± 0.98	4.2 ± 1.10	2.4 ± 0.60

Clinical parameters studied in experimental subjects were Hematology: Total leukocyte count, differential leukocyte count, total erythrocyte count, packed cell volume, blood hemoglobin; Biochemistry: Random blood sugar, serum cholesterol, serum total proteins, serum albumin, serum globulin; Others: Hepatitis B surface antigen detection, chest X-ray, electro-cardiograph. The mean values of clinical examinations of 20 individuals in each group are given. The differences, if any, between any two groups were not found to be statistically significant, where Y = young, A = adult, O = old, N = normal (NBMI), UN = undernourished (LBMI).

Figure 1. Basal DNA repair in peripheral lymphocytes of human subjects as a function of Body Mass Index at young (a), adult (b) and old (c) ages. Linear regression analyses are shown inside plot-box; $b(0)$ = intercept on y-axis; $b(i)$ = slope of the regression curve; r^2 = regression coefficient. At each age, 40 independent values are plotted.

Figure 2. Ultraviolet light (UV) induced fold increase in DNA repair in the peripheral lymphocytes of human subjects as a function of Body Mass Index at young (a), adult (b) and old (c) ages. Linear regression analyses are shown. Other details are the same as in Figure 1.

Figure 3. MNNG-induced fold increase in DNA repair in peripheral lymphocytes of human subjects as a function of Body Mass Index at young (a), adult (b) and old (c) ages. Linear regression analyses are shown. Other details are the same as Figure 1.

The average BMI of the subjects in the various age groups are shown in Table 1 a. Since the subjects were selected after careful examination of their familial and dietary history (most of these subjects belong to lower to upper middle class society and largely belong to either this university community or old age homes with a steady income behind them) and extensive clinical examination (data shown in Table 1 b), the low BMI value is taken to indicate a chronic but natural intake of low calories. Thus this LBMI group is assumed to be similar to an experimentally diet-restricted animal and therefore considered as 'undernourished' without any apparent malnutrition. Lymphocytes from these subjects were examined for various DNA repair parameters under different conditions.

Table 2. Basal and induced UDS in peripheral lymphocytes of human subjects with normal BMI (normal) and low BMI (undernourished) at different ages

Status	Basal repair	Induced repair	
		UV	MNNG
<i>Young:</i>			
Normal BMI	7.3 ± 3.7	83.4 ± 36.2	70.6 ± 33.6
Low BMI	9.2 ± 4.3	123.2 ± 49.9*	106.7 ± 46.0*
<i>Adult:</i>			
Normal BMI	6.5 ± 4.5	43.0 ± 29.9	35.3 ± 22.6
Low BMI	11.2 ± 5.8*	117.4 ± 50.1*	110.6 ± 62.0*
<i>Old:</i>			
Normal BMI	5.3 ± 4.5 [†]	27.6 ± 27.2	21.4 ± 17.6
Low BMI	11.4 ± 10.7*	87.3 ± 78.8*	78.6 ± 76.0*

Values are expressed as femtomoles of [^3H]-thymidine incorporated per μg DNA and represent average from 20 individual experiments. Unscheduled DNA synthesis (UDS) is measured as follows: Lymphocytes at a concentration of $10^6/\text{ml}$ in RPMI-1640 medium with 2 mM glutamine, 100 IU/l penicillin, 100 $\mu\text{g}/\text{l}$ streptomycin and 10% fetal calf serum, were incubated with and without 5 mM hydroxyurea (HU) and 5 $\mu\text{Ci}/\text{ml}$ [^3H]-thymidine (specific activity - 17Ci/mmol) for 2 h in a CO_2 incubator at 37°C with 90% humidity. The radioactivity incorporated into DNA was measured by standard procedure⁴⁴. The radioactivity in the cells incubated with HU is taken as the measure of UDS (DNA repair). *These values are significantly different from those of corresponding age matched NBMI group at a p value of ≤ 0.05 . † This value is significantly different from that of NBMI group of 'young' age at a P value of ≤ 0.05 .

Lymphocytes from anticoagulated blood of the subjects in the above groups were isolated by Ficoll-paque density gradient centrifugation^{24,25} and the unscheduled DNA synthesis (UDS), which is a measure of DNA repair, was examined in the peripheral lymphocytes. For the statistical analysis the Student's t test (paired) was used and the results are shown in Table 2. The basal DNA repair in NBMI subjects is decreased by 27% in old age as compared to 'young'. The difference among the young and adult groups was found to be not significant. In the LBMI group, however, no significant difference was noticed in the basal repair capacity among the three age groups and also the values at adult and old ages were higher than the corresponding age matched normals ($p \leq 0.05$). When the lymphocytes were challenged with a mutagenic treatment of exposure to either ultraviolet (UV 254 nm, $20 \text{ J}/\text{m}^2$) irradiation or to 50 μM of *N*-methyl-*N'*-nitro-*N*-nitroso-guanidine (MNNG), there was a response in the groups by way of increased UDS. The increased UDS due to this mutagenic treatment is also shown in Table 2. In normal individuals, there is a decrease in this response with age. However in the case of LBMI individuals, the response was always higher as compared to the normal group and this trend was similar in all the three age groups studied. This is to be expected because the LBMI groups already

had a higher level of basal repair and when this is coupled with the better response to mutagenic challenge, the result is a distinctly improved DNA repair capacity in LBMI subjects.

The DNA repair capacity as revealed by UDS is also examined as a function of BMI in each of the age groups by generating computerized regression curves (Sigma plot program, version 2.01), where BMI values are plotted against DNA repair. Figure 1 *a*, *b* and *c* show the regression analyses for 'young', 'adult' and 'old' age groups along with 95% confidence limits. As can be seen, BMI, therefore the nutritional status, has practically no correlation with DNA repair level in young, weak correlation in adult, but significant correlation in old. In line with this, the differences between the average values of low BMI group and normal BMI group at different ages were statistically significant at $P \leq 0.05$ level (Table 2). Similar regression analysis curves are shown for the UV (Figure 2) and MNNG (Figure 3) induced fold increase in DNA repair as a function of BMI at all the three ages. It can be seen that there is always an inverse correlation, albeit to varying degrees, depending upon the age and the mutagen employed, between the BMI and the fold increase in DNA repair. In all these analyses, only the basal DNA repair in 'young' has failed to show any relation with BMI.

These results with human subjects are in good agreement with the findings of earlier workers on experimental animals when dietary restriction was shown to improve the unscheduled DNA synthesis in lymphocytes, hepatocytes and kidney cells in rats²⁶⁻²⁸.

DNA repair in mammalian cells is a complex process involving many gene products²⁹. The overall process consists of recognition of the damage, excision of the damaged portion, resynthesis of the excised portion and finally ligation of the last nucleotide gap. Several endonucleases/protein factors were identified for the recognition of the damage and incision at the damaged site²⁹. During the past several years, we have identified two major endodeoxyribonucleases, one with an acidic pH optimum and the other with alkaline pH optimum, in rat brain. Detailed studies on the properties of these enzymes suggested a role in DNA repair at the initial incision step. The enzyme with acidic pH optimum was able to attack UV irradiated DNA while the second enzyme with alkaline pH optimum could attack a variety of damaged DNAs including apurinic/apyrimidinic DNA (AP-DNA)^{30,31}. An endonuclease acting on UV irradiated DNA and an AP endonuclease have been shown in mammalian tissues/cells including brain^{32,33}. Similarly DNA-polymerase β , generally considered to be a repair enzyme especially in base excision repair and also shown to be induced against damage to cellular DNA^{34,35} is found to be the major polymerase in adult brain^{36,37}. We have recently shown that the activity of this enzyme decreases in the aging rat brain possibly due

Table 3. Basal (BA) and UV induced (IA) DNA-polymerase activity in peripheral lymphocytes of subjects with normal BMI and low BMI at different ages

Status	DNA polymerase activity	
	BA	IA
<i>Young:</i>		
Normal BMI	395 \pm 167	732 \pm 350
Low BMI	424 \pm 158	911 \pm 386
<i>Adult:</i>		
Normal BMI	204 \pm 51	361 \pm 109
Low BMI	249 \pm 63*	421 \pm 113
<i>Old:</i>		
Normal BMI	136 \pm 69	240 \pm 160
Low BMI	204 \pm 69*	362 \pm 171*

Values are expressed as picomoles [³H]-TMP incorporated per mg of protein per hour. DNA polymerase assay: The preparation of cell extracts and assay was carried out according to the procedure of Nagasaka and Yoshida⁴⁵, which is optimally suited for measuring the DNA-polymerase β activity. Other details are as in Table 2. *These values are significantly higher than those of corresponding NBMI group at a P value of ≤ 0.05 .

to post-translational modification of the enzyme molecules³⁸. In view of this information, we have measured the activities of DNA polymerase β , UV DNase and AP DNase as markers of DNA repair potential in the lymphocytes of the subjects under study.

The activities of DNA polymerase β in lymphocytes with and without UV challenge are shown in Table 3. There is a decrease in the basal activities in both the normal and LBMI subjects, as age progresses, but the enzyme levels are significantly higher in the LBMI when compared to normals in adult and old age groups. Even under induced conditions, the pattern remained the same in that while the age dependent decrease is there in both groups, the values were always higher in LBMI group. However, statistical analysis showed that only in the old age the differences between NBMI and LBMI groups were significant. It can be seen that at old age the values in LBMI group are 50% higher than those in NBMI group. The activity profile observed in cells stimulated with phytohemagglutinin (PHA) and with and without UV challenge was also seen to follow a similar pattern (data not shown). The observed increase in basal DNA repair (Table 2) in the LBMI group at adult and old ages may be attributed to these enhanced activities of β polymerase. It is interesting that Srivastava and Busbee³⁹ have shown that both α and β polymerases of calorie restricted aged mice exhibit a higher level of fidelity than polymerases of *ad libitum* fed aged mice.

The activities of two DNases, UV DNase and AP DNase, in the lymphocytes of the subjects are shown in Table 4. An age associated decline in basal levels of UV DNase is seen among the normal subjects. The LBMI

Low BMI	222 ± 68*	260 ± 64*	237 ± 55*	276 ± 72*

Values are expressed as μg of DNA-P liberated per mg DNA and are the averages of 20 individual experiments. DNases assay: UV and AP DNases were assayed essentially according to the procedure of Rao and Rao⁴⁶. Substrate for UV DNase: UV DNA prepared by UV irradiation of highly polymerized calf thymus DNA (2 mg/ml) at a dose of $2 \times 10^4 \text{ J/m}^2$ using Phillips TUV 8 15 W germicidal lamp. Substrate for AP DNase: Depurinated DNA prepared essentially as described earlier⁴⁷. Native calf thymus DNA (2 mg/ml) mixed with equal volume of depurination buffer (40 mM sodium citrate, 40 mM NaCl, 40 mM potassium phosphate, pH 5.0 incubated at 70°C for 15 min). Other details are as in Table 2.

*These values are significantly higher than those of the corresponding NBMI group at a P value of ≤ 0.05 .

group at young age showed marginally higher values which were not statistically significant. However, at both adult and old ages, the values were significantly higher in LBMI group as compared to normal. Also the age-dependent decline seen in normal individuals is not evident in the LBMI individuals. A similar pattern of changes is seen even after the lymphocytes are exposed to UV except that the values are higher.

In the case of AP DNase, the pattern of changes in basal activities is similar to UV DNase. UV exposure of the lymphocytes resulted in comparable induction of this activity in both normal and LBMI groups at all ages, but in old age both the basal as well as induced activities in LBMI groups were significantly higher than those in NBMI group. Thus the overall picture seems to be that either the activities are unaffected or higher in LBMI individuals.

Age-related decline in UV-induced DNA repair has been reported in human peripheral lymphocytes^{40,41} and also in tissue from the central nervous system⁴². The present results while confirming the age-dependent decline in the activities of DNA repair enzymes also show that human subjects with low BMI presumably facing chronic low calorie consumption exhibit either unaffected or even improved activities with the age-dependent decline being distinctly slower.

This is the first study of its kind on human subjects to demonstrate the beneficial effects of chronic undernutrition, a phenomenon reported earlier in experimental

animals²⁶⁻²⁸. Walford and his group are conducting an elaborate experiment to examine the effects of diet on general physiology of humans including aging⁴³. These experiments are still continuing. However the present study is planned and executed with a population that is naturally available in India. The results indicate the possibility of a very intriguing and interesting phenomenon that LBMI (moderate undernutrition with no apparent malnutrition) is actually beneficial in human subjects in maintaining good DNA repair capacity. How undernutrition is able to achieve this is a matter of speculation. It is logical to expect that in LBMI individuals the cellular metabolism would be at a low ebb. However, even against this reduced calorie availability, the cell might choose to maintain certain essential pathways at normal rates and DNA repair pathway could be one such pathway in view of its cardinal role in protecting the genomic integrity. This in itself may be a major contributing factor for improved longevity in such human subjects.

A simple technique to expose tree seedlings to elevated CO₂ for increased initial growth rates

A. S. Devakumar, M. Udayakumar and T. G. Prasad

Department of Crop Physiology, University of Agricultural Sciences, GKVK, Bangalore 560 065, India

Initial growth rates of most tree species that are used in afforestation programmes are very low. Therefore, polybag planted seedlings have to be maintained in the nurseries for a long period of time. Growing plants in an elevated CO₂ atmosphere increases the growth rates as well as biomass production in many annual crop and tree species. Higher temperature and relative humidity in association with elevated CO₂ concentration helps to boost the biomass and leaf area production. We demonstrate here an easy and cost-effective method for obtaining elevated CO₂ concentrations for better growth of tree seedlings in the nursery.

APART from maintaining a balanced ecosystem, forests are major sinks of CO₂. Deforestation and burning of fossil fuel (due to population pressure) are the two major reasons for accumulation of CO₂ in the atmosphere leading to global climate change. Currently the CO₂ concentration in the atmosphere is around 360 ppm and it is increasing at the rate of 1.8 ppm per year¹. Hence afforestation is a practically feasible way to address the global climate change, especially in tropical countries where forest felling is occurring at a faster rate.

Figure 1a, b. Set up of the CO₂ enrichment system used for growing seedlings under elevated CO₂ concentration. a, Depicts the polythene cover enclosing the seedlings inside the trench; b, Cross-sectional view of the trench in which seedlings are kept and enclosed to expose to elevated CO₂ concentration. Floor of the trench is spread with decomposed organic matter. A metal frame is placed on the trench that supports the polythene cover to enclose the seedlings.

For any successful afforestation programme it is necessary to produce robust and healthy seedlings. Growing plants under elevated CO₂ concentrations has proved to enhance the biomass production². For obtaining elevated CO₂ concentrations, there are different systems available. Depending upon the need and purpose, one can select the desirable type of CO₂ enrichment system. These include, closed systems in controlled environment cabinets, 'Solardome' glass house, open top chambers, FACE (free air CO₂ enrichment), etc³.

There are advantages and disadvantages associated with these methods. However, one major constraint in most of these techniques is the high cost involved to expose the plants to elevated CO₂. In the present study we have developed a simple and economic technique to grow polybag seedlings under elevated CO₂ concentrations obtained from decomposition of organic matter. We demonstrate its successful use in obtaining increased growth rates in thirteen tree species at seedling stage.

Rectangular trenches of 3 m length, 1.25 m width and 0.6 m depth, were made in a place exposed to open sunlight. All the four sides of the cut ends of the trench were provided with a single layer of brick lining to avoid sliding of the edges. Inside the trench a layer of well decomposed organic matter was spread uniformly all along the floor. 16 kg of organic matter was required for the trench of above dimension to get a CO₂ concentration of 700–750 ppm (Figure 1).

A rectangular metal frame was placed over the trench completely enclosing it. The frame was fabricated using hollow galvanized iron tube of 1.5 cm diameter. Height of the frame was 1.6 m with a gable roof. Using high density polythene sheet of 125 μ gauge, a cover was tailored to suit the size of the frame. Length of the polythene cover was 12 inches longer than the frame so as to allow a free and flat fall on the ground after enclosing the metal frame. On this free lying polythene, a thin layer of sand was poured to keep the complete system air tight.

In this system we made use of the CO₂ produced by decomposition of organic matter spread on the floor of the trench. CO₂ thus released was trapped in the polythene chamber and a concentration of 700–750 ppm was obtained. Seedlings were exposed to higher concentrations of CO₂. Polybag seedlings were arranged in the trench so that the leaves of adjacent plants did not overlap and cause mutual shading (Figure 1b). Seedlings were exposed to elevated CO₂ between 3.30 pm and 11.00 am. Before closing the trenches water was sprinkled on the organic matter to stimulate soil respiration. Polybag seedlings were also watered before closing the chamber. In this system, apart from CO₂, relative humidity and temperature also built up inside the chamber.

Photosynthetic photon flux (PPF) over a wavelength of 400–700 nm, CO₂ concentration and relative humidity were measured using LI-6000 Portable Photosynthesis system (LI-Cor Inc, Nebraska, USA). PPF measurement inside the trench was made at 15 cm below the roof of the polythene structure. Temperature inside the trench and ambient air were measured simultaneously. Leaf area was measured using portable leaf area meter (LI-3000, LI-Cor Inc, Nebraska, USA). The thirteen species studied were – *Annona squamosa*, *Zizyphus jujuba*, *Tamarindus indica*, *Acacia auriculiformis*, *Derris indica*, *Spathodia campanulata*, *Feronia elephantum*, *Artocarpus integrifolia*, *Swietenia microphylla*, *Eucalyptus citriodora*, *Tectona grandis*, *Dalbergia latifolia* and *Dalbergia sissoo*.

Carbon dioxide concentration inside the trench started to build after enclosing the trenches at 350 ppm and reached 700–750 ppm in less than an hour. It remained high all through the night and started decreasing after sunrise in the morning (Figure 2). There was no difference in the concentration of CO₂ thirty minutes after closing the trenches in the air samples drawn from different heights inside the trench. In the morning, photosynthetically active radiation started increasing (Figure 3a) corresponding with the decrease in the CO₂ concentration inside the trench (Figure 2b), suggesting the utilization of higher concentration of CO₂ by the plants in the presence of sunlight for photosynthesis. Simultaneously, rise in the temperature inside the trenches was also more after sunrise (Figure 3b). An average of 1.21°C rise was seen inside the chamber compared to ambient air up to 8.00 am, while this difference from 8.00 am to 11.00 am was 4.69°C. Therefore, it was not possible to expose the seedlings for long periods after 11.00 am. Along with CO₂ and temperature, build up of relative humidity was also noticed inside the trench (Figure 3c). RH built up inside the chamber within thirty minutes after closing and reached the saturation level. It remained so till the trenches were exposed to open air, next day.

Using this system, seedlings of thirteen tree species were exposed to elevated CO₂, relative humidity and

temperature. Six-month-old seedlings were subjected to this treatment for ninety days and their responses were assessed to study the effectiveness of the system described.

There was a positive response to elevated CO₂ in biomass production, though the extent of response varied with the species. From this data it is evident that growth rates were better under elevated CO₂ concentration (Table 1). Among the various species, *Tectona grandis* showed the highest response to elevated CO₂ followed by *Dalbergia sissoo* and *Artocarpus integrifolia* in terms of biomass production. The total dry matter of *T. grandis* was 460 per cent more under elevated CO₂, compared to that of ambient air grown seedlings.

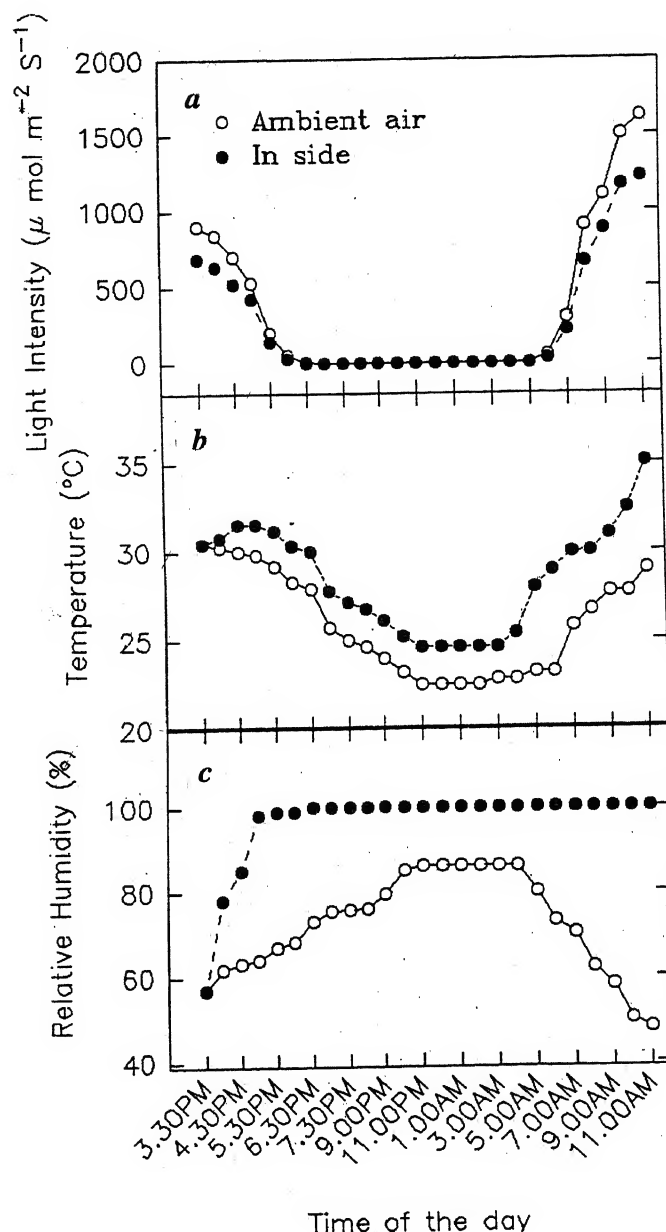

Figure 3a-c. Changes in (a) light intensity, (b) temperature and (c) relative humidity in the ambient air (O) and inside the chamber (●) for the period during which the seedlings were exposed to elevated CO₂ concentration.

The least responsive was *Tamarindus indica* recording only 12% increase (Table 1).

In this system, plants are making use of higher concentrations of CO₂ for carbon assimilation in the presence of light in the morning hours between 7.00 and 11.00 am. Evidences from a large body of literature show that it is possible to increase the biomass production by growing plants under elevated CO₂ (refs 2, 4, 5). In the present method of CO₂ fertilization, plants were

also experiencing relatively higher temperatures compared to ambient air grown plants. Imai and Murata⁶, noticed enhancement of leaf area and whole plant dry weight at higher CO₂ associated with higher temperature. Long⁷ has shown that proportionate increase in photosynthesis resulting from elevated CO₂ will rise with temperature. He also suggested that elevated CO₂ alters the magnitude of response of leaf canopy carbon gain to rising temperature and relative humidity which apparently enhances growth. It is likely that temperature and humidity associated with higher concentration of CO₂ must have helped in higher carbon assimilation and leaf expansion rates respectively.

Another important plant character that showed a remarkable increase under elevated CO₂ was leaf area per plant. A significant increase in leaf area was noticed among the species under elevated CO₂ when compared to ambient air grown plants (Table 2). All the species responded positively to elevated CO₂ concentration. An average of 228% increase in leaf area production was recorded under elevated CO₂ (mean of all the thirteen species studied). Similar type of studies conducted under controlled conditions have reported increase in leaf area in plants grown under high concentrations of CO₂ (refs 8–10). When higher temperature is associated with elevated CO₂ concentrations, leaf area is further enhanced¹¹. It is due to higher leaf initiation rate, leaf expansion and individuals leaf area. Saman *et al.*¹² have shown that leaf elongation rates were more under elevated CO₂ concentrations and were associated with

higher sucrose phosphate synthase activity during the early vegetative stage when growing blades were strong carbohydrate sinks. Leaf elongation rate is one of the ways by which leaf area development can be stimulated. Relative humidity is another important weather parameter that determines leaf growth. Elevated CO₂ concentrations, associated with higher temperature and RH might have influenced the leaf expansion rates. Relative humidity can reduce the vapour pressure deficits and thus help in maintaining high turgidity of the cells providing congenial conditions for cell division, elongation and expansion. Another possible reason for higher growth seen under this system could be due to lower dark respiration rates. According to Tanaka¹³, efficiency of respiration increases as a result of whole plant CO₂ enrichment. Decreased rates of respiration at higher concentrations of CO₂ was noticed^{14,15}. Even a small change in the respiration rate can have a considerable influence on assimilate retention and therefore its utilization for growth processes.

In the above method described for growing polybag seedlings of forest tree species, the main advantage is that there is no need of adding CO₂ from an external source, thereby reducing total cost considerably. Construction of the system is within the scope of a small workshop and material required is easily available. This system can be effectively used to enhance the initial growth rates of the seedlings specially forest tree species which have very poor growth rates. This can help in getting robust seedlings that may perform better when field planted and also helps in reducing the casualty.

Studies on molluscan diversity in Kaveri river system (Tiruchirappalli, India) with special reference to vector snails of trematode parasites

B. Amanullah and P. Shahul Hameed

Environmental Research Laboratory, Post-graduate Department of Zoology, Jamal Mohamed College, Tiruchirappalli 620 020, India

A monthly collection of molluscan animals was carried out from 11 sampling stations (K1-K11) of Kaveri river stretch from Karur to Grand Anicut (95 km) for a period of two years (April 1991–March 1993). 13 species of molluscs were recorded, of which 8 species were gastropods and 5 species bivalves. The gastropod species were grouped under 5 different families (Viviparidae, Thiaridae, Pilidae, Lymnaeidae and Planorbidae) and the family Thiaridae was the most dominant group representing 50% of the total gastropod population. Five species of bivalve molluscs were classed under 2 different families namely Unionidae and Corbiculidae. The mean density of molluscs was higher ($96/m^2$) in sector I (K1–K4) than in sector II ($39/m^2$) which include stations K5–K11. Five gastropod species were identified as carriers of the disease causing parasite cercarial larvae. The pulmonate snails were preferred most by trematode cercaria.

SEVERAL investigations were undertaken on major benthic animal groups of freshwater system. Notable contri-

butions to our knowledge of molluscan fauna have been made by several authors¹⁻⁵. Hoagland and Brown^{6,7} made an extensive investigation exclusively on gastropods. Relationship between gastropod density and vegetation has been reported by many authors⁸⁻¹⁰. Similarly bivalve species density has been studied by several workers¹¹⁻¹³. Srinivasan¹⁴ has reported three species of freshwater mussels in the Kaveri river system, namely *Lamellidens marginalis* (Lamarck), *L. conso-brinus* (Lea) and *Parreysia favidens* (Benson). However, an intensive study on molluscan fauna of the Kaveri river has not been made in recent times.

Freshwater snails are preferred intermediate hosts for cercaria larvae of trematode parasites¹³. A number of trematodes of horse, goat, sheep, camel, dog, buffalo and other cattle develop to cercarial stage in certain gastropod molluscs. They cause diseases and mortality in cattle. About 57 types of cercariae were recorded from the snail *Indoplanorbis exustus*⁵. The distribution of this snail was reported throughout the plains of India, Pakistan, Persia, Srilanka, Burma, Malaya, Indochina, Thailand, Sumatra, Java and Celebes⁵. Burch¹³ has also reported cercarial larvae in the two distinctly different freshwater snails in the Eastern African regions. Since these parasites caused considerable damage to the cattle wealth of the river basin¹⁵, the parasitology of these trematode worms assumed economic importance. Studies on the snails acting as vectors of disease causing trematode parasites in the Kaveri river are very limited¹⁶. Hence, an attempt has been made to identify the snail vectors of trematode parasites inhabiting the Kaveri river.

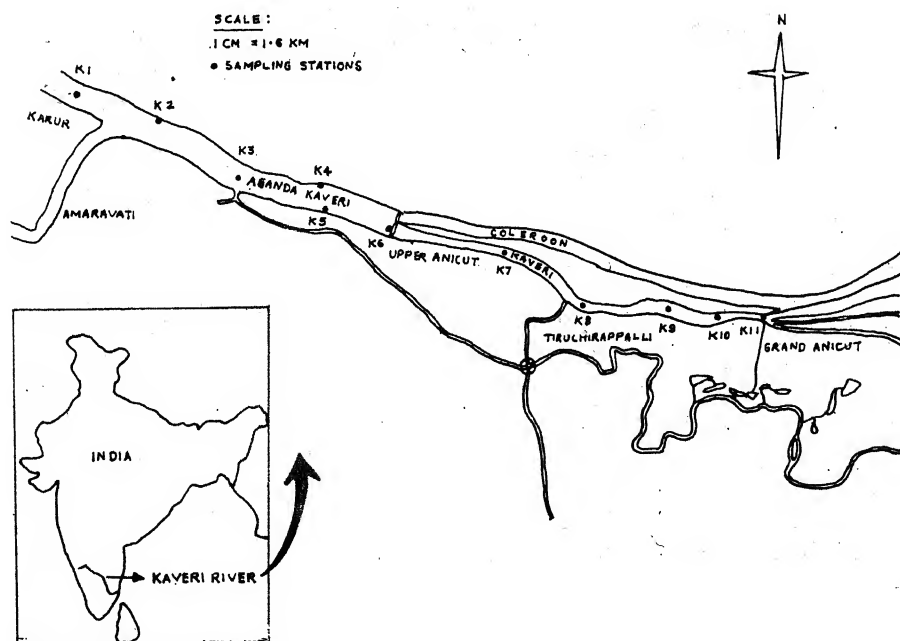

Figure 1. Location of the Kaveri river and sampling sites.

RESEARCH COMMUNICATIONS

A study on the molluscan fauna of the Kaveri river stretching from Karur to Grand Anicut at Tiruchirappalli (10°48'N and 78°42'E) was carried out for a period of 2 years from April 1991 to March 1993. The river stretch under study is a fifth order stream and broadest after receiving several tributaries. Eleven sampling stations (K1-K11) were fixed in the river stretch (Figure 1). The river stretch under study is divided into two sectors based on the degree of human interference, i.e. sector I (K1-K4) and sector II (K5-K11). The urban agglomeration of Tiruchirappalli is centred around sector II and hence, it is found to have higher human interference than sector I.

The molluscan animals were collected from 11 sampling stations of the Kaveri river system. Larger molluscan species were collected by hand picking and also sieving the river sediments by using coarse sieves. The bottom substrate and macro-vegetations were explored for collecting the most representative diversity of molluscs and they were identified. Snails associated with vegetation were collected by using hand net (150 µm). The hand net was dragged over the aquatic vegetation. When the net was filled with aquatic weeds, the contents were poured out on a spread out cloth piece. The population density of molluscs in a given area was studied using quadrat method as described by Subbarao⁵. The number of animals in the samples collected from wooden quadrant (0.5 × 0.5 m) was counted and value expressed as the number of molluscs per square meter (number/m²).

Snails were collected manually, using gloves to prevent cercarial infection. The collected snails were then transported to the laboratory in polythene bags along with weeds and water. Then the live snails were individually transferred to clean glass test tubes half filled with tap water and exposed to sunlight for discharge of cercaria from the snails¹⁷. The cercaria were transferred onto glass slides with fine pipette and observed under microscope. Some of the cercariae were fixed in 10% formalin stained with eosin or methylene blue mounted in DPX, and identified.

The present study revealed that the molluscan fauna of the Kaveri river were represented by 8 species of gastropod and 5 species of bivalves. The gastropod species are classed under 5 different families, viz. Viviparidae, Thiariidae, Pilidae, Lymnaeidae and Planorbidae; the family Thiariidae being more dominant and representing nearly 50% of the total gastropod population recorded in the Kaveri river (Figure 2). The identification of species was confirmed by the Zoological Survey of India, Calcutta. Certain species of gastropods such as *Bellamya dissimilis*, *Paludomus tanschaureicus*, *Thiara* sp., were found predominant in the Kaveri river throughout the year. Gastropod species such as *I. exustus*, *Lymnaea ovalis*, *P. virens* and *B. dissimilis* were associated with aquatic macrophytes.

Figure 2. Percentage of species composition of gastropod molluscs in Kaveri river stretch from Karur to Grand Anicut.

Table 1. Classification of molluscan fauna in Kaveri river stretch in Tiruchirappalli

Phylum	:	Mollusca
Class	:	Gastropoda
Subclass	:	Prosobranchia
Order	:	Mesogastropoda
Family	:	Viviparidae

Table 2. Seasonal variation in the molluscan faunal density in two sectors of the Kaveri river

Seasons	Sector I (no./m ²)	Sector II (no./m ²)
Premonsoon (April–July)		
1991–1992	242 ± 18	67 ± 14
1992–1993	88 ± 14	25 ± 8
Mean	126 ± 28	45 ± 23
Range	72 – 267	20 – 98
Monsoon (August–November)		
1991–1992	44 ± 12	23 ± 13
1992–1993	60 ± 17	25 ± 16
Mean	53 ± 13	23 ± 18
Range	24 – 92	14 – 42
Postmonsoon (December–March)		
1991–1992	139 ± 15	44 ± 13
1992–1993	77 ± 14	23 ± 8
Mean	110 ± 19	33 ± 15
Range	68 – 157	16 – 68
I year mean	115 ± 23	45 ± 12
II year mean	76 ± 24	33 ± 13
Annual mean	96 ± 29	39 ± 18
Range	24 – 267	14 – 117

Five species of bivalve molluscs belonging to 2 different families such as Unionidae and Corbiculidae were recorded (Table 1). The abundance of molluscan species was quantified at two sectors of the Kaveri river. The mean density of molluscs at sector I was 96/m² and it ranged from 24 to 267/m² and in sector II, the mean density of molluscs was 39/m² and it ranged from 14 to 117/m² (Table 2). The abundance of molluscs was significantly different between the sectors (ANOVA: $F = 21.45$; $P < 1\%$) whereas it was not significantly different within the sector (ANOVA: $F = 1.96$; $df = 23$; $P > 1\%$).

Eight species of gastropods recorded in the present study were tested for the presence of cercaria larvae. Five species namely, *Indoplanorbis exustus*, *Lymnae ovalis*, *Thiara tuberculata*, *T. scabra* and *Paludomus tanschauricus* were carriers of the cercarial larvae. Cercarial infection was more acute in *I. exustus* and *L. ovalis* than in other snail vectors of the Kaveri river. Since these parasites caused considerable damage to the cattle wealth of the Kaveri river basin, the parasitology of these trematode worms assumed economic importance. Identification of such intermediate snail host and effective control of snail population would be the best preventive measure¹⁵.

The present study also indicated that species of the Thiariidae such as *T. scabra* and *T. lineata* were found to prefer the pollution-free water and sandy bottom, which provide soft substratum for their easy penetration.

Therefore, they were predominantly recorded in sector I than sector II. Among the gastropod species, *I. exustus*, *L. ovalis*, *P. virens* and *B. dissimilis* were associated with aquatic weeds which provided food and shelter for those organisms. A similar study on correlation between aquatic weeds and molluscan abundance was made by Upatham¹⁸ in Thailand. Anwar and Siddiqui¹⁹ recorded 7 species of gastropods and 3 species of pelecypods in Kali river.

Molluscan groups such as gastropods and bivalves were found to be quantitatively most important groups and represented throughout the year^{20,21}. Kaul *et al.*⁹ reported that distribution of freshwater gastropods in Haigam, a typical wetland in Kashmir, had bearing on density of aquatic weeds.

Evidence of Archaean crustal shortening from deformed pillow lavas: An example from Sandur greenstone belt, Dharwar craton

C. Manikyamba and S. M. Naqvi

National Geophysical Research Institute, Hyderabad 500 007, India

There is a continuous debate about the autochthonous or allochthonous model of the evolution of the greenstone belts. We report here evidence which suggests that the Sandur greenstone belt of Dharwar craton is an allochthonous remnant of accreted oceanic volcanism. Pillow structures of the western margin of the Sandur Schist Belt have been compressed in NE-SW and stretched in N 40°-45°W direction. The length/width (L/W) ratio (X'/Y') of these elongated pillows varies from 3 to 30, transforming them to pencil shape with well developed schistosity. Poisson's ratio of the elongated pillows at uniaxial stress of 1.5 kb is 1:24, whereas that of undeformed pillows 1:10 or 1:14. Such compression has not been witnessed in the eastern part of the belt. Generally, pillows in Sandur and other greenstone belts in an undeformed state show length/width ratio varying between 1 and 2. The comparison of the L/W ratio of the elongated and normal pillows and their Poisson's ratios from the western and eastern parts show that 7 to 8 times shortening has taken place along the western margin of the belt. This shortening along the belt is interpreted due to horizontal compression, consequent of convergent margin movement and rock mass transport, implying their allochthonous character.

It has been frequently suggested that a modified form of plate tectonics (smaller plates) operated during the Archaean and, greenstone belts are allochthonous remnants of accreted oceanic crust, plateaus and/or island arcs¹⁻³. Most of the supporting evidences of this aspect are mainly based on the geothermal inferences, structural patterns and geochemical data from Canadian and South African greenstone belts. However, for the greenstone belts of Karnataka, India, the continental rift model was advocated^{4,5}, although oceanic crust-based origin of these belts has been demonstrated⁶⁻⁹. Recently¹⁰ it is suggested that the Dharwar greenstones were deposited in marginal or back arc volcano-sedimentary basins. These authors¹⁰ believe that the rocks in eastern Karnataka, including Sandur belt, formed as intra-arc basins above the evolving Dharwar batholith. Here we report evidence of horizontal compression, shearing and thrusting of volcanic rocks of oceanic origin and infer the consequent crustal shortening for the Sandur greenstone belt of Dharwar craton (Figure 1).

Sandur schist belt situated in the eastern margin of the Karnataka nucleus mainly consists of different types of metavolcanics and metasediments. The volcanic rocks are essentially tholeiitic basalts along with intermediate and acid volcanic rocks. These volcanics show well-developed pillow structures which on extensive deformation are elongated and stretched. The study of their stretching will provide a clue to the mechanism (process) of their deformation.

The pillow structures of the Deogiri and Donimalai formations at the western margin of the belt, south of Hospet, and south-west of Sandur (150 m thick across the strike) are stretched (Figure 2), whereas pillows of both the formations from the eastern part of the belt have normal length/width ratio (X'/Y') ranging from 1 to 2. More than 1200 pillows were measured at six places in the belt for their length, width, convexity and dip/inclination of the flow layers (Figure 1). Z' is exposed rarely and wherever exposed it is always less than X' and more than Y' ($X' > Y' > Z'$). The data are presented in the histograms depicting the variation in the L/W at each locality (Figure 3). All along the western margin of the belt, the pillows are compressed in NE-SW and stretched in N 40°-45° W direction. About 80% of the pillows have been stretched to give the length/width ratio ranging between 3 and 30, and 81% of the pillows have length/width ratio between 3 and 12 (Figure 3 a). The width (Y') of these pillows varies from 0.5" to 20", with 88% of the pillows having a width (Y') between 1" and 10" only. On the other hand, the length (X') of these stretched pillows varies from less than 10" to 190" (Figure 3 a). However, 72% of the pillows have length (X') more than 30" i.e. between 30", and 190". Most of them are stretched to such an extreme extent that they have a 'pencil shape' (Figure 2 a) appearance in a vertical or semivertical exposure where Z' is available. Some of the pillows have width between 4" and 6" and length between 40" and 60" with pointed ends. Large-scale variation in the overall size of the pillows even in stretched form is illustrated in Figure 2 b. Due to compression and metamorphism the recrystallization of original mineralogy into amphiboles and sodic plagioclase with development of well-defined axial plane schistosity has taken place (Figure 2 a). This schistosity is observed in individual pillows too. Although the texture and mineralogy show recrystallization, the deformed boundaries (rims) of the pillows are preserved with the general destruction of the convexity (Figure 2) and the flow layers have become almost vertical. A fracture system (cleavage) parallel to the compression direction has developed in most of the pillows. This indicates that the post-consolidation directional stress has been very effective on these pillows and other associated rocks (Figure 2 a) and continued to be active for a fairly long time. All along the belt the first generation axial plane cleavage (D_1 deformation) dips towards

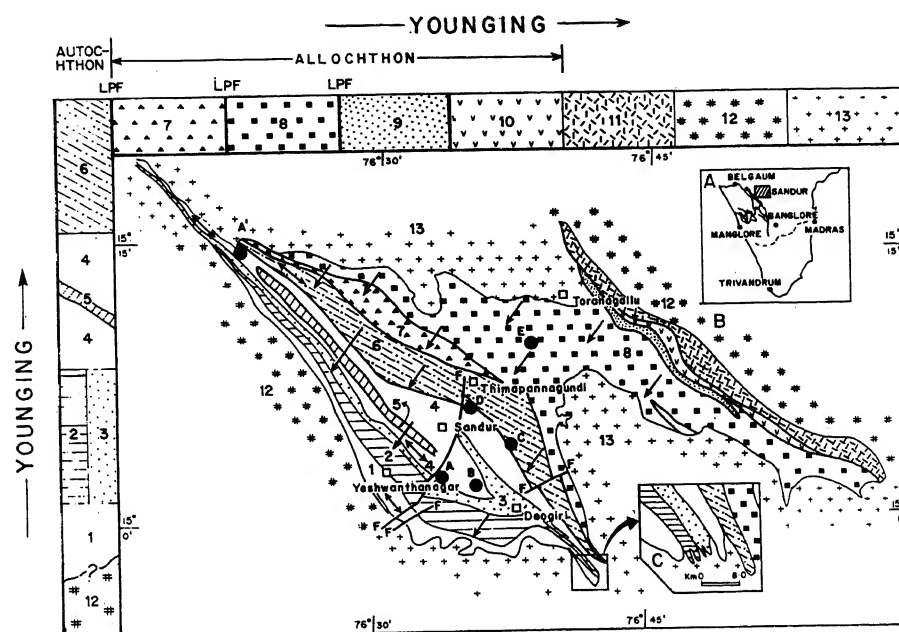

Figure 1. Geological map of the Sandur Greenstone (schist) belt, with a location map of India and the proposed stratigraphic succession. 1, Yeswanthanagar block (YB); 2, Deogiri block (DB interbedded with banded manganese formation); 3, Western volcanic block (WVB interbedded with banded iron formation); 4, Central volcanic block (CVB); 5, Greywacke; 6, Eastern volcanic block (EVB interbedded with banded iron formation); 7, North central acid volcanic block (NCAVB interbedded with active plate margin turbidites); 8, Sultanpura volcanic block (SVB); 9, Sediments of eastern volcanic block; 10, Eastern acid volcanic block (EAVB); 11, Amphibolites of eastern block; 12, Granitic gneisses and granites; 13, Younger granites.

Figure 2a, b. *a*, Stretched pillows, 5 km south of Hospet almost vertical plane. End of the individual pillows has become pencil shaped. F_1 axial plane schistosity and fracture cleavage are both visible; *b*, Stretched pillows from west of Sandur from spot A".

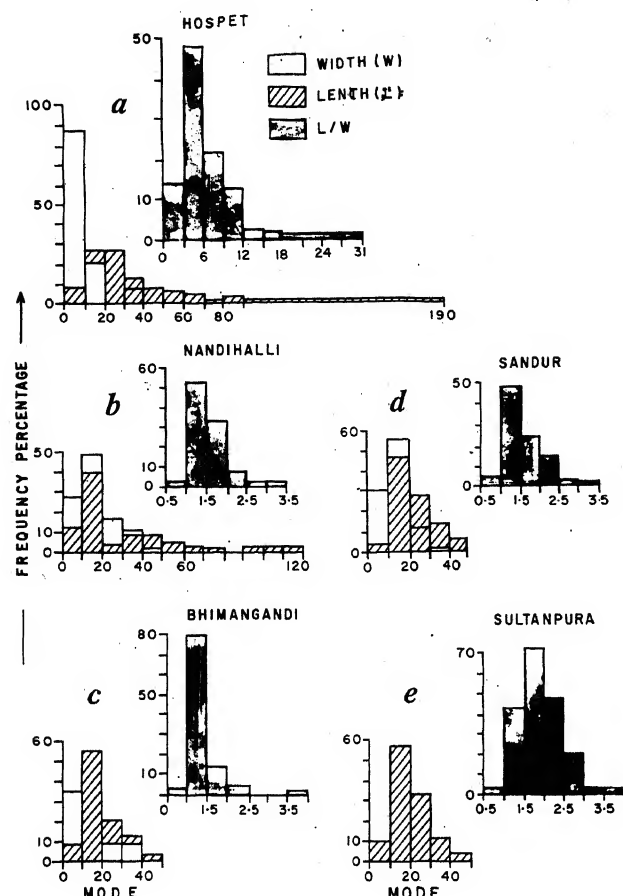

Figure 3a-e. Histograms showing the length, breadth and the length/breadth ratio of the pillows in different places in the Sandur schist belt.

north-east, indicating the compression direction (Figure 1). The pillows exposed in most of the eastern part of the belt do not exhibit this compression and stretching. Their length/width ratio generally remains between 1 and 2. Determination of length/width in the centre of the belt Nandihalli, south of Sandur (Figure 1, spot B) shows that 85.41% of the pillows have length/width ratio between 1 and 2, with 40% having length between 10" and 20" and 48% between 10" and 120" (Figure 3 b). There are giant pillows in this region which have length and width measuring up to 120" and 80", respectively. The relict mineralogy and igneous texture are found in many sections. In most of the sections, relict augite is found rimmed by amphibole. Plagioclase boundaries are not clear as the reaction between plagioclase and other minerals has not been completed. Chlorite, amphibole and epidote are found along these boundaries with fibrous development of actinolite being quite common.

Along the eastern part near Bhimangandi (Figure 1, spot C), 80% of the pillows have their length varying between 10 and 40", and 84% pillows have their width varying between 5 and 20" (Figure 3 c). Consequently,

Figure 4. Poisson's ratio showing axial strain and lateral strain at 1.5 kb. It can be seen that up to 3.55 and 34.37 lateral and axial strain, the ratio maintains between 1:10 and 1:14, i.e. the range of the plastic deformation for these rocks. From point A onward, post-consolidation deformation is indicated, resulting in the elongation of the pillows.

92% of the pillows have length/width between 1 and 2. Similarly, west of Sandur (Figure 1, spot D) in the eastern volcanic block 83.61% of the pillows have a length varying between 10 and 40", and 93.44% of the pillows have width between 5 and 30" (Figure 3 d). Therefore, 90.53% of the pillows have length/width ratio between 1 and 3 and 57% of them have this ratio between 1 and 2. Seldom anywhere in the eastern part of the belt does the length/width ratio of the pillows cross 3.5 or 4. Further east, after crossing the Eastern volcanic block (EVB) in Sultanpura block (Figure 1, spot E) there is considerable variation in the length and width of the pillows (Figure 3 e). Here 48% of the pillows have length varying between 10 and 20" with a maximum length of 60". Width of these pillows ranges up to 40" with 56% of them ranging between 10 and 20". Most of these pillows show convexity towards east and 90% of them have length/width ratio between 1 and 3 (Figure 3 e). This shows that in the entire belt, the maximum deformation, elongation and compression have occurred along the western part of the belt. The average reduction in the width of the pillows is around 7 to 8 times and the increase in the length also appears to be of the same order. This shows that at least 7 to 8 times crustal shortening in the NE-SW direction has taken place along the western margin. Similar elongated pillows have been noticed in the Nondweni greenstone belt, southern Kaapval Craton, South Africa, where a shortening factor of 100 has been suggested¹¹. Such zones of elongation and stretching are zones of high strain parallel to strike direction and represent thrusting.

Elastic properties of the elongated and normal pillows under uniaxial stress of 1.5 kb have been studied to understand the mechanical behaviour of lateral strain to axial strain (Figure 4). In undeformed pillows, the slope between lateral and axial strain remained nearly uniform, while in the elongated pillows the slope is distinctly different. The strain measurements indicate that the elongated pillows are brittle in their behaviour and the strain ratio is approximately 1:24, otherwise this ratio in case of undeformed pillows is 1:10 or 1:14. This change in the strain ratio appears to have been caused by the post-consolidation deformation during shearing and thrusting (Figure 4). Brittle deformation and development of fracture system almost at 90° to the schistosity is observed in most of the pillows.

Pillows are exposed in almost all late Archaean greenstone belts of Karnataka and other parts of the world¹² and the length/width measurements at other places such as Gadag and Ingaldhal in Chitradurga schist belt have confirmed that the length/width ratio of the normal undeformed pillows generally remains between 1 and 2. This increase in the length/width ratio along with change in the dip of the flows from 0 to 90°, almost vertical F_1 fold axis and the 20°–80° NE dip of the first generation axial plane schistosity are unequivocal evidence of horizontal compression and large-scale movement of the rock mass. Recently the 35 km thickness of the Sandur belt has been attributed to the thrust thickening¹⁰.

Under the P–T conditions of regional metamorphism (confining pressure), elongation of pillows would not have taken place, as in the case of other parts of the belt (Spot B to E, Figure 1). This suggests that in addition to confining pressure the lavas of the western margin were subjected to a directional stress, which continued to produce post-consolidation brittle deformation. This may mean that the lavas of western margin were part of a subducting slab and compression continued till the closing of the proto-ocean. Therefore, it is argued that the western margin of the Sandur belt has been overridden by its eastern part. Furthermore, geometry and the wavelength (2–10 m) of the D_1 fold closures at the northern and southern termination of the belt¹³ substantiate the inference that horizontal compression and crustal shortening have been a very significant and frequent aspect of tectonic evolution of this greenstone belt.

Palaeotectonic implication of Lamayuru lake (Ladakh)

T. N. Bagati, R. K. Mazari and G. Rajagopalan*

Wadia Institute of Himalayan Geology, Dehra Dun 248 001, India
*Birbal Sahni Institute of Palaeobotany, Lucknow 226 007, India

The age of ancient Lamayuru lake in Ladakh, Trans-Himalaya, has been speculative due to non-availability of proper date at the base of its sediment profile. A date of 35,000 ± 600 yr B. P. was reported by earlier workers in the upper part of lower sedimentary profile but precise timing of the development of lacustrine conditions is all important to know the origin of the lake and the question whether it was formed by normal geomorphic processes of slope derived debris damming or tectonically induced slope instability leading to river impoundment. The present study shows that the lake developed around 45,000 years ago, which coincides with a regional tectonic event in the Trans-Himalaya. The geomorphic processes were but adjunct to the intrinsic process of earth shaking during this episode of tectonic activity in the region. Timing of initiation and closure of lacustrine sedimentation in the Himalayan river valleys could offer an important clue for determining the recurrence interval of major earthquakes in the Himalaya. This calls for extensive work both in space and time.

THE late Quaternary remnant lacustrine deposits lying at an altitude of 3600 m in Lamayuru, Ladakh (Figure 1), comprise mudstone, siltstone and sandy shale facies

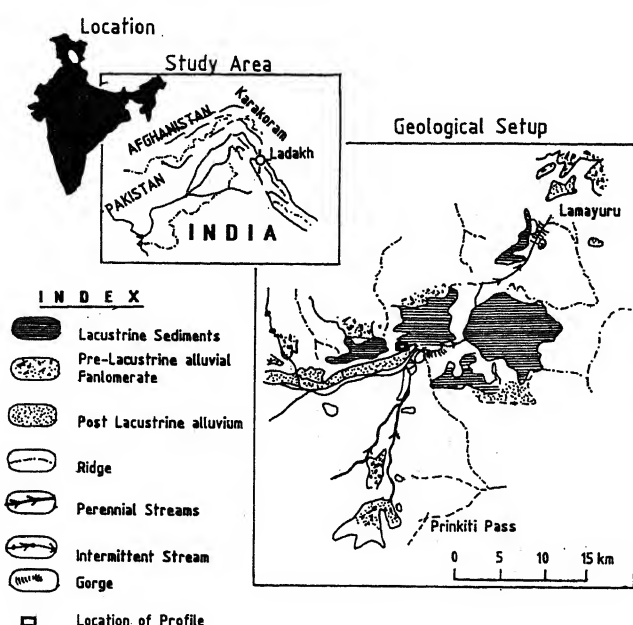

Figure 1. Geological map of the Lamayuru lacustrine sediments (Modified after Fort *et al.*³). The inset map shows location and the study area.

Figure 2. Lithosequence of Lamayuru lacustrine sediments at Rong-Gongkha.

resting over the prelacustrine fanglomerate. The sediments in the central part are rarely preserved due to extensive erosion and slumped blocks. The basement rocks are composed of argillaceous and calcareous Lamayuru flysch in the north, east and west of the basin, while the Tethyan carbonates are exposed in the south of the basin. The clay and silt contents of flysch have favoured post-lacustrine mass wasting processes including debris and rock slides in the proximal part of this ancient lake body. At present the climate of Lamayuru area is cold and dry and devoid of any vegetation except some scrubs.

In the present study, a 7.9 m profile of lacustrine sediments in the central part of the basin at Rong Gongkha has been investigated in detail (Figure 2). The base of the lacustrine fill lies on top of about 5 m thick fanglomerate which rests on the flyschoid basement rocks. The same profile was worked in detail by Sangode and Bagati¹ for palaeoclimatic studies using magnetic susceptibility and sedimentological parameters. The profile under investigation consists of five facies. These are: i) mudstone-siltstone, ii) mudstone-siltstone with charcoal, iii) mudstone-siltstone with small clasts, iv) sandy shale, and v) mudstone.

The mudstone-siltstone is the dominant facies occurring at various stratigraphic levels. In this facies mudstone is grey and shows parallel laminations. The thickness of laminae varies from 0.5 to 1 cm but increases in up section. The mudstone-siltstone with charcoal facies occurs at four stratigraphic levels. At places the charcoal is associated with mud pellets and is aligned parallel to the bedding. The mudstone is yellowish grey to ash-coloured and is generally laminated. The charcoal is generally associated with thick siltstone layers and shows grading. Some plant impressions were also observed in this facies. The charcoal fragments lying at 350–370 cm level were radiocarbon dated. The mudstone-siltstone with small clasts facies is present at two levels and shows grading. The clasts are generally associated with mudstone and oriented parallel to the bedding. Both intraclasts and extraclasts are present in this facies and represent turbidity deposits. The sandy shale facies is present at one level only in the upper part of the sediment profile. The laminae in this facies are 3–5 cm thick. It is yellowish grey and fine grained. The mudstone facies occupies the topmost part of the profile and shows parallel lamination.

In the central part of the basin the facies assemblage with charcoal and sedimentary structures indicate that density flows were responsible for deposition of silty turbidites. They are associated with sediments deposited under calm conditions and the deposition took place in a progressively deeper water body. The source for silty turbidites and sandy shale mudflows was probably from the Fotu La as indicated by the presence of large charcoal fragments within the lacustrine sediments exposed

Figure 3. Siltstone-mudstone containing charcoal fragments (dark patches).

in upper reaches of the main Lamayuru channel. The presence of charcoal with plant impressions (Figure 3) indicates that the source was very close to the site of deposition. Bagati and Thakur² are of the opinion that during this period the climate was warm and forests grew luxuriously. Hence forest fires were common in the catchment. The warm phase is further supported by magnetic susceptibility study of the sediments¹.

The charcoal fragments recovered from siltstone-mudstone facies at 350–370 cm level were dated by the ^{14}C method (BS-879). The sample has yielded a date of 40,000 yr B. P., the maximum range provided by ^{14}C method. In essence, the sample could be much older. There is no other date available in the profile, hence the timing of lacustrine sedimentation could not be worked out directly. A date of $35,000 \pm 600$ yr B. P. given by Fort *et al.*³ does not correspond with the present profile at its equivalent height and level since their profile lies far away from our site of investigation. Thus, the only method that could be applied for determining the commencement of lacustrine condition is the rate of sedimentation, but again there are limitations posed by non-availability of another radiometric date in the profile. Since this is significant for many reasons, we have used average rate of sedimentation calculated for the Tsokar lacustrine sediments on the basis of radiocarbon dates for core TP-6 (Figure 4) (ref. 4). The basis being that Tsokar and Lamayuru fall in the same geographical entity or geomorphological domain, which permits logical application of known sedimentation rate of the former to the latter where such data do not exist. Such an approach is based on a work where empirical equation of sediment yield in relation to catchment characteristics has been used to estimate the distribution of sediment yield in adjoining catchments of similar morphology⁵.

Figure 4. ^{14}C age vs depth of the sediment profile TP-6 from Tsokar lake. The rate of sedimentation, 1 m/1000 yr, is based on the linear regression line drawn through the data points (after Rajagopalan *et al.*⁴).

Thus by applying the sedimentation rate of Tsokar lake (approx. 1 m/1000 yr) to our profile from average point of 360 cm level where charcoal sample was recovered, we get a time frame of 3600 years to the base of the lacustrine sedimentation. Adding this figure to 40,000 yr B. P., we get a date of 43,600 yr B. P. for the commencement of the lacustrine phase. As Fort *et al.*³ postulate that the filling of the Lamayuru basin may have taken anywhere between 1000 and 10,000 years, we believe that attaining of full lacustrine conditions may have taken anywhere up to 2000 years or so. From this work we estimate that the initial damming of the erstwhile Lamayuru river took place probably somewhat prior to or near about 45,000 yr B. P. Due to the obliterated top sequence there is difficulty in calculating the closure of the lacustrine condition based on the rate of sedimentation. Hence more detailed work is required to answer this question. Assumptions based on discrete evidences, at this stage, have the risk of committing gross error.

The origin of the lake is attributed to tectonically induced slope instability in the basin, a sudden pulse of which mobilized large quantities of slope debris to dam the Lamayuru river. The episodic active nature of the lineament running parallel to the Lamayuru river is amply revealed in the narrow and deep cross profile developed after the depletion of the lake. The principal cause of blockade by periglacially derived debris as held by Fort *et al.*³ in this light appears substantially unconvincing. There are evidences where lake basins like Sumdo in lower Spiti valley were developed by high seismic activity in the region resulting in blocking of the river around 45,000 yr B. P. (ref. 6). Reactivation of the Nainital Fault around the same time⁷, though in a different tectonic domain, could be taken as an indirect clue for a major tectonic episode in the Himalaya. By analogy of

timing it is possible that the same event was responsible for the development of discrete lake basins in the Spiti valley⁸.

In conclusion it may be said that the Himalaya which registered its maximum uplift during Pleistocene experienced periodic regional tectonic impulses to account for impoundment of rivers, thereby leaving imprint of such evidences for posterity. The depletion of such lake basins could be either due to normal processes of erosion or triggering of post-blockade major tectonic impulses. Given this thesis, the timing of the depletion of lake basins on a larger regional scale assumes importance in determining the recurrence interval of catastrophic earthquakes in the Himalaya. Such an objective calls for extensive field work and dating of river valley lacustrine deposits along the length and breadth of the Himalaya.

Chemical ages of detrital zircon concentrates from the uranium-bearing basal quartz-pebble conglomerate of Dhanjori Group from six localities have been determined based on high precision analysis of U, Th and Pb. Three of the zircons gave concordant ages of 3044–3090 Ma, which represent the minimum age of the provenance rock and older age limit of Dhanjori sedimentation. The Singhbhum Granite Complex dating between 3.3 Ga (Phases I & II) and 3.12 Ga (Phase III) are the likely provenance rocks. Chemical ages, coupled with evidences from field relations and temporal nature of uranium-bearing QPCs suggest that the sedimentary members of Dhanjori Group are likely to be older than the presently assigned age of 2300 Ma.

THE Singhbhum–Orissa craton, eastern India, comprises of a complex geological assemblage of Archaean and Proterozoic age. Chronostratigraphic status of many of

the lithogroups in this craton, especially the Dhanjori Group and Iron Ore Group (IOG) are still debatable^{1,2}, mainly because of inadequate radiogenic ages. The occurrences of uranium-bearing basal quartz-pebble conglomerates (QPC) in both Dhanjori Group³ and IOG⁴ are important in this context. Detrital U-bearing QPCs the world over have distinct temporal and stratigraphic positions^{5,6} and are generally confined to Archaean–Proterozoic transition period. Among the detrital heavy minerals in such conglomerates, zircons, because of their highly refractory nature, are considered provenance diagnostic. The ages of detrital zircon in QPCs correspond to the age of the parent rock and thereby aid in establishing provenance and stratigraphic position of the QPCs. In this communication, we report U, Th and Pb contents of detrital zircons from some QPC horizons at the base of Dhanjori Group and their chemical ages.

The volcano-sedimentary sequence of Dhanjori Group began with a basal quartz-pebble conglomerate, followed by a thick sequence of fuchsite-quartzite and an occasional phyllite. Upper part of the sequence is an extensive basic volcanic sequence. Basal QPC is exposed intermittently along the south, east and western margins of the Dhanjori basin. Conglomerate samples for the present study have been collected from six localities; Butgora in the western margin; Phuljari, Jawardih and Asthakaoli in the southern margin; and Tirioburu and Chakri in the eastern margin of the basin (Figure 1).

Zircon, chromite, rutile, monazite, pyrite, etc. are the prominent detrital heavy minerals found in all the QPC samples. Zircons recovered from these samples are characterized by their coarse (mostly 200–250 µm), stubby, unzoned nature and pink colour (Figure 2). Systematic morphometric analyses of zircon grains

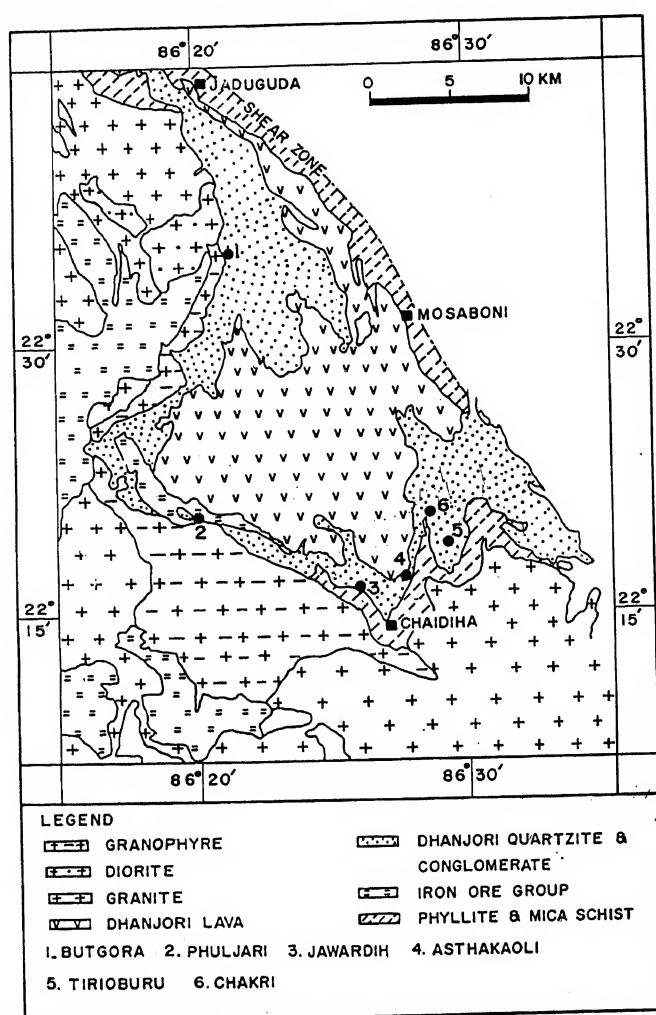

Figure 1. Geological map of Dhanjori basin (modified from Vasudeva Rao *et al.* 1988) showing the QPC sample locations.

Figure 2. Detrital pink zircons separated from the QPC sample from Jawardih.

reveal their uniformity in colour, habit, length-breadth ratio (1.9 to 2.1), etc. Uniform morphometric characters of zircons from various locations suggest a common provenance for the Dhanjori sediments.

Zircon-rich heavy mineral concentrates were obtained from crushed and ground QPC samples by tabling, followed by sequential heavy media separation. Magnetic separation of these concentrates on Frantz Barrier Pole Isodynamic separator yielded a zircon-rich non-magnetic fraction devoid of monazite. The non-magnetic fractions from Butgora and Phuljari contained abundant pyrite. These pyrites were converted to oxides by heating the samples to 800°C in a muffle furnace. These oxides were removed by further magnetic separation. Stereomicroscopic handpicking was resorted to ensure near 99% purity of the zircon concentrates thus obtained. Special care was taken during stereomicroscopy so that no monazite remained in the zircon concentrate.

The pure zircon separates were finely powdered and treated with conc. HNO_3 followed by conc. H_2SO_4 to remove coatings and inclusions if any. U was analysed by delayed neutron activation analysis (DNAA) after irradiating the samples and standards in the CIRUS reactor (neutron flux $10^{13} \text{ n} \cdot \text{cm}^{-2} \cdot \text{s}^{-1}$) and by γ -ray spectrometry of the daughter product Np^{239} . Th was analysed by INAA after irradiating the samples in Apsara Reactor (neutron flux of $10^{12} \text{ n} \cdot \text{cm}^{-2} \cdot \text{s}^{-1}$) for 4 h. γ spectra were taken using 125 cc HPGe detector coupled to PC based MCA system, having 30% efficiency with respect to $3'' \times 3''$ NaI detector and system resolution of 1.9 eV for 1332 keV of ^{60}Co . Pb was analysed by differential pulse anodic stripping voltametry. The errors in analysis were of the order of $\pm 5\%$ for U, $\pm 2\%$ for Th and $\pm 4\%$ for Pb. The U, Th and Pb content of the six samples of zircon are given in Table 1.

For calculation of chemical age, lead content in the sample is assumed to be of radiogenic origin by the decay of uranium (both ^{235}U and ^{238}U) and thorium. Non-radiogenic common lead content in zircons is shown to be as low as 0.01 ppm⁷; higher values of up to

Table 1. U, Th and Pb analyses of zircons from QPCs

Location	U (ppm)	Th (ppm)	Pb (ppm)	Th/U	Age (Ma)
Southern margin					
Jawardih	197	91	142	0.46	3090 \pm 124
Phuljari	148	70	80	0.47	2538 \pm 102
Asthakaoli	219	91	153	0.42	3048 \pm 122
Western margin					
Butgora	200	90	84	0.45	2109 \pm 84
Eastern margin					
Tirioburu	248	134	152	0.54	2745 \pm 110
Chakri	187	89	132	0.48	3044 \pm 122

Errors in estimations are $\pm 5\%$ for U, $\pm 2\%$ for Th and $\pm 4\%$ for Pb. Errors in age computation are $\pm 4\%$.

6.5 ppm have been reported only from rare magnetic zircons.

From the radioactive decay series of ^{238}U , ^{235}U and ^{232}Th , the atomic proportion of radiogenic lead in a mineral can be calculated⁸ using the following equation:

$$\text{Pb} = \text{U} \times [0.99276 (e^{\lambda_1 t} - 1) + 0.007196 (e^{\lambda_2 t} - 1)] + \text{Th}(e^{\lambda_3 t} - 1), \quad (1)$$

where U and Th are in atomic proportions. Modern abundance of ^{238}U is 99.276% of total U and that of ^{235}U is 0.7196%. The decay constants given by Jaffey *et al.*⁹ for ^{238}U ($\lambda_1 = 1.55125 \times 10^{-10} \text{ yr}^{-1}$, ^{235}U ($\lambda_2 = 9.8485 \times 10^{-10} \text{ yr}^{-1}$) and Th ($\lambda_3 = 4.9475 \times 10^{-11} \text{ yr}^{-1}$) are used in this calculation.

In this transcendental equation, t is the time duration in years and can be solved numerically. Bowles⁸ adopted an iterative approach of solution of this equation to calculate the age of uraninite. We have used the Newton-Raphson method of numerical analysis for solving this equation, for which the initial approximate age was obtained using the empirical equation

$$t = \ln \left(\frac{1.104 \text{ Pb}}{\text{U}} + 1 \right) \times \lambda_1^{-1}. \quad (2)$$

A computer program in FORTRAN has been written for solving eqn (1) by Newton-Raphson method (Appendix 1).

Chemical ages of the detrital zircons thus calculated are given in Table 1. Error in chemical age calculation is the cumulative manifestation of errors in chemical analysis, particularly of lead. Based on the errors in estimation of U, Th and Pb, the age calculated will have an error of $\pm 4\%$. Zircons from Jawardih, Asthakaoli and Chakri gave a very close age of 3090–3044 Ma. Tirioburu sample gave an age of 2745 Ma, whereas Phuljari and Butgora samples gave lower ages (2538 Ma and 2109 Ma respectively).

The lack of knowledge of non-radiogenic lead content leads to overestimation of age. But chemical ages calculated on individual uranium-bearing minerals having practically little initial lead content, using high precision analytical data^{8,10,11}, are found to be close to the isotopic age, and zircon is one such mineral. Since zircons from all the QPCs have similar optical and morphometric characteristics as well as similar U/Th ratios (see Table 1), it is reasonable to assume that their provenance is the same, and that the concordant age of 3044–3090 Ma obtained for three of the samples (Jawardih, Asthakaoli and Chakri) should be close to the age of the provenance rock. The lower ages of the samples from Butgora, Tirioburu and Phuljari are the result of natural lead loss or unintended lead loss that occurred during preparation of pure zircon separates. Though it is logical to assume that all the lead in zircon is radiogenic, post-crystalline lead loss, especially in broken zircon grains is definitely

a possibility¹², which would yield lower values in chemical age calculations. Accordingly, the concordant age of 3040–3090 Ma may be taken as the minimum age of the provenance rock. Isotopic age of zircons, and hence that of the provenance rocks, can be expected to be close to this age on the higher side, i.e., ≥ 3100 Ma, taking into account minor lead loss. The ≈ 3100 Ma, also represents the maximum age limit of commencement of sedimentation in the Dhanjori basin.

The heavy mineral suite of the Dhanjori QPCs is dominated by the presence of zircon, monazite and chromite. Quartz and quartzitic pebbles, abundance of detrital zircon and monazite, and geochemical characteristics of the QPCs including their REE pattern (paper under preparation) suggest the predominance of a granitic rock unit in the provenance for Dhanjori sediments. Detrital chromite suggests the occurrence of some ultramafic rocks also in the provenance. The palaeocurrent and basin analysis based on sedimentary structures, and textural maturity of the QPC, indicate a fluvial to deltaic depositional environment on a peneplained granite-greenstone terrain³. Among the probable older rocks of the Singhbhum craton that could be the source for zircons in the QPCs, the most widespread is Singhbhum Granite Complex belonging to three successive and closely related phases¹³. The other older rocks are the Older Metamorphic Tonalite Gneiss (OMTG) and Older Metamorphic Group (OMG). Singhbhum Granite phase III has been dated by Pb–Pb whole rock isochron method as 3130 ± 28 Ma and by Sm–Nd method as 3120 ± 100 Ma, while the Phase I is ≈ 3300 Ma old². OMTG rocks have been dated by Pb–Pb method as ≈ 3400 Ma¹⁴ or older¹⁵. The Pb–Pb age data on zircons from OMG¹⁶ gave ≈ 3550 Ma as the older age limit for OMG sedimentation. We have compared the morphometry of zircons in OMG samples from Champua and OMTG samples from Saraikela with those of Dhanjori QPCs and found that the Dhanjori zircons are distinctly different from those found in OMG and OMTG samples. On the other hand, several samples of Singhbhum Granite are found to contain appreciable amounts of zircon morphometrically similar to those found in Dhanjori QPCs¹⁷. It is reasonable to infer from these observations that the prominent source rock for Dhanjori Group sediments is Singhbhum Granite; however it is difficult to decipher at this stage whether Phases I and II (Singhbhum Granite A) are the major contributors or phase III (Singhbhum Granite B).

Dhanjori Group of rocks are assigned an age of ≈ 2300 Ma by Saha *et al.*¹⁸. However, the following considerations indicate that the sedimentary members of Dhanjori Group of rocks are likely to be older in age: (i) Uranium-bearing basal QPCs are generally confined to late Archaean-early Proterozoic transition period. (ii) The provenance rocks are of 3100 Ma or of older age. (iii) There is striking similarity in the geological

setting of QPC units of Dhanjori with Bababudans of Dharwar Super Group of Karnataka³, of age estimated¹⁹ to be between 3000 and 2800 Ma. The 555 m level crosscut of the Jaduguda uranium mine now exposes a continuous rock succession in the dip direction from Dhanjori metabasics through the uranium-bearing lodes to the schists and quartzites of Singhbhum Group. This conformable and continuous succession with Dhanjoris at the base also indicates that Dhanjoris are older than Singhbhum Group of rocks, an observation also made earlier by Mukhopadhyay²⁰ in the Rakha Mines. The Singhbhum Group of rocks has been assigned the age of c.2300 – 2400 Ma. It is also interesting to note here that the basal QPCs of IOG also contain detrital heavy minerals including zircons similar in character to those found in QPCs of Dhanjori. Because of these mineralogical similarities, we believe that the provenance of both IOG and Dhanjori Group was the same, and the sedimentation in IOG and Dhanjori basins was more or less coeval.

Annual Review of Physical Chemistry 1995. Vol. 46. Herbert L. Strauss ed. Annual Reviews Inc., 4139 El Camino Way, P.O. Box 10139, Palo Alto, California 94303-0897, USA. Price: USA \$ 51, elsewhere \$ 56. 771 pp.

Over the years, the editors and authors of the *Annual Review of Physical Chemistry* series have attempted to provide us with a broad definition of physical chemistry in an era of growing international collaborations and subsequent blurring of the sharp boundaries between disciplines. The present volume starts with reminiscences of a spectroscopist, William Klemperer who describes how physical chemistry (read spectroscopy) has grown in front of his and his colleagues' eyes at Harvard. He narrates how rotational spectroscopy in cold molecular beams has helped us understand interstellar chemistry. This introductory chapter, although well written, is more of a technical account than personal. We wonder if a scientist only remembers the scientific achievements of the past and not the personal incidents that were associated with it along with the personalities!

Most of the articles in the present volume deal with gas phase spectroscopy and dynamics of one kind or other. Herbst as well as Sims and Smith have dealt mainly with rates of gas phase reactions at low temperatures. Herbst's motivation being guided by chemistry in interstellar medium, he concentrates on ion-molecule reactions for generating exotic species and rules out the possibility of neutral-neutral reactions at the low temperature and density of the interstellar medium. Sims and Smith, on the contrary, discuss elementary chemical reactions of neutral reactants at temperatures as low as 13 K. Several examples of molecular energy transfer at low temperatures are discussed.

Gas phase photochemistry and dissociation/reaction dynamics are described, at least, in four experimental and five theoretical chapters. In his article, Bernstein describes intracluster electron and proton transfer, vibrational relaxation, predissociation and radical additions with suitable examples. Farrar has discussed ionic reactions with a special emphasis on proton and hydrogen atom transfer reactions of the atomic oxygen

anion. Gas phase S_N2 reactions have also been included. Mode-selective enhancement of chemical reactions of acetylene and ammonia cations with other species have been reviewed. Recent developments on two-dimensional imaging of a chemical reaction as it proceeds has been reviewed by Heck and Chandler. Quantum state distribution of a product and the velocity correlated to that distribution can simultaneously be measured by this new method. The authors present in detail how to convert the image into useful information. The instrumentation aspect has been emphasized so that the readers can follow the procedure with ease. This is an excellent article and discusses both orientation and alignment in uni- and bimolecular reaction processes. In another article, Loesch has reviewed recent progress in reactive beam collisions with special importance to orientation and alignment. Two techniques have been described, a brute force technique and an infrared laser-based optical technique, to orient and align molecules in a supersonic beam. The reactions of alkali metals with HF, ICl and CH_3X ($X=I$ or, Br) are discussed along with the relevant theoretical results.

Theoretical studies of polyatomic reaction dynamics have been illustrated by Bowman and Schatz. In this account, the authors have concentrated on four or more atom reactions. Currently, all efforts on experimental and theoretical fronts are focused on four-atom reactions in order to unravel the mechanism of these reactions. This is a timely review dealing with quantum and quasiclassical methods of calculating reaction rates and cross-sections. Adequate comparisons between theoretical and experimental results have been made in order to put the concerted world-wide efforts in this field in perspective. An equivalent but different approach of modelling three and four atom chemical reactions has been described by Jackson. The wave packet reactive scattering approach pioneered by Heller and improved by many has been discussed. Extension of the wave packet dynamics calculations to gas-surface reactions has been dealt with. In another article, Jolicard has discussed yet another method, the effective Hamiltonian for molecular dynamics calculations. This method, developed in the 1960s gained a lot of attention in the '70s. The

author has discussed the theoretical foundation in detail. Application of vibrational energy redistribution and photodissociation of van der Waals molecules, as well as femtosecond dynamics have been illustrated with examples. This is no longer a popular method and thus, the author specifically mentions the advantages offered by this method in his concluding remarks. The accuracy of full-quantum calculations in predicting spectra of hydrogen molecular cation and its isotopic variants has been reviewed by Leach and Moss. The hydrogen molecular ion is simple in the sense that electron correlation is not of concern in this species and a full quantum calculation can be carried out. The authors have deliberately limited the scope of this article to hydrogen molecular ions and stressed on the accuracy required to reproduce experimental numbers. This article will perhaps help the specialists in the field to learn the details of such calculations. Another theoretical article in this volume deals with analysis of molecular spectra. The excellent review by Kellman about algebraic methods in analysing spectra will benefit a large number of experimentalists. He describes the standard spectroscopic Hamiltonian as well as the more recent Lie algebraic techniques for fitting a detailed excited state spectrum. The application of algebraic Hamiltonians to complex spectroscopic problems has great advantages for the numerical task of fitting a spectrum, in comparison with trying to fit the spectrum to a potential energy surface. We hope that experimental spectroscopists critically evaluate this advantage!

Femtosecond pulse shaping and optical control have been discussed by Kawashima, Wefers and Nelson. This is a highly technical article, but we suppose, it would be helpful to those who are interested in coherent excitation in a short time-scale! Impulsive stimulated Raman scattering studies of coherent lattice vibrations in the solid state and impulsive one-photon absorption in atomic vapour have been discussed. Efficient photoinduced electron transfer in supramolecular and photosynthetic systems has been described by Franzen and Martin. They have included time-resolution of excited state vibrational motion, the electric field dependence of the quantum yield, and resonance Raman

and hole-burning experiments that probe the nature of the initially prepared excited state.

Laser cooling of neutral atoms to form a bound dimer between two free atoms has been discussed by Lett, Julienne and Philips. This branch of high resolution molecular spectroscopy has made significant progress in the past few years and this article will be a good starting point for a newcomer in the field.

With the recent development of zero-kinetic energy (ZEKE) photoelectron spectroscopy as well as resonance enhanced multiphoton ionization (REMPI) sub-wavelength resolution in photoelectron spectroscopy are routinely achievable and there have been numerous reports of rotationally resolved photoelectron spectra of light molecules. Wang and McKoy review the theoretical framework to understand the experimental results. Central to the understanding of the rich dynamics of rotational quantum state specific studies of molecular photoionization are a number of dynamical issues such as strong *l*-mixing in the molecular photoelectron continua, parity selection rules, partial wave mixing and interference. The article also reviews the experimental results of the rotationally resolved PES of a number of small molecules.

The infrared reflections absorption spectroscopy (IRRAS) technique is now no longer restricted to the study of well defined surfaces and more complex systems are being studied by this technique. IRRAS has been applied to investigate monolayers formation at the air-water interface. Mendelsohn, Brauner and Gericke review both the experimental and theoretical status of the field. Based on their survey the authors predict that the time is ripe for additional application of IRRAS especially to biological problems – interfacial enzyme catalysis, pulmonary surfactant functions, etc.

While experimental surface chemistry is moving towards an era where more complex systems are being studied, theoretical models still have a long way to go. While there are numerous reports on theoretical and computational investigations of adsorption of small molecules on well-defined surfaces, concomitant studies on the reactions of these adsorbed molecules have been few and far apart. This is partly because microscopic simulations, classical molecu-

lar dynamics or quantum scattering, require accurate potential energy surfaces. Garrison and Srivastava have reviewed the various recipes for generating many body reactive potential energy surfaces as well as their application. The potential energy surfaces described are for specific systems, the group IV elements and metals. The authors conclude by emphasizing the need for the development of new functional forms for multicomponent reactive systems.

Nuclear magnetic resonance continues to be an exciting technique for structure elucidation especially of biomolecules. In the last few years, an almost bewildering array of sophisticated new pulse experiments have been developed. Pelton and Wemmer describe the development of heteronuclear pulse sequencing experiments wherein the chemical shift of a proton is correlated with heteronuclear (^{15}N , ^{13}C or ^{31}P) chemical shifts. The technique has allowed investigation of protein and nucleic acid structures in the 10–40 kDa range in contrast to homonuclear ^1H methods which are limited to systems less than 10 kDa in size. Coulombic interactions and salt effects in nucleic acid solutions have been described in an article by Anderson and Thomas Record, Jr.

Nanochemistry is an emerging discipline within physical chemistry. Primary interest has focussed on the novel electronic structure and reactivity properties of small particles. Recent advances in the preparation and characterization of nanocrystals have also helped in addressing one of the long-standing questions of how large a system should be before it can exhibit a true thermodynamic phase transition. Any explanation or investigation would have to eliminate or establish the role of surface energy of these particles. The article on high pressure structural transformations in CdSe, CdS and Si nanocrystals by Tolbert and Alivisatos is quite timely. They review the experimental situation on solid-solid structural transformations in particles with different sizes and conclude that the observed elevation in the structural transition pressure is kinetic rather than a thermodynamic phenomenon.

In an excellent article, Yang and Parr describe various new developments in the density functional theory for calculating electronic structure of molecules. The goal of the article is set out clearly in the introduction. Recent contributions

to the basic theory, extension of the applicability to very large molecules and the understanding of chemical reactivity have been considered for discussion. This article is timely since this field is seeing a tremendous recent surge in popularity among chemists. The accuracy achievable currently using this method has been compared with that of conventional quantum chemical calculations for computing ground states.

Nucleation plays a key role in many natural phenomena, from crystallization in melts to particle formation in stratospheric clouds. It is not surprising that the study of homogenous and heterogenous nucleation is an old subject. Recent developments in both theory and experiment have given rise to a resurgence of interest in nucleation. Experimentalists, today, can measure actual nucleation rates from 10^{-4} to $10^5 \text{ cm}^{-3} \text{ s}^{-1}$ as well as probe the molecular content of these nucleating clusters using a variety of techniques. Experiments have gone hand-in-hand with progress in large-scale molecular dynamics simulation of the nucleation process. These developments have now made it possible to simulate both by experiment and computation, many of the particle formation phenomena occurring in the atmosphere. The article by Laaksonen, Talnaker and Oxtoby reviews all aspects of nucleation, experiment, theory and applications and provides a reasonable introduction to the subject for the non-initiate.

Finally, we have one criticism about the organization of this volume. No particular format has been followed by the authors while writing the reviews. As a result while some articles give a broad perspective of a field, others are narrow and limited in scope. All articles, however, carry important references in the field for the readers. This volume of *Annual Review of Physical Chemistry* certainly covers current topics and will be a useful addition to all libraries and groups working in the area of physical chemistry/chemical physics.

Oxidative Stress and Aging. R. G. Cutler, L. Packer, J. Bertram and A. Mori, eds. Birkhauser Verlag, P. B. No. 133, CH-4010, Basel, Switzerland. 1995. 396 pp. Price: US\$ 124.

I am never keen on reading a book on proceedings of a symposium or contributing an article for one such. I feel that the material therein is old, repetitive and sketchy. In most cases they reflect the author's viewpoint and in some cases a way of bypassing the stranglehold of difficult peers. The authors would be delighted to give the invited talks and participate in the discussions, but to provide a written text is another matter. It is a task for the editors to collect the articles in time. The present book had proved these beliefs wrong. The first international conference on oxidative stress and aging was held in Hawaii, USA in 1994 and this book published in the next year reflects its deliberations. The editors say that they had to select some articles out of many more received. The subject was covered well, the articles are uniformly informative and current. The most useful item in the book is the list of references including the titles, mostly from the last 10 years indicative of the novelty and burst of activity of the field.

The 35 articles are grouped in related areas under the following titles:

oxidative stress and cellular senescence, genetic stability and damage, DNA repair genetics and life span, protein and lipid oxidation, mitochondria, age-related diseases and cancer, neuro-degeneration, nutrition, nitric oxide. Two introductory articles by two of the editors gave a preview of the two parts, oxidative stress and aging. These are recommended for study to get an idea of the status of this field of study. The articles covered too many subjects such as apoptosis, vascular smooth muscle cell proliferation, DNA damage and repair, poly ADP-ribose polymerase, muscle damage, diabetes, carcinogenesis, Parkinson's disease, dietary antioxidants and reactive oxygen species including nitric oxide. The articles provide frontier information on the current research activities focussing on the free radical theory of aging. The recent findings would have found a place in one or the other article. Thus I believe this book will be of value for the workers in the field and those who want to be initiated.

I have noticed band-wagon spirit had set in already. Beliefs are overtaking experiments and form the basis of theories, mostly correct albeit some unproven. Some examples are NAD-depletion cause of cell death, superoxide radical 'damaging in itself', 'most destructive process initiated by hydroxyl radicals is lipid peroxidation', 'longevity determi-

nant processes', importance of cellular GSH and vitamin E as antioxidants, cellular damage of macromolecules inevitable, SOD, catalase and glutathione oxidase are antioxidant enzymes, life-span proportional by their cellular concentration (given on cover illustration), contradictory reports on anti-cancer effect β -carotene, dietary restriction prolongs life, tea-polyphenols powerful antioxidants.

On such articles and books, I look for illustrations that unify information from many publications, catch the eye and leave a strong impression. In this I was disappointed. Some of these, eg. pages 31 and 102, do not convey the message and the one before the preface page lists all the 'actors' but not the 'action'. The block on 'hydrogen peroxide removal' on page 3 has unbalanced equations - H_2O could have been shown as a product for glutathione peroxidase and O_2 should not have been shown as a substrate for catalase. I also found that summaries are printed in a very small print almost unreadable. Notwithstanding these, I recommend this book to those workers interested in the field of oxidant stress.

The cakravāla method

S. Raghavan

The object of this article spurred by a book review in *Current Science* (1996, 70, 753–754) is to try to place in proper perspective the well-known work of Indian mathematicians especially their kuttaka, bhāvanā and cakravāla methods evolved in connection with the solution in integers of certain indeterminate equations of degree one or two. In this effort, we base ourselves completely on André Weil's masterly, unbiased and incisive analysis of this topic in his beautiful book *Number Theory – An Approach Through History – From Hammurapi to Legendre*¹. Any help needed to understand related results concerning continued fractions can be readily secured from the book *An Introduction to the Theory of Numbers*² (especially chapter 7), although we endeavour to skirt a reference thereto by the reader by providing as self-contained an account as possible of facts related to simple continued fractions (in the sequel).

Solving indeterminate equations of the first degree, say $ax + by + cz + \dots = m$ in the variables x, y, z, \dots with integral coefficients a, b, c, \dots for integer values of the variables has been the key to cracking puzzles or finding integral solutions of simultaneous simple linear congruences, e.g. $x \equiv k \pmod{r}$, $y \equiv l \pmod{s}$ requiring $x - k, y - l$ to be divisible by integers r, s respectively for given integers k, l . A single linear congruence $px \equiv m \pmod{q}$ in the variable x for the modulus q is equivalent to a linear equation $px - qy = m$ in two variables x, y . Euclid's algorithm for finding the greatest common divisor of the integers p and q provides a method of solving the last-mentioned equation; expanding the rational number p/q (for $q \neq 0$) as a simple continued fraction gives an alternative (but equivalent) approach to the same problem. A clear description of the general solution of this linear equation in x, y can be found in the Sanskrit text *Aryabhatīya* of the 5th or 6th century A.D. In subsequent Sanskrit treatises, this method came to be known as the 'kuttaka' (= 'pulveriser') and is indeed a kind of forerunner of

Fermat's powerful principle of 'infinite descent'. It is also the 'first ever explicit description' of the general solution from anywhere, not taking into account China. Indian astronomy at that time was under the influence of Greek sources and yet perhaps one cannot with certainty attribute 'kuttaka' to Greek mathematics. In utter disregard or (possible) ignorance of this Indian dimension to the 'kuttaka' and of the connection with the seventh book of Euclid's *Elementa*, Bachet inserted a strong claim to the method as his own, in the second edition of his book on *Problèmes plaisants et délectables*.

Let N be a natural number which is not the square of an integer; the simplest example is $N = 2$. In view of the connection with finding close approximations to the irrational number \sqrt{N} by rational numbers, indeterminate equations of degree 2 like $x^2 - Ny^2 = \pm m$ for given integers m must have been indeed investigated by the Greek mathematicians. Special cases of the 'composition formulae'

$$(x^2 - Ny^2)(z^2 - Nt^2) = (xz \pm Nyt)^2 - N(xt \pm yz)^2, \quad (1)$$

e.g. for $N = 3, z = 5, t = 3$ may have been applied by Archimedes for finding rational approximations to $\sqrt{3}$. However, the composition formula (1) occurs explicitly in the work of Brahmagupta (in the 7th century) while seeking the solution in integers x, y of equations of the form $x^2 - Ny^2 = \pm m$ for any fixed natural number m . For $m = 1$, the name Pell's equation has come to stay for the diophantine equation

$$x^2 - Ny^2 = 1. \quad (2)$$

Such equations 'do occur in Diophantus...', but it is a rational solution that is asked for, even when accidentally a solution in integers is obtained...'. It may be reasonable to suppose that Archimedes was interested in equations of this type or, to be very optimistic, that he had even found a general method of solving equations like (2).

In the book entitled *Algebra with Arithmetic and Mensuration, from the Sanscrit of Brahmagupta and Bhāscara* by H. T. Colebrooke, one finds an entire section dealing with Brahmagupta's investigations (in the seventh century) on Vargaprakṛti – the solution of equations $Ny^2 + m = x^2$ in integers x, y with N as above and m , a non-zero integer; N is called 'gunaka' (or 'prakṛti') and m the ksepa (= additive). If the triple $(x, y; m)$ stands for a solution in integers x, y of the equation $x^2 - Ny^2 = m$, keeping N fixed all the while, the composition formula (1) is given by Brahmagupta in the form

$$(x, y; m) \cdot (z, t; n) \rightarrow (xz \pm Nyt, xt \pm yz; mn).$$

These laws acquired, in the post-Brahmagupta manuscripts in India, the name bhāvanā ('production') rules; in modern parlance, this is just the 'multiplicativity of the norm'. Brahmagupta shows, how composition of $(x, y; m)$ with a triple $(p, q; 1)$ gives a triple $(x', y'; m)$ for the same additive m . Under composition with itself, any triple $(x, y; m)$ yields a solution in rational numbers $x'/m, y'/m$ of the equation $(x'/m)^2 - N(y'/m)^2 = 1$ and indeed a triple $(x'/m, y'/m; 1)$ if x'/m and y'/m are actually integers. Applying then his bhāvanā, Brahmagupta solves equation (2) for several cases of N including ones like $N = 92$ or $N = 83$. For $m = -1$ or ± 2 , composition of a triple $(p, q; m)$ with itself leads to $(p^2 + Nq^2, 2pq; 1)$ or $((p^2 + Nq^2)/2, pq; 1)$ respectively.

Despite the remarkable results of Brahmagupta, the general solution of (2) is still not at hand. Actually, the cakravāla ('cyclic' method) for getting the general solution of equation (2) is to be found much later, around the twelfth century, in the work of Bhāskara; nearly the same description of the cakravāla is provided in a commentary of the eleventh century by 'an otherwise unknown author' Jayadeva, leaving one to guess who was the true inventor of the cakravāla. Following Weil, we can see how the brilliant cakravāla arises in a

natural manner from the work of earlier Indian mathematicians.

Starting from a triple (p_0, q_0, m_0) with 'small' m_0 , the idea is to use the bhāvanā to get a triple (p_1, q_1, m_1) with m_1 also 'small' and eventually hope to hit upon a triple $(u, v, 1)$ giving a non-trivial solution of equation (2), of course. First we can assume, without loss of generality that the greatest common divisor d of p_0 and q_0 in the initial triple is already equal to 1, since if $d > 1$, we could start instead from $(p_0/d, q_0/d, m_0/d^2)$. Since p_0 and q_0 have greatest common divisor 1, so have q_0 and m_0 clearly. Then the kuttaka readily enables us to find an integer x_0 such that m_0 divides $p_0 + q_0x_0$ (i.e. solve the arithmetical congruence $q_0x_0 \equiv -p_0 \pmod{m_0}$). If, in addition, the chosen x_0 is fixed in its residue class modulo m_0 so as to satisfy the inequalities $x_0 < \sqrt{N} < x_0 + m_0$, then we see that $\sqrt{N} + x_0$ cannot be negative provided that $|m_0| < 2\sqrt{N}$ (since ' $\sqrt{N} + x_0 < 0$ ' would imply that $2\sqrt{N} < \sqrt{N} + x_0 + |m_0| < |m_0|$) and consequently for $|m_0| < 2\sqrt{N}$,

$$0 < N - x_0^2 = (\sqrt{N} - x_0)(\sqrt{N} + x_0) < |m_0|(\sqrt{N} + \sqrt{N}) = 2|m_0|\sqrt{N}. \quad (3)$$

Composition of (p_0, q_0, m_0) with $(x_0, 1, x_0^2 - N)$ gives rise to the triple (p_1, q_1, m_1) where

$$\begin{aligned} p_1 &:= (p_0x_0 + Nq_0)/m_0, \\ q_1 &:= (p_0 + q_0x_0)/m_0, \\ m_1 &:= (x_0^2 - N)/m_0 \end{aligned} \quad (4)$$

are clearly integers. (In fact, by composition, $(m_0p_1)^2 - N(m_0q_1)^2 = m_0(x_0^2 - N) = m_0^2m_1$ and $q_0^2(x_0^2 - N) = q_0^2x_0^2 - p_0^2 + m_0 = m_0((q_0x_0 - p_0)(q_0x_0 + p_0)/m_0 + 1)$ is divisible by m_0 , i.e. $x_0^2 - N$ is divisible by m_0 in view of the greatest common divisor of m_0 and q_0^2 being 1 by our assumption above. Thus m_1 is an integer while the congruence condition on x_0 implies that q_1 is an integer as well and so are $p_1^2 = Nq_1^2 + m_1$ and p_1 too as a consequence!) Moreover, $|m_0m_1| = N - x_0^2 < 2|m_0|\sqrt{N}$, by (3) and therefore we have

$$|m_1| < 2\sqrt{N}. \quad (5)$$

Starting with the triple (p_0, q_0, m_0) , the passage to (p_1, q_1, m_1) as above gives an inductive construction of the triples (p_i, q_i, m_i) as follows.

It is convenient to take $q_0 = 1$ and $P_0 := [\sqrt{N}]$, the largest integer not exceeding the (positive) square root $[\sqrt{N}]$ of N , so that $0 < \sqrt{N} - p_0 < 1$. The congruence condition on x_0 now looks simpler, viz. $x_0 \equiv -p_0 \pmod{m_0}$ with $m_0 := p_0^2 - N < 0$, i.e. x_0 is any integer such that $x_0 + p_0$ is divisible by m_0 (but subject to the additional conditions $x_0 < \sqrt{N} < x_0 + |m_0|$, of course!). Due to the special choice of q_0 , the kuttaka does not need to be invoked here (for solving a congruence for x_0) but also at every subsequent step under the induction, as nicely emphasized by Weil. We reproduce his comments in this regard verbatim¹. 'Strangely enough, this does not seem to have been noticed by any of our Indian authors (nor even by their later commentators, down to the sixteenth century); they make no mention of it, and invariably refer to the kuttaka for the choice of x , even though their abundant numerical evidence could easily have convinced them that this was unnecessary.'

Let us assume the triples (p_j, q_j, m_j) , x_j for $0 \leq j \leq i$ constructed inductively with $|m_j| < 2\sqrt{N}$, $x_j \equiv -x_{j-1} \pmod{m_j}$ i.e. $x_j + x_{j-1}$ divisible by m_j , $x_j < \sqrt{N} < x_j + |m_j|$, $m_{-1} := 1$, $x_{-1} := p_0$ and $x_{j-1}^2 - N = m_{j-1}m_j$ for $j \geq 0$. Then composition of (p_i, q_i, m_i) with the triple $(x_i, 1, x_i^2 - N)$ leads to the definition of $p_{i+1}, q_{i+1}, m_{i+1}$, viz. $p_{i+1} := (p_ix_i + Nq_i)/m_i$, $q_{i+1} := (q_ix_i + p_i)/m_i$ and $m_{i+1} := (x_i^2 - N)/m_i$. The congruence condition on x_i above coupled with the relation $-q_ix_{i-1} + p_i = -x_{i-1}(q_{i-1}x_{i-1} + p_{i-1})/m_{i-1} + (p_{i-1}x_{i-1} + Nq_{i-1})/m_{i-1} = q_{i-1}(N - x_{i-1}^2)/m_{i-1} = -q_{i-1}m_i$ ensures that q_{i+1} is an integer. Since m_{i+1} is an integer by the same congruence condition on x_i , p_{i+1} is an integer too. The same kind of argument applied to derive the bound (5) leads to $|m_{i+1}| < 2\sqrt{N}$ and further ensures that $(-1)^j m_{j-1}$, $\sqrt{N} \pm x_i$ are all positive (and so $N - x^2 > 0$ for all i). We have thus, on hand, an infinite sequence of integers (the 'additives') m_0, m_1, m_2, \dots bounded by $2\sqrt{N}$ in absolute value. Hence infinitely many among them must coincide by Dirichlet's box principle. But, as we will see presently, much more is true, namely, (i) there exists an integer s such that $m_{j+s} = m_j$ for $j \geq 1$ and (ii) $m_j = 1$ for an integer j , leading to a solution of equation (2).

In other words, the m_i repeat themselves in a periodical fashion (actually, corresponding to the periodicity of the infinite simple continued fraction expansion for the quadratic irrationality \sqrt{N}).

Before moving on to indicate proofs for assertions (i) and (ii) above, it will be quite in order to quote some interesting observations by Weil (see ref. 1 pp. 23, 24, 94-97, 230-232) on the construction of (p_i, q_i, m_i) . 'The Indian prescription' for the choice of x_i within its congruence class modulo m_i is not quite the one described above, since their rule is 'to make $N - x_i^2$ "small" (i.e. in actual practice, as small as possible), but as the context shows, in absolute value' or in other words, to replace x_i by $y_i := x_i + |m_i|$ if $y_i^2 - N$ turns out to be less than $N - x_i^2$. 'It can be shown that this has merely the effect of abbreviating the procedure somewhat when that is the case,' but though 'numerically useful', can 'make the theoretical discussion much more cumbersome.' Moreover, the above rigorous treatment for constructing (p_i, q_i, m_i) 'may have been known to the Indians only experimentally; there is nothing to indicate whether they had proofs for them, or even for part of them'. 'In order to carry out the cakravālā, a 'starting point' which 'invariably they choose' is the triple $(p_0, 1, m_0)$ 'for which p_0^2 is the closest square to N , above or below.' Finally we are told to iterate the process only till we find an "additive" m with one of the values $\pm 1, \pm 2, \pm 4$ and then to make use of the bhāvanā, i.e. Brahmagupta's procedure for that case. Actually this is no more than a shortcut, since it can be shown that the cakravālā applied in a straightforward manner, would inevitably lead to a triple $(p, q, 1)$ as desired; while this shortcut is quite effective from the point of view of the numerical solution, it destroys the 'cyclic' character of the method, which otherwise would appear from the fact that the additives \dots would repeat themselves periodically corresponding to the periodicity of the continued fraction of \sqrt{N} .

'For the Indians, of course, the effectiveness of "cakravālā" could be no more than an experimental fact, based on their treatment of a great many special cases, some of them of considerable

HISTORICAL NOTES

complexity and involving (to their delight, no doubt) quite large numbers. Fermat was the first to perceive the need for a general proof and Lagrange the first to publish one. Nevertheless, to have developed the cakravāla and to have applied it successfully to such difficult cases as $N=61$ or $N=67$ had been no mean achievement.'

We now go on to the promised proofs for assertions (i) and (ii) above. The triples (p_i, q_i, m_i) and x_i for $i \geq 0$ as constructed above enable us to obtain an infinite simple continued fraction for \sqrt{N} . Let $\xi_0 := \sqrt{N} + p_0$, $a_0 := 2p_0$, $a_i := (-1)^i(x_{i-1} + x_{i-2})/m_{i-1}$ for $i \geq 1$ and η_j be defined by $\sqrt{N} = x_j + \eta_j$ for $j \geq 0$. Then, in view of the relation $x_{j-1}^2 - N = m_{j-1}m_j$ for $j \geq 0$, we can derive the following:

$$\begin{aligned}\xi_0 &= a_0 + \frac{1}{\xi_1} \text{ with} \\ \xi_1 &:= \frac{1}{\sqrt{N} - p_0} = \frac{\sqrt{N} + p_0}{-m_0} \\ &= \frac{x_0 + \eta_0 + p_0}{-m_0} = \frac{x_0 + x_{-1}}{-m_0} + \frac{\eta_0}{-m_0} \\ \xi_1 &= a_1 + \frac{1}{\xi_2} \text{ with } \xi_2 = -\frac{m_0}{\sqrt{N} - x_0} \\ &= -\frac{m_0(\sqrt{N} + x_0)}{-m_0 m_1} = \frac{x_1 + x_0 + \eta_1}{m_1} \\ \xi_2 &= a_2 + \frac{1}{\xi_3}, \xi_3 = \frac{m_1}{\sqrt{N} - x_1} = \frac{\sqrt{N} + x_1}{-m_2} \\ &= \frac{x_2 + \eta_2 + x_1}{-m_2} = \frac{x_1 + x_2}{-m_2} + \frac{\eta_2}{-m_2} \\ &\dots \\ \xi_i &= \frac{\sqrt{N} + x_{i-2}}{(-1)^i m_{i-1}} = a_i + \frac{1}{\xi_{i+1}} \dots \dots \dots \\ &\dots \dots \dots (7)\end{aligned}$$

Using terminology from the theory of continued fractions², we see that $\xi_0 = \sqrt{N} + [\sqrt{N}]$ has the infinite continued fraction expansion

$$\xi_0 = \langle a_0, a_1, a_2, \dots \rangle,$$

with the natural numbers a_0, a_1, a_2, \dots occurring as partial quotients.

There exists, as we shall see now, a minimal positive integer r such that $a_{i+r} = a_i$ for all i from a certain index l , say. Now $\xi_i = (\sqrt{N} + x_{i-2})/(-1)^i m_{i-1}$ as derived inductively in (7) and coupled with the bound $|m_i| < 2\sqrt{N}$ for all $i \geq 0$, the relation $x_i^2 = N + m_i m_{i+1}$ leads to the

bound $|x_i|^2 < 5N$ for all $i \geq 0$. The number of distinct pairs $(x_{i-1}, (-1)^{i-1} m_i)$ of integers for $i = 1, 2, 3, \dots$ subject to such fixed bounds (depending only on the given non-square natural number N) can only be finite. Thus there exist indices l and $k > l$ such that

$$(x_{l-1}, (-1)^{l-1} m_l) = (x_{k-1}, (-1)^{k-1} m_k), \text{ i.e.}$$

$$\begin{aligned}\xi_l &= \langle a_l, a_{l+1}, \dots, a_{k-1}, \xi_k \rangle \\ &= \xi_k = \langle a_k, a_{k+1}, \dots \rangle,\end{aligned} \quad (8)$$

and therefore

$$\begin{aligned}\xi_0 &= \langle a_0, a_1, \dots, a_{l-1}, a_l, a_{l+1}, \dots, a_{k-1}, \xi_k \rangle \\ &= \langle a_0, a_1, \dots, a_{l-1}, a_l, a_{l+1}, \dots, a_{k-1}, \\ &\quad a_l, a_{l+1}, \dots, a_{k-1}, \dots \rangle \\ &= \langle a_0, a_1, \dots, a_{l-1}, \overline{a_l, a_{l+1}, \dots, a_{k-1}} \rangle\end{aligned}$$

is a periodic continued fraction with period $r := k - l$, proving that $a_{i+r} = a_i$ for all $i \geq l$. Clearly r can be chosen to be minimal.

In the case of $\xi_0 = \sqrt{N} + [\sqrt{N}]$, we can even show that $l = 0$, i.e.

$$\xi_0 = \langle a_0, a_1, a_2, \dots, a_{r-1} \rangle \quad (9)$$

and so is 'purely periodic'. For this purpose, we note first that while $\xi_0 = p_0 + \sqrt{N} > 1$, its 'conjugate' $\xi'_0 := p_0 - \sqrt{N}$ satisfies the inequalities $-1 < \xi'_0 < 0$. Denoting for $\xi_i = (\sqrt{N} + x_{i-2})/(-1)^i m_{i-1}$ its 'conjugate' $(-\sqrt{N} + x_{i-2})/(-1)^i m_{i-1}$ by ξ'_i , we have

$$\xi_i = a_i + 1/\xi_{i+1}, \quad \xi'_i = a_i + 1/\xi'_{i+1}. \quad (10)$$

Now $a_i \geq 1$ for every i , $(-1)^i m_{i-1}$, $\sqrt{N} - x_{i-2}$ are all positive (by construction) and so, $\xi'_i < 0$, leading to $1/\xi'_{i+1} = \xi'_i - a_i < -1$, i.e. $-1 < \xi'_{i+1} < 0$ for every $i \geq -1$. But then, using (10), we have $0 < (-1/\xi'_{i+1}) - a_i < 1$ so that a_i is just the largest integer $[-1/\xi'_{i+1}]$ not exceeding the positive real number $-1/\xi'_{i+1}$. Since, for $k > l$, $\xi_k = \xi_l$ by (8), the 'conjugates' ξ'_k, ξ'_l coincide and so $a_{k-1} = a_{l-1}$. Thus from $\xi_k = \xi_l$ we conclude that $\xi_{l-1} = a_{l-1} + 1/\xi_l = a_{k-1} + 1/\xi_k = \xi_{k-1}$. Iteration yields $\xi_r = \xi_{k-l} = \xi_0$, proving (9).

Now for any $j \geq 1$, ξ_{jr} has the same continued fraction expansion

$$\begin{aligned}\langle a_0, a_1, a_2, \dots, a_{r-1}, a_0, a_1, a_2, \dots, a_{r-1}, \dots \rangle \\ = \langle a_0, a_1, a_2, \dots, a_{r-1} \rangle\end{aligned}$$

as ξ_0 . Hence

$$\frac{\sqrt{N} + x_{jr-2}}{(-1)^{jr} m_{jr-1}} = \xi_{jr} = \xi_0 = \sqrt{N} + p_0,$$

$\sqrt{N} (1 - (-1)^{jr} m_{jr-1}) = (-1)^{jr} m_{jr-1} p_0 - x_{jr-2}$. But if $c + d\sqrt{N} = 0$ for integers c, d , then necessarily $c = d = 0$. Hence, in particular,

$$(-1)^{jr} m_{jr-1} = 1.$$

Whenever jr is even (e.g. $j = 2$ for odd r and $j = 1$ for even integers r), we have $m_{jr-1} = 1$ and the triple $(p_{jr-1}, q_{jr-1}; 1)$ gives a solution of the diophantine equation (2) proving assertion (ii). Assertion (i) also follows from above easily.

An example of how unsparing a critical analysis can tend to be (when intended or called for) may be found in Weil's remarks on Euler's contribution to the topic of 'Pell's equation' and the related continued fraction algorithm, on pages 232-233 (ref. 1): 'while Euler drew attention' to the periodicity and 'palindromic' property of the partial quotients a_i in the 'continued fractions for square roots \sqrt{N} , as well as to their use in solving Pell's equation, there is no sign that he (Euler) ever sought to back up his findings by anything more than experimental evidence. He (Euler) did mention that the values obtained by his process for the integers B_i, A_i, m_i are necessarily bounded...; from this he (Euler) could at least have derived the conclusion that the sequence (m_i) is periodic from a certain point onwards, but he failed to mention this, or did not bother to do so'. When in his later years (after Lagrange gave a 'definitive treatment' of the subject, based on the continued fraction algorithm...), 'Euler came back to the topic of Pell's equation, he added nothing of substance to what by that time was already public knowledge on that subject'.

Fermat must have been in the dark about the contribution of the Indian mathematicians to the solution of (2) and also possibly about Archimedes' *Problema bovinum*. He offered (in 1657) the problem of solving equation (2) (in integers, of course!) as a challenge to the English mathematicians and all others. In a personal letter to Huygens, a few months later, commenting on the solution by Wallis and Brouncker, he observed that 'the English had failed to give a general proof'; such a ('general') proof, according to Fermat, could only be 'obtained by descent'. But perhaps 'Fermat's method of solution (for (2)) did not greatly differ

from the one he got from Wallis and Brouncker' and 'he had been able to extract from it a formal proof of the fact that it always leads to a solution'. The method 'which Wallis credits to Brouncker' is 'equivalent to the Indian cakravāla method as well as to the mod-

ern treatments based on continued fraction'.

Addendum

Fifty years of the exact solution of the two-dimensional Ising model by Onsager

Somendra M. Bhattacharjee and
Avinash Khare

[*Curr. Sci.*, 1995, **69**, 816–821]

We would like to make the following corrections/additions which we learnt after the paper was written.

W. Lenz was working in Rostock University (not Rostalk as mentioned in the text).

E. Ising was a teacher (and later became the headmaster) of a Jewish school in Germany from 1934 to November 1938. When his school was damaged, he managed to leave Germany. It was as late as 1949 that he realized that his name had become famous.

It seems that Ising also agrees that the model should be named the Lenz–Ising model. The name 'Ising model' became popular following the title of Peierls' paper¹².

It appears that Heisenberg in his 1928 paper⁸ also thought that at least eight nearest neighbours are needed for a phase transition. We are not sure whether this comment by Heisenberg refers to the Ising model or to the new model he proposed in that paper.

We thank Prof. Sigismund Kobe of University of Dresden for several clarification.

MEETINGS/SYMPOSIA/SEMINARS

COAL-96 International Symposium on Coal: Science, Technology, Industry, Business and Environment

Date: 18-19 November 1996

Place: Dhanbad

The symposium is being organized to commemorate the Golden Jubilee of Central Fuel Research Institute. Topics include: Coal science, Advanced coal preparation, Advanced coal utilization, Coal chemicals.

Contact: Dr Kotur S. Narasimhan
Director, CFRI & Secretary
National Steering Committee
Central Fuel Research Institute
P.O. FRI
Dhanbad 828 108, India
Phone: 0326-461840, 461710, 460019
Fax: 0326-91-326-464350

1996 Asia-Pacific Microwave Conference — APMC '96

Date: 17-20 December 1996

Place: New Delhi

Topics include: Any paper concerned with the utilization and application of microwave theory will be considered.

Contact: Dr R. S. Gupta
Conference Secretary APMC '96
Department of Electronic Science
University of Delhi South Campus
New Delhi 110 021, India
Phone: 91-11-601955, 91-11-602440
Fax: 91-11-6886427

DAE Solid State Physics Symposium

Date: 27-31 December 1996

Place: Mumbai

Topics include: Phonon physics; Electron states and electronic properties; Magnetism and magnetic properties; Semiconductor physics; Physics of defects and disordered materials; Transport properties; Superconductivity and superfluidity; Liquids, liquid crystals and plastic crystals; Phase transitions and critical phenomena; Surface and interface physics; Non-equilibrium phenomena in solids; Physics of complex systems; Resonance studies and relaxation phenomena; Solid state devices, techniques and instrumentation.

Contact: Dr M. Ramanadham
Convener, DAE SSPS96
Solid State Physics Division
Bhabha Atomic Research Centre
Trombay, Mumbai 400 085, India
Phone: 22-5563060; 5563120

E-mail: ssps@magnum.barc.ernet.in.

International Seminar on Quaternary Sea-level Variation, Shoreline Displacement and Coastal Environment

Date: 20-26 January 1997

Place: Thanjavur

Topics include: Inter-glacial sea levels and coastal environmental changes; The record of sea-level changes on continental shelves; Coral reefs and sea-level change; Sediment sources and sinks in coastal zones, particularly sand dunes and estuaries during the Holocene; Coastal changes associated with seismic events; Storm signatures and El Nino events and their impacts on coasts; Exploration, development, refinement and application of new techniques to elucidate the understanding of coastal dynamics.

Contact: Prof. G. Victor Rajamanickam
Convenor, International Seminar
Department of Earth Sciences
Tamil University
Thanjavur 613 005, India
Phone: 0091-04362-73219, 73302
Fax: 0091-04362-40040, 40193

4th National Seminar on Physics and Technology of Sensors

Date: 3-5 February 1997

Place: Vallabh Vidyanagar

Topics include: Sensor fundamentals and physics; Sensor materials and their processing; Fabrication techniques; Micromachining and integral sensors; Sensor technology; System and applications; Chemical sensors; Gas and pollution related sensors; Mass sensitive devices; Intelligent smart systems; Industrially important sensors; Agro-based sensors, Automobile sensors, Bio-sensors and biomedical sensors; Interface electronics; Physical sensors: Thermal, magnetic, CNC sensors; Optical fibre-based sensors.

E-mail: root @ patel, ernet.in

3rd International Symposium on Innovations in Pharmaceutical Sciences & Technology

Date: 7-9 February 1997

Place: Ahmedabad

Programme summary: I. Plenary and invited lectures (Pharmaceutical technology and novel drug delivery systems, Drug discovery and design, Pharmacokinetics, drug metabolism and clinical pharmacology and Traditional medicine and medicinal plant products). II. Pre-symposium workshops on Oral Controlled Drug Delivery and Drug Discovery – Chemical Approaches. III. Poster

presentations.

National Conference on Spectrophysics (NCONS 97)

Date: 10-12 February 1997
Place: Chennai

Topics include: Raman spectroscopy; Infrared spectroscopy; Vibrational analysis and molecular structure; Band shapes, dynamics; Band intensities; Macromolecules and Biological systems; Surface and Interfacial phenomenon, SERS; Inorganic materials, matrices; Semiconductors and semiconductor micro structures; Superconductors; Phase transitions; Effects of temperature and pressure; Industrial and medical applications; Pollution analysis; New techniques; Characterization of crystalline & ceramic compounds; Nuclear spectroscopy; Hyperfine structure studies; Laser and laser-based spectroscopy.

Contact: Dr S. Gunasekaran
Convenor, NCONS 97
Post Graduate and Research Department of Physics,
Pachaiyappa's College
Chennai 600 030, India

Seminar on Herbal and Microbial Pesticides

Date: 14-16 February 1997
Place: Varanasi

Technical sessions include: 1. Old traditional and indigenous pesticides, 2. Herbal pesticides, 3. Microbial pesticides.

Contact: Dr N. K. Dubey
Organizing Secretary
Department of Botany, Banaras Hindu University
Varanasi 221 005, India

Training Course in Palaeoseismology

Date: 28 March-6 April 1997
Place: Dehra Dun

A training course is being organized for young scientists/ research workers actively involved in studies on seismology, seismotectonics, active tectonics, seismic hazard zonation and related fields involving extensive theory and field work including study of trenches for palaeoseismology. The faculty will include experts from USA, Japan and India.

Grams: Erthsiens, Thiruvananthapuram

GOVERNMENT OF INDIA

DEPARTMENT OF SCIENCE & TECHNOLOGY

Programme on Nonlinear Phenomena, Complex Matter and Biologically Inspired Physics

The importance of nonlinear science, soft condensed matter (such as colloids, powders, polymers and membranes) and biologically inspired physics has emerged very clearly in recent years. In view of this and given the large mutual overlaps of these disciplines as well as their interdisciplinary nature, the DST has considered it fit to constitute a separate Programme Advisory Committee (PAC) specifically to foster research in these areas. Suitable project proposals are invited in the above general fields.

Research proposals should pay particular attention to the development and application of ideas and techniques that cut across disciplines and/or seek to elucidate and provide insight into the general paradigms of complexity and nonlinearity.

Proposals that come under this general purview include:

Dynamical phenomena far from equilibrium, driven systems, chaos, especially spatiotemporal. This encompasses both model systems such as sandpiles and driven lattice gases as well as 'real' examples such as colloids in shear flow and sedimentation, turbulence, kinetics of phase ordering, granular matter (powders), earthquakes, pattern formation, etc.

Physics of soft condensed matter. Membranes (biological and model), Langmuir monolayers and Langmuir-Blodgett films, micelles, vesicles, lamellar structures, microemulsions, emulsions, foams, and other structures in surfactant solutions: liquid crystals, both thermotropic and lyotropic, polymer solutions, gels, and melts: colloidal suspensions, including ferrofluids, electro-rheological fluids, etc.

Biologically inspired physics. Models in evolutionary biology and population genetics, evolution of complexity, neural networks, optimization, protein folding, motor proteins and molecular ratchets, etc.

Qualified researchers interested in submitting project proposals to be considered for funding may write to the following address for further details:

Current Science, founded in 1932, is published by the Current Science Association in collaboration with the Indian Academy of Sciences. The journal is also intended as a medium for communication and discussion of important issues that concern science and scientific activity. All articles published in *Current Science*, especially editorials, opinions and commentaries, letters and book reviews, are deemed to reflect the individual views of the authors and not the official points of view, either of the Current Science Association or of the Indian Academy of Sciences.

INFORMATION FOR CONTRIBUTORS

GENERAL

All manuscripts should be addressed to the Editor, *Current Science*, P. B. No. 8001, C. V. Raman Avenue, Bangalore 560 080. Submission of an article will be held to imply that it has not been previously published and is not under consideration for publication elsewhere; and further, that if accepted, it will not be published elsewhere. *Three copies of contributions of all categories* are required, with a letter of transmittal giving (i) names and complete addresses of the authors and (ii) title of the contribution and the category in which it is submitted (see below).

Current Science is a multidisciplinary journal and therefore research and review papers of general significance that are written clearly and well organized will be given preference. All papers will be first assessed by a Reviewing Editor. Papers found unsuitable in terms of the overall requirements of the journal will be returned to the authors. The others will be sent for detailed review. *Both solicited and unsolicited material will be reviewed.* Authors of these papers will be notified of acceptance, rejection, or need for revision of the paper. Returned papers cannot be resubmitted. Illustrations and other material to be reproduced from other publications must be properly credited; it is the authors' responsibility to obtain permission for reproduction (copies of letters of permission should be sent).

CATEGORIES OF MANUSCRIPT

General articles (not exceeding 5000 words) discuss current trends in research in a field that will be of interest to readers outside the field; interdisciplinary topics: science policy and administration; or some aspect of the application of science and technology to human needs or the impact of science and technology on society/ecosystems/life. They should include a summary not exceeding 100 words, introductory paragraph(s), brief subheads at appropriate places to point to what follows, illustrations that will help a general reader, and references.

Review articles (not exceeding 5000 words) are expected to survey and discuss recent developments in a field. They should be well focused and organized, and avoid a general, 'textbook' style.

Research articles (not exceeding 4000 words) should report research results of fairly major significance. They should include an abstract not exceeding 100 words, introductory paragraph(s), and brief subheads.

Research communications (not exceeding 2000 words) should contain important findings that are novel and of fairly broad interest. They should include a brief abstract and an introductory paragraph. Text should not be broken up under subheads.

Correspondence includes letters, not exceeding 500 words, that are of general interest to scientists. All letters cannot be published.

Scientific correspondence contains technical comments, including those on articles or communications published in *Current Science* within the previous six months. Letters may be reviewed and edited.

Research news articles are intended to inform nonspecialists about recently published advances or important findings discussed at a meeting. Authors should also send a copy of the paper(s) on which the article is based. Meeting reports should avoid merely listing brief accounts of topics discussed, and must convey to readers the significance of an important advance.

Research accounts articles are intended to be personalized reviews of research from the authors' own laboratory, based on a body of published work. The articles must provide appropriate background to the area in a concise introduction, which should also serve to place the author's work in proper perspective. Articles will normally

not exceed 8 to 10 printed pages.

Opinion articles present views on issues related to science and scientific activity. **Commentary** articles should contain expository notes on issues related to science and scientific activity.

Book reviews. Unsolicited reviews will also be considered. Reviews that merely 'list' brief descriptions of the contents cannot be published. Reviews should have 'context' and convey some information about the subject of the book.

Historical commentary and notes inform readers about interesting aspects of personalities or institutions of science or about watershed events in the history/development of science; most are expected to relate to India. Illustrations are welcome. Brief items will also be considered.

MANUSCRIPT PREPARATION

Manuscripts should be typed double-spaced on one side of white bond paper (21×28 cm). The pages should be numbered consecutively, starting with the title page and through the text, reference list, tables and figure legends. The title should be brief, specific and amenable to indexing. Not more than five **keywords** should be indicated separately; these should be chosen carefully and must not be phrases of several words. **Summary** and **abstract** should not have more than 100 words and should convey the main point of the paper, outline the results and conclusions, and explain the significance of the results.

Text. All papers should have a brief introduction. The text should be intelligible to readers in different disciplines and technical terms should be defined. Tables and figures should be referred to in numerical order. All **symbols** and **abbreviations** must be defined, and used only when absolutely necessary. Superscripts and subscripts and ambiguous characters should be clearly indicated. **Units of measure** should be metric or, preferably, SI. Methods should, as far as possible, be described briefly in appropriate table and figure legends.

Figures. In the case of line drawings one set of originals (without any lettering) is sufficient, with two copies containing lettering. In the case of photographs good prints are required with each copy of the manuscript; photocopies are not acceptable. Line drawings should be roughly twice the final printed size. The correct orientation should be indicated if not clear.

Photomicrographs and other photographs that require it must have a scale bar, which should be defined clearly in the legend. Primary data should be submitted as far as possible (e.g. actual photographs of electrophoretic gels rather than idealized diagrams).

References should be numbered in the order in which they appear, first through the text and then through table and figure legends. The following are examples of ways of writing references.

1. Mukundan, T. and Kishore, K., *Curr. Sci.*, 1991, **60**, 355–362.
2. Constantine, G., in *Biology of Bats* (ed. Wimsatt, W. A), Academic Press, New York. 1970. vol 1, pp. 319–322.

Acknowledgements should be brief. Footnotes are not allowed except to identify the corresponding author if not the first.

Cover photographs. Good photographs (colour or black and white) that pertain to a submitted paper will be considered for use on the cover. Good *prints* and a legend should be submitted with the manuscript. In the case of a colour picture, a transparency will be required for printing if accepted.

PROOFS AND PUBLICATION

Two sets of galley proofs are sent to the corresponding author. A reprint order form accompanies the proofs.

Weather forecasting

The evolution of meteorology in general and weather forecasting in particular to its present status as an objective scientific discipline has been a fascinating and tortuous journey. The use of complex mathematical models for dynamics of weather and climate, and their numerical integration occupies the central place in today's science of weather and climate prediction. This numerical weather (or climate) prediction, however, requires involvement of a number of seemingly unconnected disciplines. The progress made in the last few decades would not have been possible but for developments in physical and mathematical modelling, numerical methods, high performance computing and visualization, data management and analysis techniques and observing systems. In this issue Hunt (**page 520**) provides a succinct and captivating account of the current status, problems and future directions of the science of weather and climate prediction. The article provides a non-technical and encompassing survey of various methods currently in use for prediction and those which hold promise, such as expert systems, hybrid methods (man-machine mix) and neural networks. The article also provides a lucid account of emerging concepts and various problems that make the science of weather and climate prediction an exciting scientific challenge.

P. Goswami

Lichens of the Nanda Devi Biosphere Reserve

More often seen as grayish-greenish patches on tree-trunks, on stone walls of old buildings, or even on bare rocks, the lichen seem to be

one of the least glamorous (and therefore most neglected) group of living organisms. However, they are one of most widespread group of plants, with many unique and fascinating characteristics.

A lichen is in some sense a single (but symbiotic) organism, made up of two distinct partners – who by themselves are capable of leading an independent life; the dominant partner is a fungus and the subordinate, photosynthetic partner is an alga (though sometimes cyanobacteria take its place). Lichen can survive (as far as their natural history is concerned, on a global scale) in extremely inhospitable habitats and climates – from high latitudes (close to the poles) to hot, dry deserts. Paradoxically, at a local scale, they are very susceptible to adverse environmental conditions such as pollution, since they readily absorb pollutants dissolved in rainwater and dew. In fact, they are extensively used as bioindicators of pollution – including that caused by radioactive fallouts. Lichens grow very slowly – 10 to 25 millimeters in 100 years is the rate quoted in alpine and arctic regions. They are also very long-lived, surviving for more than a thousand years. In fact, the age of a specimen from Swedish Lapland has been estimated to be around of 9000 years old, making it one of the oldest living organisms.

About 25000 species of lichens have been described from all over the world. However, this is one of the least actively studied groups. An authoritative text-book published in 1967 estimated that it would take about 20 years for lichen to be as well described as fungi – and the 1983 edition of the same book has discreetly changed the phrase '20 years' to 'many years'.

From India, studies on nearly

2000 species of lichen and almost 700 species of macrolichen have been reported, mostly dealing with taxonomic aspects. One of the first investigations focusing on the community ecology of lichens is reported on **page 568** of this issue by Hans Raj Negi and Madhav Gadgil. Covering the altitudinal range from 2100 meters to 4500 meters in the western part of the Nanda Devi Biosphere Reserve, and a diversity of habitats ranging from roadside grass and scrub to pine forests and alpine meadows, the authors have recorded 76 species of macro-lichens from 16 transects (each 50 m × 10 m).

Unfortunately, just like the more high profile mammal and bird species, the lowly lichens too appear to be under threat from human interference such as deforestation. More perceptively, the authors have identified a more subtle threat from the overgrowing weeds. These weeds, which rapidly deplete nutrients from the soils, have become more common due to a ban on grazing in the meadows – ironically introduced for protecting the biodiversity in the meadows! The authors also point out how the lichens, due to their essential oils and nitrogen-fixing capabilities, could play an important economic role in that region.

'Mariner' element

Getting a free ride is second nature to humans, but this trait is often combined with good sense. On a Kanpur-Jhansi train journey some years ago, I asked my neighbour why, without reservations or even tickets, he and his fifty odd friends had entered a reserved compartment and made themselves com-

fortable. He looked with pity at my stupidity and replied that the reserved compartments were the only ones with space for them. Transposable elements are like humans taking a free trip. These elements, bits of DNA present in an organism can often hop around the host's chromosomes, often 'unnoticed' but sometimes causing serious trouble. Are these elements parasites? Where did they come from, how many of them can an organism tolerate? While many biologists delve into these basic questions, others have used transposable elements as tools for introducing foreign DNA into organism. Transposable elements have characteristic sequences at each of their termini which are required for integration and mobility in the host genome. In addition, these elements encode protein products, 'transposase' that are required for effecting their movement in the host's genome. In a major breakthrough in biology, Gerry Rubin and Allan Spradling, in 1982, manipulated transposable elements in the fruit fly *Drosophila* so that it could be used for the insertion of cloned genes into the germ-line of flies. They inserted these cloned genes in between the ends of a transposable element and injected this modified DNA into the cells of the egg that give rise to gonads of the fly. Adults that de-

veloped from these injected eggs carried the modified transposable element inserted in their 'germ-cells' and this integrated DNA could be detected in the next generation. Rubin and Allan Spradling's experiments transformed *Drosophila* biology from a study of an obscure fly by obscure humans to an area of immense general relevance. Since their pioneering work, scientists have been able to study the regulation of genes and gene products during animal development by putting genes back into flies. They have shown that the structure and function of many gene products are conserved during evolution. It seems that flies and human may actually be very similar in many aspects of their development, something that was not obvious at all.

While inserting DNA into fruit flies now appears trivial, similar transformation of other insects remains a challenge. Despite several attempts, insects such as mosquitoes and silk-worms remain refractive to transformation. Part of the reason for this has been that these organisms have been studied, genetically, far less than *Drosophila*. Another reason is the rather naive, in hindsight, assumption that transposable elements isolated in *Drosophila* will function in a similar manner in all insects. Initial

attempts with *Drosophila* elements failed, for reasons that are only now becoming clear. The analysis by Hugh Robertson and colleagues of the Mariner transposable was a major positive step. The Mariner element is present in a very large variety of insects and appears to have been acquired by these insects relatively recently during evolution. Their recent appearance and spread make them a good general candidate as a vehicle for insect transformation. One of the insects of great commercial importance is the silkworm moth *Bombyx mori*. Initial attempts to assay for the presence of the Mariner element in this moth proved negative. However, recent experiments, reported by Mathavan *et al.* (page 577) demonstrate a Mariner-like element in silkworm. This suggests that Mariner can invade this organism and perhaps be used as a vehicle for transformation. There is a long way to go before germline transformation becomes feasible and of general use in silkworm. However, intense work on Mariner and other transposable elements and tests of their ability to integrate into the germline chromosomes may make commercial exploitation of this insect by introducing genes of interest a distinct possibility.

CORRESPONDENCE

Science education for the poor

The need for broadening the Science base in India, in order to tap talent from the entire population of the country so as to make the Indian scientists more competitive in the international arena has been emphasized (*Curr. Sci.*, 1995, **69**, 287). It is heartening to learn (*The Hindu*, August 21 and 29, 1996) that the Government proposes to start Residential Schools in 100 districts in the country in order to impart quality education to the poorest of the poor. This is very much required as there is little hope for poor children (who come through the midday meal programme) to become doctors, engineers and scientists if the current trend of commercialization of education continues.

The criteria for admissions to these Residential Schools should be different. The selectors should go to the elementary schools run in the respective areas to select the best students among the poorest of the poor. Remuneration of teachers in these new Residential Schools should be much higher than for those in other

schools and they should not be allowed to give private tuition, which destroys the education system in this country. On the other hand, incentives should be provided for teachers who work hard to get the best out of their students. In addition, parents should be supported financially so that they do not take away their wards half way through.

I would urge the Government further to start 'National Science Universities' also for the poorest of the poor. One such 'elitist' university (on the IIT, IISc model) in each state, exclusively for the best among the students who come from the above mentioned Residential Schools, will be required to make them doctors, engineers and scientists. Again, remuneration of teachers of these National Science Universities should be much higher than those in other Universities so that the best will come forward to serve the poorest of the poor. Admissions to these National Science Universities at the research level can be made open to the best among all Indians. I believe that

these measures, in addition to helping the poor, will also make Indian science highly competitive.

There is a growing feeling among the common public and the political leadership that the higher education and scientific research are toys of the rich. This is one of the reasons, for the present reluctance of Government to spend scarce resources on higher education. If the science leadership and the academies come forward to help the poorest of the poor, no Government will ignore higher education and science. I strongly believe that we still have leaders among us who will appreciate and come forward to implement these ideas as they will not like to miss a chance to become the 'messiahs' of the poor.

RESEARCH NEWS

Vitamin A analogues and cancer

P. C. Bhattacharyya

Vitamin A is known for its role in general growth and healthy eyes. Its deficiency in diet results in night blindness. Vitamin A is essential to fight against infectious diseases such as diseases of respiratory system and diarrhoea. In nature, it occurs in two forms, retinal and dehydroretinol. Retinol is vitamin A and retinal, an

aldehyde of vitamin A, is derived from vitamin A by oxidation. The retinal differs in having one or more conjugated double bond and has approximately one-third the biological activity of retinol, i.e. vitamin A.

Majority of human cancers arise in epithelial tissues of lungs, bladder, breast,

colon, pancreas, stomach, uterus, prostate, etc. Retinoids which include retinol, retinal, retinoic acid, etc. are implicated in the maintenance of normal epithelial cell differentiation and are useful for the treatment of certain kinds of cancer, e.g. vitamin A can cure mouth cancer. Since carcinogenesis is characterized by abnor-

Retinal : R = CHO
Retinoic acid : R = COOH

mal cell differentiation, the primary need will be to use agents that can bring about normal cell differentiation. Retenoids, especially the naturals such as retinyl esters and others, can help in the prevention of cancer.

Lack of promising results by retinoids may be because these do not always reach potential sites in adequate concentrations. Because of fear of excessive storage of retinyl esters that may cause damage to the liver, there may be a failure in administration of appropriate doses. The all-*trans*-retinoic acid (ATRA), another retinoid, is used in the treatment of skin cancer and leukaemia, especially acute promyelocytic leukaemia (APL)¹. Indeed, this presents a breakthrough,

although 13-*cis*-retinoic acid has been found to have a marked inhibitory effect on the development of both preneoplastic and neoplastic lesions of the bladder. Consequently, retinoids, the structural analogues of vitamin A represent a new class of compounds with remarkable therapeutic activities. It remains for the organic chemists to synthesize further structural variations of retinoid skeletons.

Recent studies² showed interesting results on the application of supplements of vitamin A and zinc. These give protection against stomach cancer. Studies conducted in China showed that the supplement can act as the anti-cancer agent. Philip Taylor, Chief of the Cancer Prevention Studies at the US National Cancer Institute in Bethesda, Maryland, confirmed usefulness of these supplements. The research study organized by Chinese and American researchers prescribed daily intake of one of the four combinations such as vitamin A and zinc; B vitamins such as riboflavin and niacin; vitamin C and molybdenum; and an anti-oxidant especially the cocktail of β -carotene (precursor of vitamin A), vitamin E and

selenium. These researchers believe that vitamin A prevents cancer because it stops cell differentiation processing to a minimum and zinc added to vitamin A accelerates the cellular transport of vitamin A. However, vitamin A and zinc formulation is assumed to be the best. According to these workers, cancers of stomach can be reduced by two thirds.

The Harbin team found that arsenic compound in traditional Chinese medicine helped a complete remission in more than 70% of APL patients. Zhung reported³ that the side-effects were almost nil and that if there is any toxic effect, it can greatly be minimized by intravenous administration of the drug. It is believed that arsenic trioxide works differently with ATRA. The mechanism awaits elucidation.

Research Snippets (edited by K. Manjula)

A feast for the pharaoh

The art of producing beer and wines is said to be almost eight thousand years old. Ancient methods of preparation chiefly relied on exposing fruit juice and cereal extracts to air. Reports of the use of fermentation techniques during wine-making are said to date back to four thousand years ago in the Egyptian and the Babylonian civilizations. Artistic descriptions indicate that bread and beer were the staple food of the Egyptian civilization. Earlier documented evidence of this ancient culture indicates that coarsely milled wheat used for making bread was in fact well-kneaded but full of chaff and grit. Baked bread was sometimes crumbled and strained through sieves into vats with water to initiate the process of making beer (*Biotechnology of Malting and Brewing*, by J. S. Hough).

More direct evidence was further

obtained from remains recovered from tombs and settlements dating throughout the Pharaonic period. Examination of such remains would provide reasonably authentic evidence as the Egyptian climate allowed for good preservation of the starch content of the food specimen. Earlier studies relied on the use of light microscopy of samples such as the pots wherein liquor was stored as well as food packed into Egyptian mummies for the next life. Results were often obscure and unreliable due to a poor resolution of the starch granules. A study conducted by Delwen Samuel (*Science* vol. 273, 26 July 1996) has interesting facts about how the ancient Egyptians baked their bread and brewed their beer. The study relied on the use of Scanning Electron Microscopy in order to systematically analyse desiccated loaves and cereal residues obtained from a site where Egyptian workmen built tombs in the Valley of Kings and Queens. The focus

of attention was analysing the physical properties of starch granules that are known to vary according to the method used during the food processing. When starch (a polymer of glucose units linked together through glycosidic bonds) is heated in water, the starch granules swell, fold and merge. Depending on the water content of the food sample, the starch granules either remain discrete or fuse together creating hazy boundaries (as revealed through an SEM). The study has revealed that the microstructure of Egyptian bread resembled that of the modern bread with some loaves even leavened by the use of yeast. Contrary to the older belief, brewing was done not by a crude method but was in actuality a two-step process. Heated and malted cereal grains were mixed with unheated and sprouted grains, decanted and fermented to produce Egyptian beer. Cleopatra obviously wined and dined her guests in style!

Finicky flights of fancy

With the curtains drawn on the recent Olympic Games held in Atlanta, a question that seems to haunt the mind of many a physiologist is how far the Olympic motto can actually be stretched. How high, how swift and how strong can today's athlete become? Ehsan Masood wonders (in a briefing in *Nature*, vol. 382, 4th July 1996) how far this 'record-breaking' could last. Roger Woledge, professor of physiology from the University College, London believes that where the performance of the human body is concerned, there is certainly a limit. After all, the human race cannot be likened to an in-bred racehorse. A recent study conducted at University of California compared the metabolic rates of 37 species including human beings. In most cases, the ratio of the metabolic rates (that actually indicate the energy level) between subjects in the sleep phase and the active phase did not exceed 7:1. Even when unlimited food was provided to the subjects, this rate did not vary significantly. In retrospect, while improved training, sports equipment, clothing and nutrition may indeed enhance an athlete's performance, no one can really go on and on. There seems to be a well-meaning dot that punctuates every hundred metre dash.

'Y' are we so hungry?

Mechanisms that balance the food intake and the energy expenditure can determine whether an individual is fat or thin. A couple of years ago Jeffrey Friedman, from the Howard Hughes Medical Institute, identified the 'obese gene' from mice, whose protein product actually regulates this balance. The counterpart of this gene in the humans codes for a protein called 'leptin' that can suppress the appetite of an individual and increase the metabolic rate. Later, Millenium Pharmaceuticals succeeded in identifying the corresponding receptor situated on the cell membrane

that binds to the leptin molecules. The protein entering the cell in this manner would then proceed to execute a particular metabolic function. Any aberration either in the obese gene or in the gene coding for its receptor protein is said to result in obesity. Even while Millenium Pharmaceuticals is involved in the formidable task of designing drugs to control obesity, the attention has now been diverted to a neuropeptide that seems to possess a master control of the feeding habits of an individual.

A few years ago, peptide hormones were in the news because of the crucial functions they are able to execute in the human body. PYY, one such hormone that is secreted by the pancreatic cells, has a unique amide attached to its C-terminal tyrosine group. This was later found to bear an uncanny resemblance to the Neuropeptide Y (NPY) that is widely distributed in the limbic regions of the brain. Earlier results have indicated that NPY binds to specific receptors of the 'Y' class. This class of receptors (Y1, Y2, and Y3) is found in mammals and can bind to such peptides with varying affinities resulting in the triggering of a biochemical signalling pathway.

Evidence so far indicates that the signal triggered by the NPY-receptor binding regulates the feeding habits of the individual. Attempts at identifying the receptor have finally yielded results, according to a recent report in *Nature* (Gerald *et al.*, vol. 382, 11th July 1996). The total mRNA (which acts as an intermediate in the DNA-to-protein transition) isolated from the hypothalamus of a rat was converted into a complementary DNA (cDNA) library using conventional methods in genetic engineering. The cDNA molecules were later introduced into an expression cloning system, where conditions allow for the DNA to be decoded into its corresponding protein. When the protein products were exposed to labelled NPY molecules, the protein that bound chemically to the labelled protein was fished out and its properties studied. This protein (that is actually the receptor) is said to bear scant resemblance (as judged by its amino acid sequence analysis) to the

older receptor molecules, and has been duly named the 'Y5' receptor. In humans, the Y1 receptor identified earlier also bound to the NPY peptide. So in what way is the new Y5 receptor (that has also been identified in humans) related to Y1? For some unknown reason, the genes coding for the Y1 and the Y5 receptors map to the same locus of the same chromosome but in the opposite orientation.

Using the rat as the model system, an elaborate study of the Y5 receptor was conducted starting with the localization of this receptor in various tissues of the brain. Evidence now points out that through an intricate circuitry created by the receptor location in the brain, NPY may also regulate the emotional aspect of feeding behaviour. Y5 is clearly the best candidate for studying and understanding the physiology and psychology of feeding behaviour and that includes several feeding disorders.

The 'not so sweet news'

Aspartame is a high intensity artificial sweetener which is being marketed under various brand names like 'Equal', 'NutraSweet' and 'Spoonful'. A recent report in the Journal of Diabetic Association of India' (Vol. 35) cautions the indiscriminate use of this sweetener that can lead to as many as 90 different documented symptoms including headaches, visual problems, and even heart palpitations. Aspartame, (which is L-Aspartyl Phenylalanine Methyl Ester) can breakdown in the body into amino acids and methanol. As there is no ethanol in Aspartame to counter the ill-effects of Methanol, it can lead to several of these undesirable side-effects. The FDA, however, claims that a daily dose up to 50 mg/kg body weight is safe.

India – Economic liberalization and biomedical and health sciences research*

V. Ramalingaswami

A cliché 'Think Globally and Act Locally' is doing the rounds in the corridors of the World Health Organization in Geneva. It reflects the spirit of discussions at this symposium on 'Indian science after liberalization'.

The spirit of liberalization

The 'fact sheet' distributed at the meeting lists a series of measures that the Government of India took in 1991 to 'unshackle the Indian industrial economy from the cobwebs of unnecessary bureaucratic control'. It lists a number of measures such as abolition of industrial licensing, direct foreign investment up to 51% foreign equity, entry of private sector in areas hitherto reserved for public sector, etc., but as Mashelkar said earlier, the true spirit of liberalization is the important thing.

Performance indicators

An objective discussion of the issues under the rubric of Indian science after liberalization is possible only when there are objective indices of performance in various sectors. Such indices are not easy to come by as yet and so a discussion in depth on this topic is not yet entirely feasible. One has to indulge largely in a qualitative reflection.

Basic science indicators

As Herman Bondy said, basic science is the well-spring of modern technology. One yardstick of measuring the impact of liberalization on Indian science is to see to what extent creativity and advances in basic sciences had been stimu-

*Based on comments made at the Indian Science Writers Association – 4th National Convention – in a symposium entitled, 'Indian Science After Liberalization' at New Delhi, on the 3rd May 1996.

lated as precursors of innovative technologies. The whole field of transforming findings in basic science to meaningful application in resolving health problems affecting vast numbers of people needs attention¹.

There is evidence that India's capabilities in basic biological science research in fields such as molecular biology, molecular genetics, immunology and cell biology are now pretty well developed. The scene is set for exploitation of this capability for economic growth through a biotechnological revolution subserving medical and health care².

The concept of partnership with industry is articulated beautifully in the Council of Scientific and Industrial Research document: *CSIR 2001 – Vision and Strategy*³. It is not enough to liberalize the economy through the series of measures promulgated by Government. The atmosphere must be conducive to the effective implementation of those measures and to bring about active collaboration between science and industry. This has been the Achille's heel of Indian science. However, there are signs that basic discovery and application are moving closer together in India. Even so, the sight of so many biotechnological diagnostic products developed in Indian laboratories lying unabsorbed into the health care system in a major way is all too common. This is an area, I would suggest, needs most urgent dialogue between science, industry, government, representatives of the health care system and the public.

Product indicators

Science has to be 'manipulated' into processes, products and devices and this can be quantitated to measure performance. The journey from a laboratory-based technology to the market place is the most crucial one for the Indian sci-

entific enterprise as alluded to already. It is an enigma to friends of India as to why India had been unable to jump on to the band-wagon of market economy despite the presence of a very significant science and technology infrastructure. The situation in this regard may be beginning to change.

Products and patents are the hallmarks of today's market economics. I would broadly endorse Mashelkar's comment: 'Patent before you publish'. It is like saying 'look before you leap'. It is time to de-emphasize the slogan 'publish or perish' but publication of one's work in peer-reviewed journals and its presentation in scientific fora must continue to be the general rule within these guidelines in today's world.

Social impact indicators

If science is to be the foundation of economic progress as well as social well-being, social impact indicators, although they may take time to reveal themselves, would be legitimate criteria to look for the impact of liberalization on Indian science. One obvious reflection would be to look at the poverty line, whether it is moving up or down as a function of time. The debates on how much poverty there is in India tend to become abstruse⁴. But, on the whole, whether it is government's or academicians', the data indicate a decline in the poverty figures, although understandably, in the case of government figures, the data are more impressive – a decline in poverty figure from 25.5% of the population in 1987–88 to 18.9% in 1993–94 (ref. 4).

There are other indicators such as infant mortality, life expectancy, employment, IQs and growth of children, environmental quality, and indicators pertaining to the well-being of women. Data on these are badly needed but instant changes should not be expected.

Joint ventures

There are apprehensions that opening up Indian S&T enterprise to foreign collaboration might erode into the dearly-held Indian policy of self-reliance. It must be remembered that in entering into joint ventures between Indian and foreign industry one has to negotiate from a position of strength. True partnership seeks to leverage complementary strengths and overcome weaknesses of individual partners⁵.

Privatization, disease palaces and the face of liberalization

To the ordinary citizen, the impact of liberalization on medical science in India is the overnight erection of large tertiary care institutions in urban areas. These may serve a useful purpose in making high quality care available largely to those who can afford the costs involved. As it is often claimed, they may also liberate the public hospitals from expropriation of their services by the privileged sections of society and enable more services from these hospitals to flow to the low-income groups. Large tertiary care institutions in the private sector are required by law by the state governments to make available a proportion of their caring services free of charge to those who cannot afford them. How this formula works in meeting the health care needs of the poor, even in a small and significant way, is a matter for further study. If it is largely serving as a conscience pacifier, how can this powerful force for health be modified and channelized to attain better equity in services? I know of several physicians working behind the high walls of these institutions who are looking for approaches by which these institutions could be linked to public sector health care institutions to provide back-up support, thus becoming integral parts of mainstream-caring services to the people. In countries like India which have a dual system, in reality a pluralistic patchwork of services, the subtle connections between public and private sectors in health care need careful analysis. The social and economic im-

pact of less restrained use of technology in treating individual patients needs to be evaluated⁶. The practice of medicine today is filled with an aura of high technology, expensive medical procedures, excessive laboratory investigations and the high drama of life-saving interventions. It creates stresses on resources, especially acute in low-income countries. How to cope with these stresses in such countries, particularly with the push of privatized health care and how to maintain a balance with considerations of equity in mind, constitutes one of the major challenges of economic liberalization in resource-poor countries.

From a population health standpoint, it is the effect of any reform on primary health care that is of utmost significance. Equally, how the reform addresses the issues of supportive referral services from primary to secondary and tertiary care level needs to be ascertained and mid-course corrections applied.

Plant-derived therapeutic substances

The directing of chemistry of natural products to the relief of human ailments and maintenance of human health is another aspect of the liberalization – health care equation. Intensive research for new therapeutic substances from natural sources is required – a process which has already begun. The discovery of bio-active natural products from Indian medicinal plants is an area of considerable significance for the health care of India's teeming millions. In line with the great legacy of India in this regard, much effort is being expended in Indian research laboratories in pursuit of this goal. Some progress has been made in this direction and several speakers have already alluded to this. This could be yet another indicator of liberalization and health sciences. There are immense opportunities for the discovery of new natural products against challenging diseases for which either the existing therapeutic substances are ineffective *ab initio* or the microbial pathogens transformed from sensitive to resistant strains. It is quite conceivable that plant

genes could be discovered that code for novel molecules of preventive or therapeutic or immunomodulatory value.

Conclusion

In a discussion on science and technology and the economy, there is a need for objective data on the trends in R&D expenditure, the areas of basic research that impact on the economy and in the case of biomedical and health sciences, advances in medical sciences and biotechnology and their impact on health care of people, not ignoring equity issues⁷.

It would be appropriate to conclude with the observations made by Douglas Black, past President of Royal College of Physicians, London, who said of market economies: 'There is an overconfidence in the beneficence of the market and an underawareness of the difference between a business and a service. Is managerial efficiency more important than the skills and dedications of doctors?'⁸.

India needs a National Biodiversity Conservation Board

T. N. Khoshoo

India's stakes in biodiversity are very high not only because it is a country rich in biodiversity but, out of the twelve centres, it is also a very important centre of origin of agri-biodiversity. Furthermore, the country as a whole is predominantly biomass-based with largely bio-industrial pattern of development in an unusually large number of villages, where over 76% of its population lives. The country is also a signatory to the Biodiversity Convention (1992), but such a decision was taken without any serious consultation with the scientific community. This has resulted in India landing itself into a situation where policy on biodiversity has overtaken the underlying science and technology. A major issue is how well scientific and technical knowledge can be harnessed into public policy. This paper summarizes India's strengths and weaknesses in this area and urges that the Government of India appoint a small scientifically and technically sound National Biodiversity Conservation Board. This would not only enable to prepare a cadre of conservation biologists, but also help to generate products and give the requisite bargaining power to the country in the international arena during negotiations.

In common parlance, biodiversity may be defined as species richness (plants, animals and microorganisms) in a given habitat be it on land, in fresh water or sea, or as parasites or symbionts. Biodiversity is critical to the very health and stability of the biosphere and renewability of biomass, soil, water and air, together with oxygen, carbon, nitrogen and phosphorous cycles. Thus biodiversity renders free recycling and purification services together with natural pest control.

A subset of biodiversity is *genetic diversity* which occurs in the form of interbreeding *populations* of a given species. Populations of different plants, animals and microorganisms in a given habitat, existing as an interacting system, are known as *communities*. An aggregate of communities occurring as an interacting system in a given ecological niche makes an *ecosystem*. Different ecosystems in an ecological region occurring as an interacting system constitute a *biogeographical province*. All biogeographical provinces in a major ecological zone constitute a *realm*, and all realms on the surface of the earth together constitute the *biosphere*—the living mantle around the world occurring on land, in fresh water and in sea. Biodiversity is also the source of all living materials used as food, shelter, clothing, biomass energy, medicaments, etc. and host of other raw materials used in bioindustrial development. These along with metallic and non-metallic minerals constitute the basic wealth of any country. Ultimately, economy and ecology of a country depend on the health of these resources.

There is increasing pressure on natural habitats due to growing human population and enhanced pace of socio-economic development. This has led to the degradation of parts of earth's biosphere, and has resulted in loss of biodiversity and agricultural productivity. Such losses of species *are for ever* and affect not only plants, animals and microorganisms in nature together with those under cultivation/domestication and used in industry, but also those whose value has yet to be ascertained.

The evolutionary history of earth is replete with examples of both extinction of old and origin of new species taking place simultaneously. Infact, geological times have witnessed five major episodes of extinction because of the cataclysmic events, but today's accelerated rate of extinction episodes can be traced only to the influence of human race. Therefore, steps need to be taken to halt such species losses. There is also a need of a well-conceived and dynamic programme of biodiversity estimation, conservation and sustainable utilization.

The over-all estimation of the extent of biodiversity in the form of plant cover and forests in different habitats (including deserts, water bodies, coastal areas, etc.) would come under the purview of Department of Space and Forest Survey of India (MoEF), particularly the former because theirs would be a third party evaluation thus more credible. Periodic (say 5-yearly) reports from these bodies are needed to monitor all habitats for the extent of biodiversity. These data would be useful to take up work on ecorestora-

tion of degraded habitats. Such surveys may also help in calculating the overall quantity of biomass, i.e. all living matter plant, animal and microorganism come under its purview.

The entire *in situ* conservation falls within the mandate of the Ministry of Environment and Forests (MoEF) together with some aspects of *ex situ* conservation, like conservation of complete organisms being attempted in field gene banks in botanic gardens, arboreta, zoos, zoological parks and aquaria (Figure 1). However, use of modern technologies in conservation of organism parts, falls primarily under S&T departments like Department of Agricultural Research and Education (DARE), Indian Council of Forestry Research and Education (ICFRE), and secondarily under Department of Biotechnology (DBT), Department of Scientific and Industrial Research (DSIR) and Department of Science and Technology (DST). These include biological banks for seeds, pollen, sperms, eggs, embryos, tissues, microorganisms and genes (in the form of DNA). A well-managed network of such banks of parts of plants and animals, and microorganisms already exists in the ICAR. This Council has national bureaus on soil and land use, and plant, mammalian, avian, fish and microorganism genetic resources. Some of the bureaus have very large holdings in *ex situ* form. In addition, a large number of collections exist in the Institutes working on crop plants (e.g. wheat, rice, maize, sorghum, potato, tuber crops, sugar cane, cotton, jute, ground nut, gram, soya bean, edible oil crops, pulses, mango,

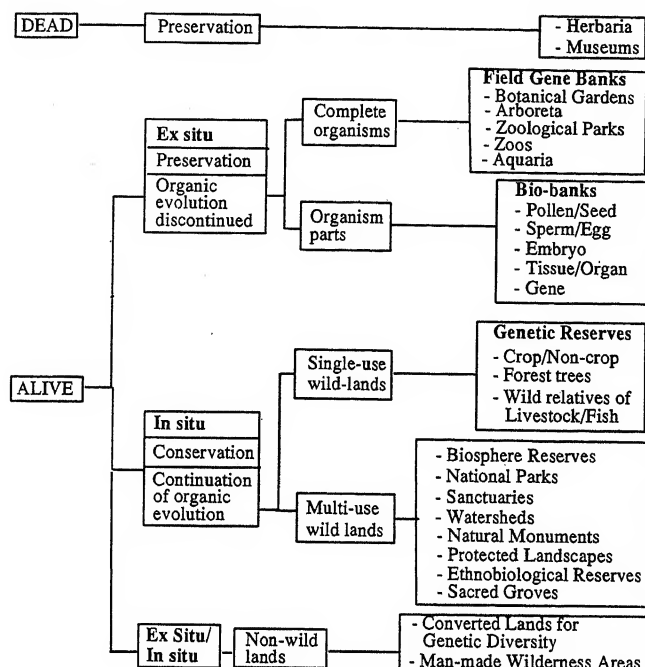

Figure 1. Options of conservation.

citrus, cashew, banana, grape, tobacco, medicinal and aromatic plants, spices, plantation and horticultural crops, mushrooms, orchids and other flowers, etc.). Among animals large collections exist in the case of cattle, buffalo, pig, sheep, goat, poultry, camel, mithun, yak, fish (freshwater and marine), aquaculture, lac, etc. In these Institutes there is also basic S&T infrastructure and capability, together with long-term funding available for this purpose. Additions/replenishments have to be made carefully and should also include all the important endangered and rare species; and ancestral and other related species, land races and primitive cultivars of agricultural crops and domesticated animals for purposes of breeding better types. A network of such banks has to be organized to save the relevant materials under threat of endangerment or extinction. This network should act as Native Germplasm Saver Societies of old and discarded varieties.

Biodiversity in India

The Botanical and Zoological Surveys of the country have estimated that as of today India's biodiversity constitutes 126,188 species¹. These cover all the five kingdoms, namely *Monera*, *Protista*, *Fungi*, *Animalia* and *Plantae*. According to the World Conservation Monitoring

Centre², 1,604,000 species have been described at the global level. Thus India accounts for 8% of the global biodiversity existing in only 2.4% land area of the world.

The country has a coastline of over 7516 km long, a sizeable exclusive economic zone (2.15 million km²) and a large shelf area (0.13 million km²). EEZ is about two-third of the area of main land. Marine areas are by and large still to be systematically charted for biodiversity. There is an abundance of seaweeds, crustaceans, molluscs, corals, fish, reptiles and mammals.

Biodiversity exists at three major levels: *genetic diversity*, *species diversity* and *ecosystem diversity*. *In situ* conservation at the species and ecosystem levels of diversity fall under the purview of MoEF. The first level (genetic diversity) involves the actual utilization and is the concern of DARE, DBT, ICFRE and to a small extent, of DSIR and DST. Thus from genes to ecosystems, there is indeed a continuum³.

Of late, there has been increasing preference and demand for biodegradable products obtained from different forms of biodiversity. Excessive demand for such products would surely lead to bio-depletion of natural biota. There is not only an urgent need for the bioenrichment of the depleted species, but also for evolu-

ing strategies that would prevent bio-impoverishment in natural habitats. MoEF is principally responsible for this and has to harness professional expertise across the whole spectrum for this purpose. Unfortunately, this has not happened so far because these are very few science and technology-based ecorestoration programmes.

Biogeographical provinces

Udvardy⁴ recognized eight realms in the biosphere of the earth. These have been discerned based on a holistic approach. Each realm is infact a complex of related Biogeographical Provinces which number 193. India falls in two realms, with a total of 12 Biogeographical Provinces⁵, which are listed below:

- Palaearctic realm: Tibetan (Ladakh), Himalayan Highlands.
- Indo-Malayan realm: Malabar Rain Forest, Bengalian Rain Forest, Indus-Ganges Monsoon Forest, Assam-Burman Monsoon Forest, Mahanadian, Coromandel, Deccan Thorn Forest, Thar Desert, Laccadive Islands, and Andaman and Nicobar Islands.

The foregoing 12 Biogeographical Provinces have six broad ecosystem types⁵. These are: Tropical Humid Forest, Tropical Dry or Deciduous Forest (including Monsoon Forest or Woodlands), Warm Deserts and Semi-deserts, Cold Winter (Continental) Deserts, Mixed Mountain and Highland System (with complex zonation) and Mixed Island Systems. This classification does not take into account the marine ecosystems and the interface between land and sea, and freshwater and sea. Such interfaces are also rich in biodiversity.

Rodgers and Panwar⁶ have done a detailed exercise, taking into account all the previous classifications including that of Meher-Homji⁷. According to them, the country can be divided into 10 Biogeographical Zones and 25 Biotic Provinces. These are: Trans-Himalayan (Ladakh); Himalayan (North-West, West, Central and East Himalaya); Desert (Kutch and Thar); Semi-desert (Punjab and Gujarat-Rajwara); Western Ghats (Malabar Coast and Western Ghat Mountain); Deccan Peninsula (Deccan Plateau South, Central, Eastern, Chhota-Nagpur and Central Highlands); Gangetic Plains (Upper Gangetic and Lower Gangetic

Plains); North-East India (Brahmaputra valley and Assam hills); Islands (Andaman, Nicobar, Lakshadweep Islands) and Coasts (West Coast and East Coast).

These authors⁶ have taken into account 'land-planning regions of India, largely on geomorphological considerations'. The underlying rationale has been the mega animal part of India's wildlife, rather than the sum total of India's biodiversity. They feel 'some species are characteristic or indicators of certain habitats (e.g. pheasants in temperate Himalayan communities); other species (such as tiger) are dominant member of communities. Ensuring the long-term survival of such animals means that the communities and habitats are also protected'. However, they feel that, for such purposes, 'in general, animals are used more often than plants, mammals are used more than other animal groups, and larger species are used more than smaller ones'.

The report has also brought out that in 1987, there were 54 national parks and 372 sanctuaries with a total area of 109,652 km² or 3.3% of the area of the country. After their review and identification of new sites, they recommended that the country should have 148 national parks and 503 sanctuaries which totals to 151,342 km² or 4.6% of the country's total area.

The report of Rodgers and Panwar⁶ is indeed an excellent effort but takes a traditional view of wildlife. However, today wildlife is regarded as a part of overall biodiversity so as to make the former more holistic. It must encompass the whole gamut of plants, animals and micro-organisms. This change is necessary, because the traditional concept of wildlife is rather restricted in outlook. This laudable report is now a decade old and MoEF has yet to take a decision on the recommendations and publish the report for wider circulation and use.

Hotspots in India

Among the 18 hotspots in the world⁸ two are in India. These are two disjunct areas: Eastern Himalaya and Western Ghats. Their floral wealth is particularly rich so is their endemism not only in flowering plants but also in reptiles, amphibians and swallow-tailed butterflies. Western Ghats have endemic mammals as well.

Apart from the two foregoing mega 'hotspots', 26 endemic centres have been identified by Nayar⁹. These are: Karak-

oram and Ladakh of Kashmir Himalaya; Kumaon-Garhwal Himalaya; Siwaliks; Terai; Sikkim Himalaya; Arunachal Pradesh; Lushai Hills; Tura-Khasi Hills; Aravallis; Chhota-Nagpur Plateau; Panchmarhi-Satpura Range; Simlipal and Jey-pore Hills of Orissa; Bastar and Koraput Hills; Vizagpatnam Hills and Araku Valley; Tirupati-Cuddappa Hills; Marathwada Hills; Saurashtra Kutch; Mahabaleshwar-Khandala Ranges of W. Ghats; Agumbe-Phonda Ranges of W. Ghats; Ratnagiri and Kolaba Ranges; Nilgiris, Silent Valley and Wynad; Anamalais of W. Ghats; Palni-Yercaud; Kalakad and Agasthyamalai Hills of W. Ghats; Andaman Island; and Great Nicobar Island.

The northeastern region is the home of some botanical rarities. One of these is *Sapria himalayana* which is a parasitic angiosperm and has been sighted only twice since 1836. The flowers are about 35 cm across and buds are about the size of a grape fruit. Besides this, Sahni¹⁰ has enumerated several such vanishing taxa. The region is meeting ground of Indo-Malayan and Indo-Chinese biogeographical realms as well as Himalayan and Peninsular Indian elements. It may be recalled that it was here that the Peninsular plate struck against Asian land mass, after it broke off from Gondwanaland. It is, therefore, not surprising that the northeastern India is the region where a large number of primitive angiosperm families are also found. These are: *Magnoliaceae*, *Degeneriaceae*, *Himantandraceae*, *Eupomatiaceae*, *Winteraceae*, *Trochodendraceae*, *Tetracentraceae* and *Lardizalabaleaceae*. The primitive genera are: *Alnus*, *Aspidocarya*, *Betula*, *Decaisnea*, *Euptelea*, *Exbucklandia*, *Haematocarpus*, *Holboellia*, *Houttuynia*, *Magnolia*, *Mangelia*, *Pycnarrhena* and *Tetracentron*¹¹. Takhtajan¹² was led to believe that this region along with contiguous regions is the cradle of flowering plants. Furthermore, Janaki Ammal's¹³ outstanding cytogeographic work has shown that northeast India, together with contiguous region of Chinese provinces of Yunnan and Szechwan, is a very active centre of organic evolution. This has now been confirmed by studies in South East China where an altogether new large mammal (*Muntiacus gongshanensis*) and four new genera (*Xizangia*, *Sinoleontopodium*, *Sindoxa* and *Tetradoxa*) of flowering plants have been discovered¹⁴. Such is the biological riches of NE India and the

adjoining SE China. This region needs special attention.

Although the two areas (North Eastern Himalaya and Western Ghats) are today disjointed having their own characteristic flora and fauna, the following species are common to both^{15,16}. *Ternstroemia japonica*, *Rhododendron arboreum*, *Hypericum hookerianum*, *Thalictrum javanicum*, *Cotoneaster buxifolia*, *Parnassia wightiana*, *Lonicera ligustrina*, *Gaultheria fragrantissima*, *Symplocos lauriana*, Himalayan and Nilgiri Tahr, Nilgiri Pine Marten, laughing thrush (associated with genus *Rubus*), great pied hornbill, frogmouths, fairy blue bird, lizard hawk and rufous bellied hawk-eagle. The probable explanation for the presence of common species between the two disjunct regions is an indication of their being Pleistocene relicts. According to this view, during Pleistocene glaciation, temperate flora and fauna moved south. On retreat of the glaciation, temperate relicts were left at higher altitudes of the southern mountains and continuous distribution between northeast and southwest India was lost after the Pleistocene glaciation. This is the most plausible explanation⁷.

According to Hora¹⁷, there is also resemblance in fish fauna between the two disjunct areas. However, he advanced Satpura Hypothesis, which envisaged movement of Assam flora and fauna through Satpura System to Western Ghats. Whatever be the explanation, the fact remains that the northeast and southwest floras and faunas have some degree of commonality. The common species listed above need detailed genetic study including genetic fingerprinting to establish the relationship between the two groups of disjunct biota in space and time.

In the Indian subcontinent, five sites have been recognized internationally that are not only rich but are also priority sites for data sheet treatment². These are: Agasthyamalai Hills, Nallamalais, Nilgiri Hills, Namdapha, and Nanda Devi. Agasthyamalai and Nilgiri Hills can be categorized as distinct floristic provinces, often covering a very wide area. Together these constitute a centre of plant diversity and/or endemism covering the whole region. For conservation to be effective, a network of smaller reserves needs to be established because it may be impracticable to protect the entire area. Namdapha and Nanda Devi are discrete geographical areas needing conservation.

Endemism and extinction

The most reliable work on endemism in flowering plants of India has been done by Chatterjee¹⁸. Most of the subsequent work has depended on this detailed study. According to him, there are 6850 endemic species in India out of which 3165 (about 50%) occur in the Himalaya. Among the largest genera in India are *Impatiens* and *Primula* with a high degree of endemism. The former has 189 species, about 112 of which grow in the Himalayan belt, while 77 species in Western Ghats, with only one species (*I. balsamina*) common to the two disjunct regions. *Primula* has 162 species out of which 148 are endemic¹⁸. Endemic birds are found in western Himalaya, Indus valley, Western Ghats, eastern Himalaya, Nepal, Bhutan, Bangladesh, Assam Plains and Tirap Frontier with Burma². In higher vertebrates, the country has 12% endemism in mammals, 7% in birds, 40% in reptiles and 53% in amphibia. Andaman and Nicobar has 93% (75 out of 81 species) richness in endemic land snails. Overall, India has 90 species of mammals, 110 species of birds, 158 species of reptiles and 110 species of amphibians endemic in the Indian region^{2,19}.

Data on threatened species may be relatively more reliable. It appears about 1336 species of flowering plants, 39 species of mammals, 72 species of birds, 17 species of reptiles, 3 species of amphibian and 2 species of fish are threatened.

Though no professional studies have been made on the extinction of biota in India, the following species appear to have become extinct in India. These have not been sighted for a long time².

- *Rhodonessa caryophyllacea* (Pink Headed Duck) around 1935 possible cause has been over-hunting.
- *Athene bleinitii* (Forest owlet) around 1914.
- *Ophrysia superciliosa* (Himalayan Mountain Quail) cause was over-hunting. According to Salim Ali it was last sighted in 1876. There is however, a recent unconfirmed report of its sighting in Uttarkhand.
- *Rhinoceros sondaicus* (lesser one-horned rhino) extinct in India but occurs in Java.
- *Acinonyx jubatus venaticus* (Cheetah) extinct in India in 1939, but occurs in Central and Southern Africa and perhaps also in parts of Middle East.

- *Isoetes dixitii* (Isoetaceae) from Maharashtra. Extinct in 1868.
- *Isoetes sampathkumarii* from Karnataka.
- *Lastreopsis wattii* (Aspadiaceae) from Manipur.
- *Ophiorhiza brunonis* (Rubiaceae) from Karnataka and Kerala.
- *Ophiorhiza caudata* from Kerala.
- *Ophiorhiza radicans* from Kerala and Sri Lanka.
- *Wendlandia augustifolia* (Rubiaceae) from Tamil Nadu.
- *Trochetia parviflora* (Sterculiaceae) from Meghalaya.
- *Sterculia khasiana* (Sterculiaceae) from Meghalaya.
- *Eragrostis rottleri* and *E. rangacharli* (Graminae) from Tamil Nadu.
- *Hubbardia hepataneuron* (Graminae) from Karnataka.
- *Dipcadi concanense* and *D. reidii* (Liliaceae).
- *Urginea polyphylla* (Liliaceae).
- *Corypha taliera* (Palmae).
- *Hedychium marginatum* (Zingiberaceae) from Nagaland.
- *Calanthe whiteana* (Orchidaceae) from Sikkim.
- *Prasophyllum colemaniae* (Orchidaceae) from Meghalaya.

Although the loss of foregoing 24 species has come to light, there may be many more species which have become extinct. A systematic study has to be initiated by BSI and ZSI involving the university system.

Centre of origin and diversity

All crop plants and domesticated animals can be traced to their wild ancestors. They have arisen both through inadvertent and deliberate selection by human being. The degree of dependence of these plants and animals on human being is directly proportional to the extent and nature of transformation that has taken place from the wild to the cultivated/domesticated condition. The crop plant genetic resources of the world can be assigned to specific centres of diversity as originally identified by Vavilov²⁰.

Vavilov identified these on the basis of varietal diversity, homologous variation, endemism, dominant allele frequencies and disease resistance. The centres are located in different continents. These have also been referred to as Germplasm Treasures (for details see Khoshoo⁵).

While Vavilov's²⁰ basic conclusions

have stood the test of time, there have been small differences about the number and location of centres of diversity. There is today a general unanimity about 12 centres of diversity²¹. India is one very important centre having contributed to world agriculture at least 167 plant species^{5,21}. Within the overall mega Indian Centre of Diversity as recognized by Vavilov, there are at least nine subcentres of diversity, where wild relatives of cultivated plants still occur²².

One indeed marvels at the intuitive power of our very remote ancestors to have picked up these plants from the wild, and selected these unconsciously and consciously so as to make them far different and highly productive compared to the ancestral stock. Some of these are being cultivated world wide, e.g. rice, sugarcane, cucumber, egg plant, banana, citrus, ginger, etc. Among animals, the three important animals (chicken, cattle and pig) supporting world animal husbandry, chicken (*Gallus gallus*: jungle fowl) is India's contribution. The cultigens and domesticated types both in plants and animals have been crafted meticulously and are different from the ancestral species. Like cultural and developmental diversity, agri-biodiversity is also a part of the creative diversity of human being. All these diversities are mutually supportive and reinforcing.

There are secondary centres of genetic diversity which are environmentally different from the primary centres, where the crops were developed further by human ingenuity. Thus India is a secondary centre of diversification for several species which are very old introductions (may be even pre-Columbian) into the country. Such crops are grain amaranths, maize, red pepper, soybean, potato, oil palm, etc. Similarly, the Indian breeds of exotic and domestic animals like horse, pony, sheep, goat, cattle, etc. are always in demand particularly for their disease resistance and hardy traits. The reason is that these animals are the result of hardiness, adaptation to heat, parasitic stresses, and availability of roughage with low nutritive value and, therefore, these are in demand for breeding purposes in Australia, USA and Latin America.

National Biodiversity Conservation Board (NBCB)

By their very nature, most Indians are

peace-loving and vegetarian, and believe in non-violence which is enshrined deep into their psyche. Thus conservation is basically a part of Indian ethic. It is, therefore, not unexpected that in the historical past, India had a tradition of giving highest attention to wildlife. In the recent times, the country had a powerful Indian Board for Wildlife (IBWL) headed by the then Prime Minister of India, Indira Gandhi. This continued up to her assassination. After her, the Board has met *only once*. What it means is abundantly clear!

There is, however, no doubt that the concept behind IBWL has outlived its utility because there is a need to widen its scope and make it holistic. Even the World Wildlife Fund, from which many rich Indians have been drawing inspiration, was compelled to change its name to World Wide Fund for Nature by sheer circumstances of new and vastly extended knowledge on biodiversity. However, for the sake of continuity and convenience, they continued to have the same acronym: WWF. Theoretically, wildlife means all undomesticated plants and animals, but in practice it was restricted to large mammals, big cats in particular. This was so on account of a feeling that these animals were top of the food chain. The underlying rationale was: if big animals are conserved, *ipso facto* others below them are also conserved. This may not be correct under all circumstances and can, therefore, be a fallacious argument. In India due to the outstanding work of the late Salim Ali, birds have been studied very intimately. There has also been outstanding work done on algae, fungi, liverworts, mosses, ferns, gymnosperms besides angiosperms. The same is true of different groups under the animal kingdom. All this work is scattered and needs to be organized into a modern database.

Today, the concept of wildlife has widened considerably. It includes all biodiversity as a dynamic and interacting system, of which even the local human beings are also an integral part. It is not merely the number of microorganism, plants and animals, but the most important point is the interconnectedness, interrelatedness and interdependence of plants, animals (human beings included) and microorganisms existing as a system. There is also a very definite connection between biodiversity and cultural diversity, together with social, economic, historical, religious and philosophical dimensions.

Such a relationship is mutually reinforcing (Khoshoo, unpublished). Biodiversity is now looked upon as a major renewable resource and hence an important Earth Capital. If we take away biodiversity from the Earth, human beings cannot exist. Conversely, if we were to take away human beings from the surface of earth, biodiversity (except agri-biodiversity which has been created and crafted by human beings) will continue to exist, may be even flourish. Human race must realize this.

This country has done nothing worthwhile, although we made tall claims after signing the Biodiversity Convention at Rio in 1992 and thereafter. It may also be pointed out that biodiversity is not to be mistaken for mere animal welfare and such other populist measures, but there is whole range or scientific, technological, social, economic, ethical, moral and political disciplines involved in it.

Furthermore, throughout rural India, there are innumerable microenterprises at the village level using local biodiversity. The products from the same find their way to cities and even in international market. These are exotic and often exquisite items and are in demand. There have been very few dependable studies on such enterprises. There is need to document and analyse these with a 'cradle to grave' approach. With a little innovation, such studies can be linked not only provincially, but also nationally and some even globally. Sufficient attention has not been paid to these aspects except for the outstanding studies of K. S. Bawa and his colleagues. Their work has attracted world attention. As a whole this area is indeed uncharted and if work is done professionally, it would also give us an inkling about the economic value of the products obtained from our biodiversity. Regrettably, Indian biologists have not played their part well. The vacuum thus caused has been filled by a host of non-biologists. The professional biologist of the country must now take a lead lest the whole area of biodiversity should fall in wrong hands.

Another dimension is that there is considerable illicit trade in wild animal parts and plants, e.g. tiger bones, claws, skin of tiger and other cats, rhino horns, butterflies, orchids, herbal drugs and aromatic plants, sandalwood, etc. It is clear that animal and/or plant producing countries are in developing world in South America,

Meso-America, Africa and South East Asia, but ultimate destination of the traffic in biodiversity is USA, Canada, West Europe, Japan, Middle East and China²³. On paper, India is neither a producing nor a receiving country, but considerable illicit trading in biodiversity comes to light once in a while.

Techniques like DNA fingerprinting can be used to identify such threatened and rare species. This technology has become very important because it enables unequivocal identification of the concerned species. Not only do target species need fingerprinting but also their adulterants. In addition, the diversity within the species needs to be charted and related to their chemical profile particularly in the identification of high-yielding strains of the concerned phytochemicals from drug and aromatic plants. Work on genetic fingerprinting has to be intensified and fingerprints obtained on most cultivated/domesticated and wild biota (human diversity included). All this information has to be collected in the form of a proper database and related to the uses of different cultivars, ecotypes, chemotypes, etc. Such information together with species-specific and even gene-metabolite linked probes will also be of help in standardization of bio-pharmaceuticals and biodiversity-linked intellectual property rights, etc. For some critical species (endangered species like lion and tiger), such a technique will also give us an idea of the extent and nature of genetic variation so as to decide an effective strategy for its conservation based on principles of population genetics and breeding biology.

These sophisticated techniques need to be applied on a systematic basis to genetically, economically and trade-related biodiversity. Such a sophisticated database is going to be also critical to biodiversity conservation and utilization. Besides, it will have tremendous social, economic, ethical, and legal implications.

The foregoing aspects of biodiversity have to be accompanied by teaching and training in Conservation Biology: a new multidisciplinary subject which is becoming increasingly critical to the conservation and sustainable utilization of biodiversity particularly in developing countries. Advanced teaching and training in this discipline has to be started in some chosen conventional and agricultural universities and Wildlife Institutes so as

to generate a cadre of well-trained and knowledgeable conservation biologists.

An important and an integral component of Conservation Biology will be a proper economic valuation of India's biodiversity. In fact it is a part of larger problem of proper economic evaluation of different forms of the Earth's capital (air, water, soil, minerals, etc.). Biodiversity has an indirect and a direct value. Indirect value pertains to the overall biological productivity of an ecosystem, fresh air and water, soil, regulation of climate, and ecotourism for sheer greenery and fresh air and clean water and good viewing of wild animals and plants in their natural habitats. The direct value pertains to the level of community use of timber and whole range of non-wood forest products, genetic resources of crops and domestic animals and their ancestral and other related species. Putting a price tag on our biodiversity will make its loss more understandable because it would be in fiscal terms. At present economic value of wild biodiversity (be it a medicinal or aromatic or fruit plant or whatever) is the cost of travel to collect the same, and no more. Those who make products, make the real money. However, it is the end-user and nature at large who pay the real cost.

Policy decisions regarding biodiversity have to be taken realistically, based on

actual facts. Therefore, there is need to consolidate information and put it in the form of a major database commensurate with the biodiversity wealth of India.

Being predominantly a biomass-based country with largely bioindustrial pattern of development, India's stakes in biodiversity are indeed very high. Our performance in this area has been far from ideal. This is true even in its legal and political dimensions. At any rate, it is not commensurate with the extent and nature of bio-wealth that India owns. There are reasons for this. The result has been that biodiversity which is India's strength has been progressively going by default even when internationally biodiversity has assumed considerable importance. It is high time that Government and scientific and economic communities and responsible social scientists think about it very seriously. The least that can be done is to organize a competent and responsible organization so as to give proper importance and treatment to this wealth for the good of the country.

The information on biodiversity is very dispersed and needs to be consolidated so that the country can reap rich harvests from this important wealth. There is, therefore, a very urgent need of having a comprehensive and a professional National Biodiversity Conservation Board

(NBCB) which can look at various aspects of biodiversity, ranging from environmental, to biological (including agricultural), social, economic, ethical and other related dimensions. The three broad functions (Figure 2) are the establishment of database(s), and management and utilization of India's biodiversity. The National Database(s) will store data on all the five kingdoms. Other equally important databases would deal with agricultural and industrial biodiversity. Here information of wild and human-created and crafted useful microorganisms, domesticated animals and cultivated plants together with their ancestors and related species and other relevant dimensions will be stored. It is indeed gratifying to note that this country already has a chain of very prestigious national bureaus of plant and animal genetic resources under the aegis of ICAR.

Indian Council of Forestry Research and Education (ICFRE) must take up the responsibility of conservation of forest tree germplasm, both under *in situ* and *ex situ* conditions in a meaningful manner^{15,24}. Forest tree germplasm and lack of proper forest tree genetics and breeding programmes have been major lacunae in forestry research and development. This is why our wood productivity is indeed dismal, being the lowest in the world²⁴.

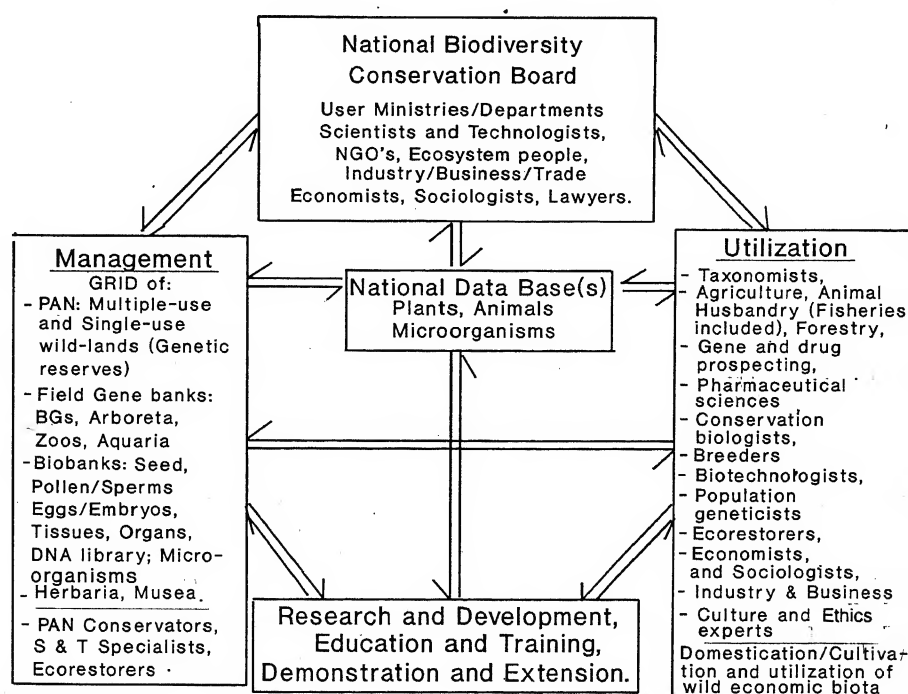

Figure 2. Broad functions of the National Biodiversity Conservation Board.

It may also be pointed out that the Ministries/Departments/Organizations involved with NBCB would be Environment and Forestry, Agriculture, Industries, Commerce and their relevant Departments (DARE, DBT, DSIR, DST), ICFRE and those dealing with commodities like tea, coffee, jute, cotton, silk, tasar, rubber, cashew, coconut, arecanut, phytochemicals, biopharmaceuticals, biocosmetics, bioinsecticides, biopesticides, biofertilizer, etc. The total membership of the NBCB should under no circumstances exceed nine otherwise it will be only a talking body.

Of late, there has been a realization in the industrial countries that local technical knowledge of the indigenous people in the developing countries is not mere collection of myths and voodooos, but distilled knowledge accumulated over millennia. Such knowledge is based on large scale trial and error and intensive observation. Regrettably, this knowledge is regarded as 'ownerless' and is taken for granted as *Common Heritage*. There is now major effort by industrial countries to own all such 'ownerless' knowledge and resources. After its updating and refining, in industrial countries through the application of relevant upstream S&T, this knowledge would be regarded as *innovation* and *intellectual attainment* and would become patentable. It would then be rewarded and awarded as private property and become available to only those who can pay the high price. All this has led to renewed emphasis on ethnobiology, ethno-medicine and ethno-pharmacology. This aspect of biodiversity has also opened up new vistas in ecology, biology, economics, micro-enterprises, anthropology, linguistics (particularly local languages), community development, conservation, etc.

In view of the foregoing, *the time has come that the country must declare biological diversity a National resource, its conservation and sustainable utilization a National goal and National priority*. The functions of NBCB have been worked out¹⁵ and need to be refined further. These need to be periodically looked at indepth and updated. An illustrative list of functions is given below:

- Formulate a National Policy on conservation and utilization of India's biodiversity and agrobiodiversity together with a time-bound plan of action.
- Inventorize India's biodiversity.

- Establish minimal database(s).
- Review existing PAN (Protected Areas Network), identify gaps and draw criteria for identification of new protected areas.
- Examine tenurial security of PAN to ensure conservation in perpetuity.
- Prepare plans for management of PAN, ensuring stake and involvement of people.
- Support PAN with adequate number of genetic reserves, botanical and zoological gardens, arboreta and aquaria, and biological banks of organism parts including DNA.
- Draw plans for ecorestoration of degraded habitats.
- Draw plans for *ex situ* conservation together with rehabilitation of endangered species (e.g. tiger, rhino, lion, pheasants, butterflies, wild medicinal and other economic plants, etc.) based on genetic-evolutionary considerations.
- Draw criteria for endangerment of species leading to extinction together with causes for the same and suggest remedial measures.
- Draw conservation and sustainable utilization plans regarding hitherto neglected areas like marine biodiversity, forest tree genetic resources and microorganisms.
- Following principles of population and evolutionary biology and genetics and breeding, domesticate wherever necessary, wild biota that are in demand in trade, e.g. medicinal and aromatic plants, ornamentals, butterflies, fish, fur animals, botanical and zoological rarities and teaching materials.
- Draw plans for meaningful involvement of local people in conservation effort and in community biodiversity programmes.
- Establish centres for research and development, teaching and training and demonstration and extension in conservation biology, ecorestoration of habitats; economic value of ecosystems, species and genes; trade in biodiversity, particularly in endangered species; microenterprises at the village level; and indigenous people and their local technical knowledge.
- Build a cadre of PAN conservators and S&T specialists.
- Establish centre(s) of study for legal and policy aspects relating to conservation and utilization of biodiversity.
- Guarantee financial support.

Finally, it may pointed out that in its wider context, the poor and struggling developing countries of the world in tropical/subtropical belt are particularly rich in biodiversity, but are very poor in its utilization using modern science and technology. There are definite reasons for this²⁵. There is also an immediate need for an indepth discussion for forging ahead an alliance between all or most biodiversity-rich but technology-poor developing countries so as to deal with biodiversity-poor but technology very rich industrial countries in an effective and a gainful manner²⁶.

If this is not done, the onslaught of concealed compulsions from industrial countries will keep developing countries (rich in biodiversity and local technical knowledge) in *permanent bondage*. Therefore, the most urgent need is to professionalize and technicalize the whole area of biodiversity, if not the whole area of environment.

Indian Bioresources Council

Over the years there have been suggestions made from India and abroad regarding organizing inter-ministerial and an all-encompassing Indian Bioresources Council (IBC). Bioresources as a whole are indeed very critical for the development of India, because, as pointed out earlier, this country is essentially a biomass-based and predominantly rural country, where the pattern of development has to be bio-industrial rather than purely industrial. There are already several Councils under Government of India dealing with bioresources (including human being), e.g. Indian Council of Agricultural Research, Council of Scientific and Industrial Research, Indian Council of Medical Research, Indian Council of Social Sciences Research, etc. In addition, there are Councils on Ayurveda, Unani, Siddha systems of medicine. The basic raw material for all these councils is biodiversity of sorts (including human). These councils have rendered yeoman service. Having IBC over these, would, therefore, be adding a layer of administrative hassles. It would be counter-productive. However, a NBCB will be more pointed and focused organization to oversee in entirety conservation and utilization of the principal bioresource, i.e. biodiversity.

Note added in proof: An important publication on Hotspots of Endemic Plants by M. P. Nayar has been just published by the Tropical Botanic Garden and Research Institute. This is an update on Chatterjee's (1939) paper referred to in the text.

Indian cycads cry for protection

E. J. H. Corner who was professor of Tropical Botany in the Botany School, University of Cambridge has aptly said, 'But the forests which show how trees were made are dying, they are vanishing nowhere faster than from the alluvial plains where the vestiges of the last creative phase of plant life that prepared the way for the modern world may survive.... Before machines the forest is defenceless. Human progress is clearing it with gathering speed to plant crops for quick returns'. It is, therefore, necessary to conserve the plant cover of tropical forests, and therein specially the cycads, need to be conserved. Being relics of a bygone age they are handicapped by their slow growth, relatively short stature, disadvantageous dioecism, sex ratio problems including less frequent coning of female individuals, frequently non-synchronous production of male and female cones, their inefficient pollination mechanisms, shedding of seeds with immature embryos and a long period of about 10 years required by seedlings to attain puberty for producing reproductive parts. Accordingly in various native coun-

tries of cycads, except India, there is public and governmental awareness about the need of conserving cycads against human interference.

My visits to Beaulieu-sur-Mer in southern France in 1987, to Australia in 1990 and my recent visit to China in May 1996 to attend the International Conferences on Cycad Biology have convinced me that other countries are far ahead of India in the conservation of cycads. The Cycad Societies of USA, South Africa and China and the Palm and Cycad Societies of Australia and New Zealand have played a vital role in creating such awareness about protecting their cycads *in situ* (in the areas of their occurrence) and *ex situ* (under cultivation in gardens, parks and in private collections).

In situ conservation

As a result of this awareness all native countries have started protecting their natural populations of diverse cycads in protected areas. In China alone there are about 20 or more natural population reserves where cutting of any parts of cycads or even the collection of fallen

seeds is prohibited. Australia and Central America have also taken steps to protect their rare cycads. South Africa in particular has already enacted legislation to protect its cycad populations and to punish the guilty with fine and imprisonment. India, on the other hand, cannot claim even a single Cycad Reserve anywhere in the country, perhaps, because we are over-emphasizing biotechnology, agricultural production and applied sciences.

Ex situ conservation

Despite the limitations of cultivated collections of cycads, lasting conservation is offered to cycads, by various botanical gardens of the world. Some of these are situated in temperate or cold temperate countries (where the climate is not favourable for growth of cycads in the open), e.g. in the Royal Botanic Gardens at Kew in UK, the St. Petersburg (Leningrad) Botanical Garden of Russia and the Glasnevin Botanical Garden of Ireland and they all have stupendous collections of the cycads of the world. Many South African Botanical Gardens,

Cycas circinalis plants in the Nagamangala area. The top of one of the trees has been cut out.

the New York Botanical Garden and the Fairchild Tropical Garden of Miami, Florida need special mention. Practically every important city in Australia has a botanical garden and many of them give particular attention to cycads, specially the Royal Botanic Gardens in Sydney. Many of the above mentioned gardens are also involved in cycad research. The Chinese too seem to be ahead of us in the *ex situ* conservation of their cycads. Their South China Botanical Garden, Panzhihua Institute of Horticulture, Panzhihua Park and Shenzhen Fairy Lake Botanical Garden have special collections of cycads. In particular, the Shenzhen Fairy Lake Botanical Garden has an international centre for *ex situ* protection of cycads where not only Chinese cycads but cycads from other countries have been introduced. Whereas we cannot claim even a single botanical garden, with a good collection of our own cycads, or of diverse cycads of the world.

Indian cycads and the need of their conservation

Indian region can claim only six species

of the genus *Cycas* as its natives; *Cycas beddomei*, *C. circinalis*, *C. nathorstii*, *C. pectinata*, *C. rumphii* and *C. siamensis*. Out of these, *C. beddomei* is one of the most circumscribed endemics among all cycads growing only in the Cuddapah Hills of Andhra Pradesh. It is accordingly listed in Appendix I of the Convention on International Trade in Endangered Species of wild fauna and flora (CITES) which is administered by the United Nations Environment Programme. Its inclusion in Appendix I indicates that it is one of the endangered plants of the world and international trade in these plants or their parts is prohibited by CITES. However, their protection in India is our responsibility.

Our second species, *C. circinalis*, is relatively widely distributed from Kerala northwards up to Orissa. However, it has at least three varieties having a more restricted distribution: *C. circinalis* var. *circinalis* grows in the Malabar region, var. *swamyii* grows in the Hassan District of Karnataka and var. *orixensis*, in the Mals of Puri.

Among the remaining species, *C.*

nathorstii is endemic to Sri Lanka, *C. pectinata* occurs in the Someshwar Hills of Bihar, the Assam region, Eastern Nepal and Sikkim Terai, *C. rumphii* grows in the Andaman and Nicobar Islands and Sri Lanka and *C. siamensis* is reported rarely from Manipur and Bhutan.

The above-mentioned restricted populations of our cycads are regularly ravaged by inhabitants of the surrounding areas for use of their leaves, the entire crowns of leaves and apical parts of stems for decorations of their temples, churches or graves. The plants are also used for medicine and food. Thatching and preparation of mats and broom sticks are other uses of cycad leaves. Cones are also used for driving away bed bugs or rice bugs.

However, the worst calamity which is overtaking our cycads is the wanton destruction of their entire populations for acquiring their habitats for human habitations including dwellings, fields and roads or for quarrying stones. In this process the habitats of cycads are rapidly shrinking and the species are threatened with extinction as happened in the case of *Encephalartos woodii* in Africa where only male plants survive in cultivation. These are vegetatively propagated from a multistemmed male which was the only plant ever collected from nature in 1895. *C. beddomei*, despite being listed in Appendix I of CITES as one of the most endangered cycads, with an embargo on its international trade, has been mercilessly destroyed in Tirupathi where an entire hillside inhabited by its beautiful plants was cleared of the vegetation by the authorities of the Tirupathi Devasthanam for their buildings, roads and gardens.

At this point I can also recall the merciless cutting of a number of large female trees of *Cycas revoluta* growing in the old Government House of Allahabad. Each of these had about 60 or more large and small branches all round and these grew from the ground surface to a height of about four metres. The thickest of their trunks must have been about a metre in diameter. Their sight was so amazing that I used to take my students and botanist friends to see them. Suddenly one day I came to know that all of them had been cut down and the branches thrown away because the State Government had decided to convert the Allahabad Government House into the Moti Lal Nehru Medical College. The trees must have been planted at least

about two hundred years earlier. Obviously, no one, not even the Government cares for such valuable monuments of nature. If the authorities concerned had cared the trees could have been carefully dug out with the roots and transplanted. In other countries old cycads are valued and protected wherever they grow. The Chinese and Japanese plant cycads in their temples and some of their famous oldest and largest trees are situated there, e.g. the Ryugeji Temple near Tokyo has many old trees of *Cycas revoluta*. Surely we could emulate this practice in our temples and churches instead of decorating them with cut leaves and crowns.

Suggested methods for conservation of Indian cycads

The manner in which India could embark on a programme for the protection of its cycads is envisaged as follows:

1. A survey of the natural areas and

population counts of all our cycads in an All-India basis along with a search for new forms.

2. Protection of their habitats by declaring some of their habitat areas as 'Cycad Reserves'.

3. A programme should be embarked for the education of the public in the areas of our cycads and also elsewhere on the need of protecting our cycads wherever they grow, and, if necessary, we should embark on legislation for the protection of cycads in nature and old plants in cultivation. We should have a Cycad Society, if necessary subsidized by the Government, for education and research on cycads like the cycad societies of other countries. This could help us in developing our much needed research on different aspects of cycads.

4. India should have a few cycad gardens and special cycad sections in all botanical gardens. Indeed India needs many more botanical gardens in different parts of the country to preserve the diversity of its flora.

We could encourage cultivation of cycads in parks, road sides and private gardens by providing a subsidy for the purpose.

In this connection it is important to point out that Indian scientists sitting in positions of power in Government Departments should take effective measures for the protection of our endangered species like *Cycas beddomei* and not merely write articles about their imminent extinction. Such statements should also be backed by actual surveys of their distribution and numbers and by the establishment of 'plant sanctuaries'. India has a number of 'National Parks' for the protection of animals facing extinction but not a single one for the protection of its endangered plants. Perhaps, I could also blame myself for this situation since I repeatedly refused positions in Government Departments.

SCIENTIFIC CORRESPONDENCE

Evolution of the nasuta-albomicans complex of *Drosophila*

During the last two decades, the *nasuta* subgroup of the *immigrans* group of *Drosophila* has attracted the attention of taxonomists, cytogeneticists, biochemists, molecular biologists and evolutionary biologists. The *nasuta* subgroup has evolutionary peculiarities, which include little morphological differentiation despite their distribution over an enormous territory, the ability to intercross in the laboratory, often producing fertile offspring and substantial chromosomal evolution¹. The story started with the report of *D. nasuta* by Lamb² from Seychelles islands. Subsequently, morphologically almost similar forms found in different parts of southeast Asia were studied by Wilson *et al.*³. Further investigations by Indian⁴⁻⁷ and Japanese researchers^{8,9} resulted in establishing the 14 different species of the *nasuta* subgroup. The females of all the species are morphologically indistinguishable, while three types of males are recognized^{3,8}. On the basis of the morphology of the frons and orbits of the males, three morphophenotypic complexes have been identified^{3-5,8}. The males of

D. nasuta, *D. albomicans*, *D. kepulauan*, *D. kohkoa* and *D. neveifrons* with complete silvery frons constitute 'frontal sheen complex'. On the other hand, the silvery sheen is restricted to the sides of the frontal orbits in the males of *D. s. sulfurigaster*, *D. s. bilimbata*, *D. s. albos-trigata*, *D. s. neonasuta* and *D. pulaua*, constituting the 'orbital sheen complex'. The third complex shows absence of pollinosity of frontal region and includes *D. pallidifrons*, taxons F, J, and I.

In the frontal sheen complex, *D. nasuta* and *D. albomicans* are a pair of chromosomal allopatric races (earlier they were treated as biologically valid reproductively isolated species, and hence were given different names) with $2n=8$ and $2n=6$, respectively¹⁰. The difference in the diploid number is because the sex chromosomes and the 3rd autosome exist as independent acrocentric entities in *D. nasuta*, whereas in *D. albomicans*, these two components of the karyotype exist as one unit in the form of a metacentric chromosome. In spite of the difference in diploid number, there is similarity

between the corresponding chromosomes of *D. nasuta* and *D. albomicans*, as seen in the polytene chromosomes of F_1 hybrid larvae¹¹. They also show variation not only in chromosome number, but also in the quantum of heterochromatin present in different chromosomes¹², and in the organization of micro (dot) chromosomes¹³. Because of this difference, the size of the respective chromosomes of *D. nasuta* and *D. albomicans* differ, and this helps to distinguish the chromosomes of these races in their hybrids. In spite of such karyotypic differences, the F_1 hybrids with $2n=7$, (4 chromosomes of *nasuta* and 3 of *albomicans*) are fertile and the hybrid progeny can therefore be maintained for generations. The ability to identify the parentage of each chromosome in the hybrid karyotypes and to indefinitely maintain the hybrid populations have formed the basis for long range evolutionary studies of the present authors^{11,14}.

Hybrids of *D. nasuta* and *D. albomicans* have been maintained in our laboratory for over a decade. The F_1 with $2n=7$

breeds to yield F_2 hybrid population, which is karyotypically heterogeneous. In addition to individuals with *nasuta*-like, *albomicans*-like, and F_1 -like karyotypes, other combinations are also seen¹⁵. Such karyotypic mosaicism persists for many hybrid generations, while in some hybrid lineages, karyotypic variability disappears and the population has one type of stabilized karyotype. During the evolution of a stabilized karyotype, some of the parental chromosomes are eliminated, while others are retained. The time taken for a karyotype to stabilize ranges from 20 to over 150 generations and, in a few cases, heterogeneity is maintained without attaining karyotype stability (unpublished). Stabilized hybrid karyotypes are invariably a combination of chromosomes inherited from both the parents. Thus, a new karyotype, called cytorace was developed in our laboratory having chromosomes of both *nasuta* and *albomicans*. There are four such cytoraces^{16,17}. The males and females of these four cytoraces along with *D. nasuta* and *D. albomicans* were intercrossed and they yielded 30 new hybrid lines, which are being maintained (unpublished). Periodically, the karyotypes of these hybrid populations passing through different hybrid generations are being analysed along with other features such as mating preference¹⁸, population fitness^{19,20}, ecogenetic difference²¹, if any, among different hybrid lineages.

At present, as a result of interracial hybridization experiments for over a decade, we have created 16 different races derived from intermixing the genomes of *D. nasuta* and *D. albomicans* (Table 1) (unpublished). Details of the role of different chromosomes in the evolution of these races will be discussed elsewhere. In brief, all these hybrid populations have chromosomes derived from *nasuta* and *albomicans*. Therefore, cytologically these races are closely related to one another. They differ from one another in the hybridization path through which they have evolved and are evolving. These genetically diverged cytologically parsimonious races, evolved under laboratory conditions, constitute a new assemblage within the 'frontal sheen complex' of *Drosophila*, called the *nasuta*-*albomicans* complex. This new complex stands parallel to the three naturally evolved morphophenotypic complexes of the *nasuta* subgroup mentioned earlier.

Chang *et al.*¹ analysed mitochondrial DNA of the members of the *nasuta* subgroup and suggested that most of the lineages of this subgroup diverged from each other between 1 and 2 Myr. On the contrary, the newly established *nasuta*-*albomicans* complex has evolved/diversified within a span of one decade in the laboratory. The members of the three naturally evolved complexes of the *nasuta* subgroup exhibit genetic divergence without morphological differentiation. In this regard, the laboratory evolved *nasuta*-*albomicans* assemblage is comparable to

these natural groups. The emergence of this new assemblage is through interracial hybridization between *D. nasuta* and *D. albomicans*, followed by hybrid recombination and karyotype stabilization. The event of hybridization has hastened the process of the formation of new differentiating populations and it justifies the opinion of Dobzhansky *et al.*²², that hybridization is an evolutionary catalyst. It might have taken millions of years in nature to evolve a group of such differentiating races, but it has taken just a decade in the present experimental setup.

Table 1. Summary of the karyotypes of cytoraces along with their parental races under laboratory conditions. The superscripts 'n' and 'a' indicate *nasuta* and *albomicans* respectively

Name	Karyotypes
<i>D. nasuta</i>	(♂ & ♀) - $2n = 8 - X^n X^n Y^n 2^n 2^n 3^n 3^n 4^n 4^n$

Cytorace 9	(♂ - $2n = 6 - 2^n 2^a X3^a Y3^a 4^n 4^n$; and ♀ - $2n = 6 - 2^n 2^a X3^a X3^a 4^n 4^n$)
Cytorace 10	(♂ - $2n = 8 - 2^n 2^a X^n Y^n 3^n 3^n 4^n 4^n$; and ♀ - $2n = 8 - 2^n 2^a X^n X^n 3^n 3^n 4^n 4^n$)
Cytorace 11	(♂ - $2n = 6 - 2^n 2^a X3^a Y3^a 4^n 4^n$; and ♀ - $2n = 6 - 2^n 2^a X3^a X3^a 4^n 4^n$)
Cytorace 12	(♂ - $2n = 6 - 2^n 2^a X3^a Y3^a 4^n 4^n$; and ♀ - $2n = 6 - 2^n 2^a X3^a X3^a 4^n 4^n$)
Cytorace 13	(♂ - $2n = 6 - 2^n 2^a X3^a Y3^a 4^n 4^n$; and ♀ - $2n = 6 - 2^n 2^a X3^a X3^a 4^n 4^n$)
Cytorace 14	(♂ - $2n = 7 - 2^n 2^a Y3^a X^n 3^n 4^n 4^n$; and ♀ - $2n = 8 - 2^n 2^a X^n X^n 3^n 3^n 4^n 4^n$)
Cytorace 15	(♂ - $2n = 8 - 2^n 2^a X^n Y^n 3^n 3^n 4^n 4^n$; and ♀ - $2n = 8 - 2^n 2^a X^n X^n 3^n 3^n 4^n 4^n$)
Cytorace 16	(♂ - $2n = 8 - 2^n 2^a X^n Y^n 3^n 3^n 4^n 4^n$; and ♀ - $2n = 8 - 2^n 2^a X^n X^n 3^n 3^n 4^n 4^n$)

Races with $2n = 7$ in males show a few sterile aneuploids.

Even though some of the races appear to have similar chromosomal complement, the hybridization path and the phylogenetic history of chromosomes differ.

The present investigations can be considered as an evolutionary experimentation through hybridization under laboratory conditions. These races which are at different stages of evolutionary divergence offer a rare opportunity to study the process of raiation (speciation ?), under laboratory conditions. The *nasuta-albomicans* complex of *Drosophila*, the members of which are in the process of evolving, is a unique model system to witness the process and the pattern of sibling raiation/speciation as well as the analysis of chromosomal and molecular basis of raiation.

Evidence for positive assortative mating within *Drosophila bipectinata*

Sexual (or ethological) isolation, which is a premating barrier to gene exchange between Mendelian populations, is the most important class among the different ways of reproductive isolation in animal species. This plays an important role in evolution. The phenomenon of sexual isolation has been extensively studied in the genus *Drosophila* and has been found to be widespread^{1,2}. Incipient reproductive isolation occurring between geographic strains of the same species has been reported in many *Drosophila* species, which corroborates the hypothesis that incipient isolation originates as a side-effect of genetic divergence¹⁻³. Although a lack of assortative mating between mutant and wild type *D. melanogaster* has been reported⁴⁻⁶, selective mating has also been found in some cases^{7,8}. Rendel⁹ found selective mating (non-random) between yellow mutant and wild type with yellow males.

Drosophila bipectinata is a member of the *bipectinata* species complex of the

ananassae subgroup of the *melanogaster* species group. Population and behaviour genetical studies in this species have been initiated in our laboratory¹⁰⁻¹⁴. *D. bipectinata* shows incomplete sexual isolation with other members of the *bipectinata* complex¹⁵. It is also characterized by incipient sexual isolation between different geographic strains¹¹. Spontaneous mutations have been detected in this species¹⁶⁻¹⁸. Effects of mutations on mating propensity and pattern of mating have also been tested¹⁹⁻²¹. We detected flies with bilateral outgrowths on thorax which is a unique phenotypic change in *D. bipectinata*¹⁷. A separate stock of mutant with outgrowths could be established. During the present study, we tested the pattern of mating between wild type and mutant (possessing bilateral thoracic outgrowths) *D. bipectinata* and the results are reported here.

During the present study, the wild type (TD) and mutant (OG) stocks of *D. bipectinata* were used. In mutant stock, flies

possess bilateral outgrowths on thorax. Originally, this unique phenotypic change was detected in sepia eye colour mutant stock¹⁷. By making cross between sepia mutant with outgrowths and wild type, flies with red eye and outgrowths were obtained and a separate stock of red-eyed flies with outgrowths was established, which was used in mating propensity tests.

In mating propensity tests, multiple-choice method was used and mating success was studied by direct observation in an Elens-Wattiaux mating chamber kept in a room maintained at approximately 24°C under normal laboratory light conditions between 7 and 11 AM. Virgin females and males were collected from both the stocks and flies were aged for seven days. In multiple-choice experiment, 15 flies of each sex were used and five trials were run. Fifteen females of each of the two stocks were introduced into the mating chamber with 15 males of each of the two strains and were

SCIENTIFIC CORRESPONDENCE

Table 1. Number of matings in 60 min in the mating chamber containing 15 flies of each sex from outgrowth mutant (OG) and wild type (TD) *Drosophila bipectinata* in multiple-choice experiment

Replicates	OG ♀ × OG ♂	TD ♀ × TD ♂	TD ♀ × OG ♂	OG ♀ × TD ♂	Isolation estimate	χ^2
1	4	5	2	4		
2	6	6	2	5		
3	2	7	2	1		
4	7	6	2	4		
5	3	5	1	3		
Total	22	29	9	17	0.51	8.12*

*Significant ($P < 0.01$).

Table 2. χ^2 for 1:1 ratios on marginal totals to assess the relative mating propensities of wild type (TD) and outgrowth (OG) flies of both the sexes of *Drosophila bipectinata*

	♂	TD	OG	Total
♀	TD	29	9	38
	OG	17	22	39
	Total	46	31	
χ^2 TD, OG ♀	0.00012	$P > 0.05$		
χ^2 TD, OG ♂	2.94	$P > 0.05$		

observed for 60 min. When a pair commenced mating, it was aspirated out and the type of mating individuals was recorded. Total number of flies in each replicate was 60, and sex ratio was 1 female: 1 male.

Table 1 shows the results of multiple-choice experiment involving two strains of *D. bipectinata*. In all the replicates homogamic matings (mating between the female and male of the same type) are more frequent than heterogamic matings (mating between female and male of different types). Under the assumption of random mating, the difference between the number of homogamic and heterogamic matings was tested by calculating χ^2 . For the pooled data, the χ^2 value of 8.12 shows significant difference ($P < 0.01$) between homogamic and heterogamic matings. Thus there is a significant deviation from random mating which shows preferential (non-random or assortative) mating within *D. bipectinata*. The females of one strain prefer their own males and discriminate against alien males. The value of isolation estimate is also low (0.51), indicating sexual isolation

between two types of flies. Table 2 shows the χ^2 values calculated on marginal totals to assess the relative mating propensity of two sexes of both strains. Both types of females are equally receptive. However, wild type males are more successful in mating than mutant males but the difference is not significant statistically. Thus there is no difference in mating propensity of two types of flies.

It is evident from the present results that the thoracic outgrowths in *D. bipectinata* affect mate-recognition system, leading to behavioural reproductive isolation.

Inhibition of filarial proteases by antibodies from human filariasis

Lymphatic filariasis caused by *Wuchereria bancrofti* is a major public health disease in India. Epidemiological studies indicate that people living in endemic regions acquired resistance to the disease after prolonged exposure to infection¹, although the direct evidence for immunity in human has been difficult to establish. Probably protective immune reactions to the parasite would be multifactorial—comprising both non-specific and specific (immunological) effector components. Elucidation of natural immune mechanisms operative in endemic population will help in devising better control strategies against the disease. Immunochemical characterization of antigens, especially those having biochemical functions (e.g. enzymes), can provide data relevant to the biology of parasites. Proteases of parasites are an important group of enzymes which are actively involved in various aspects of host-parasite interactions², for example in parasite nutrition, inactivation of host immune response, and invasion of host tissues. Antibodies inhibitory to proteases were detected in animals immune to or infected with the parasites^{3,4}, thereby emphasizing their importance. Antibody-mediated inhibition of protease activities may induce arrested growth of parasites and consequently benefit the host. Indeed, proteases have been implicated in conferring resistance to many diseases like malaria⁵, trypanosomiasis⁶, dictyocaulosis⁴ and others^{7,8}.

Studies on immunological role of filarial proteases in endemic people have been initiated by us recently. They are described as allergen⁹ and immunodiagnostic antigen¹⁰ in *W. bancrofti*-infected individuals. Host inhibitory antibody response to filarial proteases, especially in humans, has remained unknown. Here we report the presence of such antibodies in filariasis and relate their generation to the severity of infection. The effect of antibodies isolated from different groups of filarial sera was studied on the protease activities in *W. bancrofti* infective larvae (L₃) that initiates human infection, adult extract (AE) of *Setaria digitata*, an immunoanalogue of human parasite and a protease fraction (Fr. III) purified from *Setaria*.

Filarial sera were collected from disease-free normal (endemic normals, EN) and infected individuals (symptomatic

Table 1. Antibody-mediated inhibition of filarial protease activity

Filarial group	Control activity remaining (%)		
	<i>S. digitata</i> (AE)	<i>W. bancrofti</i> L ₃	Fr. III
Endemic normals (EN)	100	100	100
Asymptomatic microfilaraemic (AS)	60	65	100
Chronic filariasis (CP)	30	0	0

Protein A-sepharose purified antibody (60 µg) from filarial sera was incubated with parasitic extract (10–20 µg protein) prior to azocoll hydrolysis. The extent of inhibition was expressed as the percentage activity remaining relative to a control without IgG. The means of two independent assays are shown.

chronic patients, CP and asymptomatic microfilaraemics, AS) living in a filarial endemic village (Olosingh, Khurda district, Orissa). Pooled sera of different groups of filariasis were made by adding an equal volume of serum from individuals ($n=20$ in each group). A control serum pool (NEN) was also prepared from residents of Koraput (non-filarial region) district of Orissa. IgG was purified from each serum pool by protein A-sepharose column.

Saline soluble homogenate of *W. bancrofti* L₃, *Setaria digitata* adult (AE) and an allergenic fraction with protease activity (Fr. III) were prepared as described before^{10,11}. Protease activity was measured using azocoll¹⁰, a general protease substrate. Samples (20 µl) were pre-incubated for 1 h at 37°C and 4 h at 4°C with IgG from filarial or non-endemic normal sera in 100 µl of assay buffer before performing protease assay with azocoll.

As shown in Table 1, IgG from chronic patients was the most effective in inhibiting protease activities in all preparations. IgG from AS sera partially inhibited activities in *W. bancrofti* L₃ and AE but not in Fr. III, indicating differences in antigenicity of the protease. IgG from EN and NEN (data not shown) sera was not inhibitory to the proteases.

These results indicate that neutralizing antibodies to filarial proteases were generated during natural course of human filariasis. The generation of inhibitory antibodies depends on the severity of infection. Thus chronic patients with elephantiasis and hydrocele have highest level whereas endemic normals, a group exposed to infection but non-infected, have undetectable level of these antibodies. Sera from asymptomatic microfilaraemic individuals, another infected

group in filariasis, showed intermediate degree of inhibition. It would be worthwhile to find out what triggers the generation of such protease-neutralizing antibodies during filariasis—is it related to pathological changes or immune effector mechanisms.

Contribution of fluid mechanics to recent developments in meteorology

J. C. R. Hunt

A number of general fluid dynamical, mathematical and computational questions are considered in this review relating to numerical weather predictions, namely discretization of the governing partial differential equations whose solutions on length scales smaller than that of the discretization have repeatable and characteristic (or 'eigen') elements; optimum use of data in incompletely posed problems; combining statistical and deterministic solutions, and the development of objective methods for choosing between patterns according to certain criteria. Finally the contributions of fluid dynamic and meteorological concepts as aids to human forecasters are emphasized.

THE most important application of the study of meteorology, and meteorological fluid mechanics, is the improvement of forecasting of weather and climate.

In the last century and even today people question whether forecasting is a scientific activity. This problem was raised officially in the Board of Trade and Royal Society report on the Meteorological Office in 1866, which had been founded in 1854, and was issuing two day forecast in the *Times* newspaper in the 1860s. The strictures of the report led to a cessation of forecasts for 12 years from December 6th, 1866! (It is thought that the enquiry leading to this report contributed to the depression and suicide, in 1865, of the pioneering, first director of the Meteorological Office, Vice-Admiral Fitzroy.) Taking a more optimistic view, L. F. Richardson, working at the Meteorological Office in 1913, was so sure of the value of a scientific approach that he reflected whether one day forecasting would 'resemble the process by which the Nautical Almanac is produced'. However, as we learnt later from the research on chaotic dynamical systems by E. N. Lorenz¹ in the 1960s, forecasting can never be that accurate, however elaborate the calculations or comprehensive the data on which they are based. In fact, scientific forecasting follows quite closely the principles set out in Richardson's 1922 book *Weather Prediction by Numerical Process*².

Since forecasting began, it has involved physical and fluid dynamical concepts. It still does so; but increasingly it involves mathematical and computational modelling of atmospheric processes by using the results of physical

science, particularly fluid dynamics and thermodynamics. More recently, the chemical processes in the atmosphere have also begun to be modelled with a special emphasis on their long term effects on the stratosphere, especially concentrated within the polar vortices where as fluid mechanics has shown, the horizontal diffusion can be quite weak³.

Principles and problems of numerical meteorological forecasting

The essential procedure for forecasting the atmospheric environment by numerical methods, first set out by Richardson, is (a) to divide the atmosphere into flat grid 'boxes' (that are very shallow near the ground and deep in the stratosphere), (b) using the differential equations of dynamics and thermodynamics to estimate average values of physical quantities (such as pressure and velocity) within these boxes, and (c) using the equations again; this time the equations are used to calculate how these average quantities change with time, which, like space, is divided into discrete intervals. Neither the steps (b) and (c) are exact procedures and so, not surprisingly, even at this advanced stage of numerical weather prediction, there are significant variations in how these approximations are made by different research teams (e.g. the effect on momentum transfer of deep convection⁴).

The methods used by meteorologists for calculating the effects on the larger scale 'resolved' motion of atmospheric processes on the subgrid scale are quite different to those currently used in the numerical simulation of turbulent flows, such as those applied to problems in engineering. Rather than assuming that these motions are simply unstructured chaotic eddying, an

essentially different assumption is made that within each flat box whose horizontal extent Δx is a few tens of kilometres wide and whose depth (l) ranges from a few hundreds of metres up to a few kilometres, there is a single *type* of atmospheric motion generally having a defined observational characteristic area and internal structure (e.g. particular forms of velocity, humidity and temperature properties dependent on l). This assumption is obviously not valid across weather fronts where there are steep gradients that vary in horizontal and vertical directions. Then, although the model smooths the changes across the front between the states of the atmosphere either side of it, the model does predict these changes and the mean movement and distortion of the front. However, sometimes this lack of *small scale* discrimination leads to *large scale* errors, e.g. in the form of 'cut-off' vortices around low pressure regions.

The secondary assumptions are that there are only a finite number of 'types' and that the 'types' can be defined by the values of the quantities calculated on the scale of the grid box (see Figure 1). For example, convection patterns and cloud types are found to be determined by the degree to which the local mean density and velocity gradients of the resolved scale motions are stable or unstable to small disturbances. This is approximately defined by the Richardson number, $Ri = g\Delta\rho l / \Delta u^2 \rho_0$ (ref. 5), where $\Delta\rho$ and Δu are the changes in velocity and potential density across the box.

In the language of mathematical physics one might say that atmospheric motions on the scale less than Δx have a small number of eigen-states; or in the language of turbulence specialists, 'coherent structures'.

I believe that the first person to make this bold hypothesis was Luke Howard⁶, who stated:

If clouds were the mere result of the condensation of vapour in the masses of atmosphere which they occupy, if their variations were produced by the movements of the atmosphere alone, then indeed might

the study of them be deemed an useless pursuit of shadows, an attempt to describe forms which, being the sport of winds, must be ever varying, and therefore not to be defined.

But however the erroneous admission of this opinion may have operated to prevent attention to them, the case is not so with clouds. They are subject to certain distinct modifications, produced by the general causes which effect all the variations of the atmosphere; they are commonly as good visible indications of the operation of these causes, as is the countenance of the state of a person's mind or body.

This provided the rationale of this classification of clouds that meteorologists have followed ever since. Modern meteorology agrees with Howard in attributing the physical causes to the clouds' forms. But whereas he thought clouds caused their own electrostatic fields, it is now known that they set up their own fluid- and thermo-dynamical fields; that is where science has progressed!

The numerical procedure of deriving equations that only account for the motions of the atmosphere above a certain length scale and time interval can also be performed by representing these motions and other phenomena using the 'spectral technique', in terms of sinusoidal waves – following⁷. The problems of 'averaging out' the smaller scales are similar in the two methods.

In mathematical terms, the problem has now been converted from one of calculus (i.e. solving differential equations) into a very large algebraic calculation, which, as Richardson pointed out, is rather like turning the clock back from Newton, Leibnitz and Bernoulli's analyses of curves by calculus, to Archimedes' analysis by segments!

However, even if the equations describing the behaviour of the atmosphere (at least averaging within each grid box) were exactly correct, the results could not represent the actual state of the atmosphere unless there

Figure 1.

were sufficient data, at a given time, to begin the calculations. Note that the data introduced into the simulations are point measurements; they contain only a fraction of the information about the local atmosphere recorded by a meteorological observer (cloud types at different heights, visibilities in different directions, etc.). One of the reasons why the recently developed techniques of 'data assimilation' enable the forecast calculations to make optimum use of the atmospheric and oceanic data is that, for each stage, the data is inserted in such a way that locally the atmosphere is close to a dynamic balance (otherwise a new data point would produce spurious accelerations⁸). This type of calculation, where the data and the methods are both imperfectly specified, is derived from mathematical control theory. It is beginning to be applied to engineering fluid mechanics, based on similar principles, in predicting the movement of turbulent eddies in order to control the flow by small active wall elements⁹.

Once the procedures are defined, the next general question is how to make best use of computers. The obvious choice is to reduce the size of the grid 'boxes' and the time intervals over which the atmospheric behaviour is averaged (the relative magnitudes of these boxes and intervals being approximately determined by the speed and time variation of atmospheric waves, weather patterns and the thermal radiation balance). Other choices are to increase the complexity of numerical modelling (e.g. of advection schemes) and of physical modelling, to improve the accuracy with which measurements are analysed (especially the very costly data from satellites that need to be utilized more effectively) and to spend more computer time on 'data assimilation' calculations to optimize the fit of the modelled atmospheric behaviour to the present and past data.

When operational numerical weather prediction began in the UK in the 1960s, the emphasis was on using computers to reduce the size of the grid boxes in the horizontal and the vertical and time interval. This was because most of the errors were caused by the large grid size, and because it was thought that most of the significant 'weather', especially clouds and rain, were determined by 'dynamic' processes and by the broad patterns of convergence and divergence of the horizontal wind field. This is largely true for the kind of conditions, particularly the frontal systems which dominate weather at high latitudes.

But it is not a valid assumption for weather that is strongly affected by local ground heating/cooling and evaporation, such as those occurring in continental climates, and even in the UK in summer!

Consequently, the present practice is to use increased computer capacity to improve the physical modelling and data analysis, rather more than reducing the grid-boxes' size.

Different ranges of forecasting weather and climate

Different types of calculations and data use are necessary for forecasts over short periods, and for distances that are small compared with the scale of the globe. For specific local calculations, for example wind at an airport or wind energy over a hill, the horizontal size of some 'boxes' may be as small as a few metres. However, for daily forecasts, at least three Meteorological Services in Europe now calculate atmospheric conditions on the mesoscale of 10–15 km. This kind of calculation leads to significant improvements in the forecasts of rainfall patterns, especially where there are strong topographic effects. The next step forward will include assimilation of data from weather radars and satellites, and, a real fluid mechanical challenge, more detailed flow field models, including '1½' level turbulence models.

Over a longer period, beyond the 5 days of the usual deterministic global forecasts (on a resolution of 90 km), it is found that, when slightly different data are fed into the calculation, on some occasions a number of quite different weather patterns are forecast; but in other circumstances, all the forecast weather patterns remain quite similar to each other. (This is the nearest that weather forecasting has come to make use of 'chaos' theory in practice¹⁰.) In the latter situations, the forecast beyond 5 days should be more reliable. The study of these sets of forecasts may be a way of estimating the reliability of longer range forecasts, a method being investigated in detail at the European Centre for Medium Range Weather Forecasts at Reading, as well as in the UK and US Meteorological Services. These and other services are collaborating to find the best practical use of these 'ensemble forecasts' and, just as important, the best way to communicate their results to the public and customers, possibly by a greater emphasis on making forecasts in probabilistic terms. Some Weather Services consider that these ensemble forecasts provide more useful information for improving extended range forecasts over 6 to 10 days than is provided by the information obtained with a single forecast based on reduced grid size. The greater the number of realizations in these ensemble forecasts, the greater computer time required. Despite the fact that they have to be run with larger and fewer grid boxes, the usefulness of this approach is now widely recognized.

A promising modification to these large number of 'deterministic' calculations from given data (whether actual or with some slight artificial differences) is to make forecasts, of, say, temperature beyond 5 days ahead, by only using computations of the large scale behaviour of the atmosphere, such as whether there will be a static high pressure region or a sequence of depressions carried by strong westerlies. Then this in-

formation is combined with statistical information obtained over previous years that link these weather systems with the local information required by the forecasts such as temperature and rainfall. This 'mixed' approach is proving to be more accurate than simply relying on average climatology for forecasts of up to 1 month ahead. It is valuable to certain commercial customers who have to make business decisions based on estimates of the weather 10 to 30 days ahead. Decisions based on computer modelling techniques can benefit most from these long range statistical forecasts. However, the results are of limited use to the general public who would find it difficult to make use of a forecast that is reasonably correct only above 7 times out of 10! (Note that this is a significant achievement, because if average climate statistics only were used, the accuracy would be about 50% (ref. 11).)

In some parts of the world – particularly the Sahel in Africa and NE Brazil – the good statistical correlation between the climate and the slow variations of the temperature of the upper layers of the ocean enables the UKMO to provide satisfactory seasonal forecasts of rain and temperature, that local Met. Services and government agencies find very valuable. (A critical fluid dynamic problem here is to improve the modelling of the depth of the mixed layer of the ocean, which depends on estimating the entrainment processes between a well mixed turbulent region above the 'thermocline inversion' and the stratified region below.)

The methods used for numerical weather prediction over a few days are also being applied to the numerical prediction of 'climate'. This may be broadly defined, as the statistics of the average state of the atmosphere and oceans over many years, or more precisely on the statistics defined over this period, such as the mean and extreme values of rainfall, temperature, etc. Thus, since the weather in any given month varies from year to year, the 'climate' of a country for July is determined by averaging over several years. Therefore, by definition, changes in 'climate' can only be detected by considering how the average, over say 10 years, changes from one decade to the next. It cannot be detected by comparing one or two years with each other. It follows that numerical predictions of climate are also based on calculations over many years, and therefore are not 'forecasts' in the conventional sense; no-one can predict the weather in July 2094, but it might be possible to predict the changes in climate, averaged over a decade, one hundred years from now.

In these numerical models for the prediction of climate, space is also divided up into grid boxes within which the motions are calculated over specific intervals of time. Since, even beyond a month or two, the variation in sea-surface temperature affects the atmosphere, it is clear that climate forecast models must include the

behaviour of the oceans. Calculations using a 3-dimensional coupled ocean-atmosphere model require the largest computer systems in the world. There are only 4 such installations at present, one being at the Hadley Centre of the Meteorological Office. Even these computer installations, running full tilt for a few months, only have the capacity to provide climate forecasts for periods of the order of 100 years. A major application of these models has been to forecast how average global temperatures are likely to rise over the next century as a result of increasing concentrations of carbon dioxide and other greenhouse gases in the atmosphere. By allowing for aerosols in the atmosphere, the calculations have to some extent been validated by their reasonably close agreement with the observed trends of average global warming.

Such a model was run by Hansen¹² in the USA to estimate the effects on global temperature of the aerosols caused by the eruption of Mt Pinatubo in 1991. It was predicted in early 1992 that there would be a decrease by about 0.5°C in 1992 and a subsequent rise of about 0.2–0.3°C in 1993, although these values require some correction to allow for the effects of the El Nino Southern Oscillation in the Pacific Ocean. Since both predictions have been borne out by the measurements, this demonstrates that certain features of the global climate are consistent with forecasts. Because 3-dimensional coupled atmosphere-ocean model calculations take so long to perform, computer models have been devised for exploring the effects of many different influences on the global climate. These include very long term effects of variations of the radiation emitted by the sun, or wobbles in the earth's orbit about the sun, both of which lead to seasonal fluctuations in the solar radiations reaching the earth ranging from 2% to 10%. In these models, the behaviour of the atmosphere around the whole surface of the earth at each height is averaged; in the mathematical analysis the atmosphere is divided up, not into boxes, but into concentric skins (like that of an onion). Instead of a million boxes there are now about one hundred layers. Then the state of the atmosphere is calculated in each layer (or onion skin). It has been possible to run such '1-dimensional' models over periods of 10,000 years or longer and simulate many of the climate changes of the ice ages, which have been discovered from the analysis of gases trapped in bubbles found in ice cores.

Developments

How will forecasting improve over the next few years? There has been a steady increase in the accuracy of forecasts produced by mathematical/computational models being 'fed' by data from atmospheric measurements, and an even greater increase where they are used in

conjunction with human intervention (which I return to later). The accuracy of the 72-hour forecast now (measured in terms of root mean square error of the surface pressure) is about the same as the 24-hour forecast less than 15 years ago. It is expected that the present 24-hour forecast error (of about 2 hPa) will be reduced by at least 10% over the next 5 years (Figure 2).

There are three main reasons why further improvements will come about; firstly, research is leading to new insights into atmospheric processes and their representations in numerical models, and into the best way that data may be inserted into the models. For example, through fluid dynamic studies at turbulent inversion layers, more precise criteria are being developed to determine whether stratocumulus cloud grows in thickness, which leads to rain, and drizzle, or on the other hand, breaks up (because the turbulent eddies gain enough energy by entraining dry air from above the cloud to cause local cooling and thence sink with increasing speed), leading, of course, to clear skies. This fluid mechanics research also leads to a better knowledge of the sensitivity of the forecast, which also has to be communicated! Entrainment processes and up/downdrafts in deep clouds are also of critical importance for modelling their overall structure and internal energetic eddies. Those driven by the cooling of evaporating droplets can contribute significantly to the strength of the gusts at the ground. It is now realized that these may cause the highest gust speeds that produce sudden wind forces on structures, disrupting or destroying surface transport systems; the spatial forms of these cloud-driven gusts tend to be significantly different from those produced by boundary layer shear which we simulated in wind tunnels^{11,13}.

Once such local processes are understood sufficiently well to be modelled, their net effect has to be averaged or 'parameterized' over the grid boxes in the forecast calculations, an aspect of model development that requires some ingenuity and usually some empirical adjustment to obtain the best results. The modelling of atmospheric

flow over terrain and its effect on the terrain drag on the flow over a grid box is an active area of research¹⁴. Recent fluid dynamics research on turbulent flow over undulations and on stably stratified flow is now being incorporated into forecast models. An important development is to combine different types within one grid box; precipitating ice cloud above hill stratus can greatly increase the rainfall rate compared to stratus alone.

The effectiveness of such changes for the performance of the models has to be examined carefully with statistical techniques, as described by Hollingsworth¹⁵. Only if the sizes of the grid boxes are reduced below the scale of the characteristic motions can the processes be modelled explicitly. That is not yet practical. For small reductions in the size of the grid box, the parameterizations appropriate for each process have to be adapted to the new size because the physical processes, such as lee waves over mountains, have their own particular length scales.

Since forecasts require, in principle, updates of data in every grid box, the second way to improve forecasts is by providing data in those grid boxes where data is currently unavailable, especially 3 to 30 km above the ground at the altitude of the dominant dynamical processes. Remote sounding instruments on geostationary (at 36,000 km above the earth) and polar orbiting satellites (of which there are two at any time, each pass overhead twice a day at an altitude 850 km) measure radiation in the visible, infra-red and microwave frequency bands.

In 1993 the European experimental polar orbiting satellite ERS-1 produced global data of near surface wind speeds, by measuring scattered microwave radiation from ocean waves; the variation of the wind over several kilometres is related to the wind structure above the surface layer and has contributed to a 10% improvement in the model's accuracy over data sparse areas such as the Southern Pacific.

An excellent example of the use of satellite images in combination with computers and human operation is the forecasting of the trajectories of tropical cyclones.

Figure 2. Forecast errors: 1967–1992, actual; 1993–1997, projected.

Figure 3. Estimates of the contribution of different scientific and technological factors to the improvement in forecast accuracy.

Many of these cyclones form in remote areas where no other measurements are available, and are only detected once they have become strong enough to organize clouds into patterns that are visible via satellites. They are not always well predicted by the computer models because initially they are too small, their diameter (about 100 km) being similar to the size of the grid box of the model. After spotting a cyclone, or perhaps learning about it from other sources, a special technique is currently necessary. The human, or 'intervention', forecaster introduces into the numerical code a simple mathematical representation of the vortex to represent the central regions of the cyclone. Then its track is computed¹⁶, a particularly critical task because its direction often changes by 90° in 24 hours. A significant (30%–40%) reduction in the errors in these forecasts has recently resulted from improving the model of the 'vortex' to allow for its asymmetry and history¹⁷. More elaborate models are now under development, especially in the USA, to represent on small grids moving with the cyclone the detailed winds and precipitation within them, and thence to reduce the errors of freak forecasts. Because of the devastating effects of the cyclones, warnings based on meteorological forecasts are widely publicized on TV and other media. Actions based on these warnings by the emergency services and the public are now saving thousands of lives annually around the world.

The third element in the improvement of forecasts is the provision of greater computer capacity. In the UK Meteorological Office there has been an increased speed of calculation, from around 2000 Floating Point operations per second in 1960 on the Mercury computer to around 6 gigaflops on the current CRAY C90. Every ten years over the past 40 years the power of the computer has increased by a factor of 60, even though the individual processor elements have increased by a smaller factor (of about 10) (ref. 18). At the same time smaller 'workstations' (about 1/100 of the power of the large systems) have improved by a factor of 30 over the past decade, so that these can now be used for many of the research studies and, even local forecasts. Additional power will continue to result from increasing the number of integrated circuits within each silicon 'chip', and from steady improvements in how these chips are connected, housed and cooled within the computers – i.e. its 'architecture'.

In the conventional vector-processing computers only a few calculations (about 8 on the CRAY YMP-8) can be performed simultaneously, and all data are stored in a central shared memory. The next major step in computer architecture in meteorological forecasting has been the introduction in 1995 of massively parallel processors (MPP). A key feature of MPPs is that memory is distributed with the processors. For the first time the

architecture of the computer will correspond more closely to the nature of the processes in the atmosphere. Massively parallel computers will allow calculations to be performed at many grid points (about 100 or more) in the computer simultaneously. This MPP architecture (which is less expensive than conventional vector processors for a given level of power) should permit continued refinement of present forecast models for several further generations of computers. Although the most efficient use of this approach requires programs to be adapted specifically for this new architecture, the form of these new programmes is common to many scientific disciplines (e.g. meteorology, aeronautics, hydraulics, etc). Extensive collaboration is now under way across Europe in all these different fields of application of computational methods.

Two different advanced features of numerical weather prediction will be helped by these improvements in computers. First, instead of simply updating the calculation as new data arrives (or 'nudging' the solution), there will be greater emphasis on repeating the original calculations to fit the subsequent data more smoothly⁸. There will be many iterative cycles of calculation in this 'data assimilation' procedure which will give improved predictions by making better use of the previous data. Secondly, there will be time for the calculation of ensembles of different atmospheric states to provide the basis for the mixed dynamical and statistical methods of longer range forecasts, and to estimate their reliability.

So far there has been little discussion of the present and future role of the human forecaster. Until recently, s/he has been interpreting measurements and qualitative observations very much along the lines developed by V & J Bjerknes' Bergen School¹⁹, firstly identifying typical synoptic features and types of air mass, and then with the aid of Sutcliffe's²⁰ concepts, estimating their movement and development by inspection. These and more recent conceptual developments (e.g. the use of potential vorticity at different levels) aid the understanding and the correction of the numerical models. Interpretation of the computer output is a *scientific procedure* in which hypotheses are made and subsequently, of course, tested. It is based on a knowledge of the data that was introduced into the model calculations and of the characteristics of the one or more models that are available to the particular forecaster. It is found that skillful intervention by the forecaster often leads to a better result for the customer than is obtained by relying on the prediction of any one model, especially in those situations when the various model predictions differ. In some synoptic situations, numerical models are very sensitive to small perturbations. A classic case, that is repeated every few months, is the 'extending frontal trough', which may or may not disrupt into cut-off low pressure systems. The forecaster has to use

and interpret all the extra evidence available to him/her that is not in the model (e.g. details of cloud types, detailed humidity profiles, potential vorticity plots, etc.) to make a prediction. The forecaster has to make best use of his/her experience, including making an assessment of how the different models work in the particular synoptic conditions, and give emphasis to different aspects according to the special needs of the various 'customers' of the forecasts.

Some aspects of the human forecaster's contribution could be supplanted by 'knowledge-based' systems developed from the human experience. However, to replace the continual learning by the forecaster would first require the development of a complex self-learning 'neural-network' system. Although no one has yet attempted to do this at the synoptic level, this approach is being adopted for very short range forecasts (less than 3 hours) based mainly on interpreting radar and satellite images. In general, the human forecaster's contribution, although no longer dominant, will remain very important for the foreseeable future.

The number of users and uses of meteorological forecasts are steadily increasing. For example, forecasts are being used for an ever wider range of activities by members of the public, while aviation forecasts, which continue to be vital for the safety of those flying, are now required with greater precision for economical flight planning. Then there are the many specialized uses of forecasts in the retail industry, the oil industry, the public utilities and so on. See, for example, ref. 21. Forecasts are also needed in scientific studies of the atmosphere, and particularly in field experiments in the rapidly growing activity of environmental forecasting. The latter include the dispersion of pollution, wind forces affecting structural safety, wind energy, generation of sea waves, precipitation and flooding, environmental transport problems, and changes in the chemical composition of the atmosphere. Each of these uses requires different information about the atmosphere. As Bjerknes, who began as a fluid dynamicist, found when he was developing his ideas, new applications play a valuable

role in testing and improving all aspects of meteorological and climate forecasting.

The subject matter of this article straddles the birth of modern science and involves several larger-than-life figures – Nicolas Copernicus (1473–1543), Tycho Brahe (1546–1601), Galileo Galilei (1564–1642), Johannes Kepler (1571–1630) and Isaac Newton (1642–1727). This account will be woven in a connected and coherent way around their lives and work. Copernicus came first in this group; then Brahe, Galileo and Kepler overlapped and were in contact with one another; and after they were all gone came Newton.

MATHEMATICS, medicine and astronomy are the oldest areas of knowledge in all civilizations. In each culture there has evolved some model of the universe, some 'system of the world', as a framework within which to fit astronomical observations. For our present purpose we are concerned with the so-called medieval model. Before describing it, let us briefly look at some of the essential details about planets and their orbits (Table 1).

From ancient times till near the end of the 18th century – and this includes the period from Copernicus to Newton – only the earth and five other planets were known.

The medieval model was a combination of Greek science going back to Aristotle and Ptolemy, and later Christian theology. Figure 1 is a picture of the universe as presented by Dante Alighieri in the 13th century in his *Divine Comedy*¹. The earth is a globe at the centre. Then there are nine solid translucent crystal spheres, each centred on the earth. The first seven revolve and transport respectively the Moon, Mercury, Venus, Sun, Mars, Jupiter and Saturn in sequence. The eighth sphere carries the fixed stars. Last of all comes the ninth sphere, the Primum Mobile, which like an engine drives all the others. Beyond that is heaven, the home of God. In Aristotle's version, there were actual spheres, while later Ptolemy replaced them by circular orbits. This emphasis on spheres and circles reflected the feeling that these were the most perfect geometrical figures. There was also a sharp distinction between terrestrial

matter and phenomena, and celestial ones. In this picture the heavens were perfect and unchanging.

The medieval model of the universe slowly gave way under advances in astronomy and mathematics, over the 16th and 17th centuries. The principal blows were struck by Copernicus, Tycho Brahe, Galileo and Kepler. Let us at this point recall briefly the life and work of each of them².

Copernicus was born in 1473 in Torun in Poland. He stands at the boundary – the transition point – between medieval and modern science. For a ten-year period, from age 24 to 34, he studied in Italy at Bologna, Padua and Ferrara. He was very close to his teacher, Domenico Maria da Novara, the relationship between them being as between a guru and a shishya. Copernicus studied mathematics, astronomy, philosophy, law, medicine and theology – the times seem long gone since one could even contemplate such an endeavour. He also had direct access to Greek sources. During his sojourn in Italy, Copernicus saw the need to replace the Ptolemaic system by a simpler one in which calculations would be easier. His ideas were elaborated much later and led to his book *De Revolutionibus Orbium Celestium* (*On the Revolution of the Celestial Spheres*). He retained the notion that celestial bodies travel on circles lying on uniformly rotating spheres; in any case the data available to him was not accurate enough to show up departures from circular motions. Figure 2 shows a picture of his model of the universe³. The sun, rather than the earth, was at the centre. Then followed in sequence the spheres carrying Mercury, Venus, the earth, Mars, Jupiter, Saturn and the fixed stars. This heliocentric model had been suggested by Aristarchus in 300 BC, and Copernicus rediscovered it. In his words, as the sun is the visible form of God, 'in the centre of everything the sun must reside; in the most beautiful temple created by God, there is the place which awaits him where he can give light to all the planets'⁴.

Copernicus showed mathematically that this model could work and was simpler than Ptolemy's. However for fear of censure he presented it cautiously as a hypothesis, useful only for calculations. He also spoke of the concept of relative motions, with respect to the sun or the earth regarded as stationary; and showed that the earth both rotates on its own axis and revolves

*Invited talk presented at the Symposium on 'Interface of Astronomy with other Sciences', organized by Indian National Science Academy and held at the Indian Institute of Astrophysics Observatory, Kodaikanal, on 4 May 1995.

SPECIAL SECTION: PERSPECTIVES IN ASTRONOMY

Table 1. Planets and orbits

Planet	Mean distance from sun (million miles)	Revolution period	Number of satellites	Remarks
Mercury	36	88 days	0	Known since antiquity
Venus	67	225 days	0	"
Earth	93	1 year	1	—
Mars	142	1 year 322 days	2	"
Jupiter	483	11.9 years	16	"
Saturn	866	29.5 years	18	"
Uranus	1783	84 years	15	Discovered 1781 by Herschel in England
Neptune	2794	165 years	8	Predicted 1843–46 by Adams/Le Verrier; discovered 1846 in Berlin
Pluto	3666	249 years	1	Discovered 1930 by C. W. Tombaugh in USA

Figure 1. The medieval model of the universe, from Dante's *Divine Comedy*, 13th century.

about the sun. His book was technical and difficult for the average reader; it took some fifty years for his ideas to spread. Giordano Bruno, Galileo and Kepler were

Figure 2. The Copernican model of the universe, 1543 AD.

among the few who understood and accepted Copernicus' ideas. Bruno paid with his life in 1600; while Galileo and Kepler reinforced each other's beliefs privately, before each publicly acknowledged the new system.

Brahe came from the Swedish nobility, and was interested in astronomy and astrology. He was also a very gifted instrument maker and observational astronomer. The King of Denmark supported him handsomely to set up a fine observatory on the island of Hveen. Here he designed his own new instruments, and kept daily astronomical records meticulously for many years. His figures are accurate to within 1' or 2' of arc, about

one-sixtieth of a degree. (Recall that these were the days before optical telescopes.) This later became a treasure for Kepler to work on.

Two major discoveries of his made it clear to Tycho that the heavens are not immutable, that celestial bodies are changeable: one was the appearance and disappearance of a star in the years 1572–1574, another the passage of a comet beyond the moon in 1577. However, he did not accept the Copernican model but had a hybrid of his own – the sun and the moon circled the earth, while the other five planets circled the sun. For ease in calculations, this stood midway between the Ptolemaic and the Copernican systems.

Around 1599, due to changed fortunes, Brahe left Denmark and moved to Prague as 'Imperial Mathematician' to the Emperor Rudolph II. Kepler joined him there in January 1600, but Brahe died soon after in November 1601. Galileo admired Brahe's instruments and data but not his theories. Ultimately Brahe's data together with the Copernican model percolated to others and set the stage for major advances by Kepler and Galileo.

The lives and stories of Kepler and Galileo overlap a great deal. For convenience let us look first at Kepler and then turn to Galileo, making some comparisons as we go along. Kepler was a student of theology in Tübingen, gifted in mathematics and possessing mystical tendencies. In contrast, Galileo was led much more strongly by the power of reason and experiment. From his teacher Michael Maestlin at Tübingen, Kepler learned privately of the Copernican model. In 1594 he was obliged to leave for Graz as a high school mathematics teacher. Here while in class he had a flash of insight revealing to him a new geometrical model for planetary orbits with the sun at the centre. There were precisely six planets because there were exactly five perfect solids, and these were nested in successive spheres. The solids in sequence are the cube, the tetrahedron, the dodecahedron, the icosahedron and the octahedron. The innermost sphere lay inside the cube, touching its faces; the next one passed through its vertices, but touched the faces of the tetrahedron; and so on. The fit to the radii of planetary orbits was almost, but not quite, perfect. He wrote out his ideas, mixed with much speculation, in his book *Mysterium Cosmographicum* published in 1596, and sent copies to Galileo, Brahe and others. In this book he publicly declared support to the Copernican model – Galileo did so much later, in 1613.

The agreement of his model with the data was almost perfect. Kepler saw that to make progress much more accurate data was needed, and only Tycho had it. Kepler wrote to Tycho for help and, as it happened, simultaneously the latter invited the former to join him at Prague as his assistant. This was in 1600. Tycho had been much impressed by Kepler's work, and wanted

him to help vindicate his own hybrid model. Soon after, when Tycho died in November 1601, Kepler ended up inheriting all the precious data (notwithstanding problems with Tycho's son-in-law Tegnager).

Now Kepler set to work at a feverish pace; he did enormous calculations to improve his model, working particularly on the troublesome orbit of Mars. The period 1601 to 1619 – over which his three laws of planetary motions were discovered – was one of high drama. In brief the main steps he took were: (a) he created the true heliocentric model by placing the sun at the 'centre' of planetary orbits, modifying Copernicus' procedure of placing the geometric centre of the earth's orbit there; (b) he found that each planetary orbit lies in a plane containing the sun; (c) the orbit of Mars, which proved the most difficult, almost fitted a circle except for two data points; (d) as a result, with Tycho's accurate data, he saw that a circular orbit for Mars was not possible; (e) he also gave up the assumption of uniform speed for Mars as it traverses its orbit, allowing a speeding up or slowing down when close to or far away from the sun; (f) from the data he then discovered the Law of Areas: the radius vector from the sun to Mars swept out equal areas in equal intervals of time; (g) and again from the data he found at last that Mars moved on an ellipse with the sun at a focus. These two laws discovered in the order mentioned during 1602 were announced seven years later in the 'Astronomia Nova' but in the opposite order: the Law of the Ellipse became the First Law, and the Law of Areas the Second. Imagine waiting for seven years today before announcing laws of such magnitude!

After dealing with Mars, Kepler showed that these two Laws hold for the earth too, and then extrapolated them to all the other planets. The Third Law, which links different planets to one another, took much more work; a true search for harmony in the heavens, it was announced in 1619 in the 'Harmonice Mundi'. It states that the periods of revolution are proportional to the $3/2$ powers of the mean distances from the sun. This became the key to the discovery of the inverse square law of gravitation by Newton and others. Added to all this, Kepler came very close to the law of gravity. He saw the sun – and not angels with flapping wings – as the agent keeping the planets on their courses. But he unfortunately died before Galileo's delayed publication, in 1632, of his experimental studies on the laws of motion, especially the laws of inertia and of uniformly accelerated motion.

Galileo chose physical science in preference to medicine which his father had wanted him to pursue. He was highly respected as a mathematician at the University of Padua. Whereas in his correspondence with Kepler he supported the Copernican model, till as late as 1606 in his lectures he taught the medieval model. Only in

1613, as mentioned earlier, did he publicly express support for the Copernican view. His 'change of heart' came from his discoveries in astronomy.

During the period 1589–1591 at Pisa, his researches were mainly concerned with the description of motion: falling bodies, inclined planes, uniform acceleration. (Here we may parenthetically remark that it took Galileo several years to arrive at the concept of acceleration which to us today seems so obvious and natural!) Thanks to his work, 'for the first time, all the important features of motion – distance covered, speed, and acceleration – were expressed in terms of time. Galileo had realized that time is the independent variable in the description of motion; indeed, he was the first to time physical events. This was an extremely fruitful idea... it implied an entirely new conceptual view of the world, codified by Isaac Newton forty eight years later'. Then, in 1609, he heard that a telescope had been invented in Holland. He promptly reinvented it, and achieved even greater power. Then he turned his telescope to the heavens – and changed astronomy for ever!

Galileo saw that the moon was scarred, with mountains and valleys, hardly a perfect sphere; he found sunspots which moved. In 1610 he found four satellites circling Jupiter, all coplanar and the nearer ones circling faster. So everything in the sky did not circle the earth! And just as Jupiter with its circling moons went round the sun, so too our earth with our moon could orbit the sun. Again in 1610 he discovered the phases of Venus, just like our moon. So Venus like the earth was dark, went round the sun, and reflected the sun's light. He found moons around Saturn too, and almost saw the rings. Here was telling evidence for the Copernican theory, and the immutability of the heavens had been destroyed.

We all know the trouble Galileo got into with the Church upon expressing his views in his 1632 treatise *Dialogue on the two Chief World Systems, the Ptolemaic and the Copernican*. After this historic controversy and confrontation, he returned to his earlier studies on the science of motion, and published his results in *Discourses Concerning two New Sciences*. This is the first great modern work on the kinematics of motion. Smuggled out of Italy in 1638 and published in Holland, the message spread. To some degree Galileo was continuing an existing tradition of study of mechanics, created by the Schoolmen of the Universities of Oxford and Paris in the fourteenth century. John Buridan – probably better known for his ass – had already created the 'impetus' concept. But much he made himself, especially in showing that Aristotle's ideas about motion were untenable.

As precursors to Newton, and as the giants on whose shoulders he stood, Kepler and Galileo left him a splendid legacy – the laws of planetary motion, and the laws of mechanics. Newton synthesized and systematized

all this, discovered the Law of Universal Gravitation which unified terrestrial and celestial phenomena, and went far ahead in many ways. He accomplished the most decisive transition from description to explanation of natural phenomena.

Already around 1665 at age twenty three, Newton had conceived of the universal inverse square law of gravity, and seen that it could explain both the fall of the apple on the earth, and the moon's going round the earth. As he recalled many years later: 'I deduced that the forces w^{ch} keep the Planets in their Orbs must be reciprocally as the squares of their distances from the centers about w^{ch} they revolve: & thereby compared the force requisite to keep the Moon in her Orb with the force of gravity at the surface of the earth, & found them answer pretty nearly'⁵. But he could not proceed further for two reasons. One was the rather inaccurate data available to him at that time. The other was a major mathematical problem which he solved only in 1685: the proof that with an inverse square law of force, and no other, a uniform spherical mass acts as though all its mass were concentrated at its centre.

Now we come to the famous 1684 visit of Edmund Halley to Newton in Cambridge⁶. In January of that year, at a discussion among Halley, Christopher Wren and Robert Hooke at the Royal Society, the question arose of deriving *all* of Kepler's Laws from the principles of dynamics. Many had realized that this was the key problem whose solution was crucial for further progress. By combining Kepler's Third Law with a recent formula of Huyghens for the centripetal force, Halley had concluded that the force of attraction between sun and planet must be proportional to the inverse square of the distance between them. And he was not the only one to have found this – so had Wren and Hooke too. But Kepler had anticipated it, and Newton had used it in 1665. At the Royal Society discussion, Hooke claimed he could conversely derive all of Kepler's Laws from the inverse square law of gravity; but he would not divulge the details till the others had tried and failed. While Wren doubted Hooke's claim, Halley admitted he was unable to do this. All in all the stage was set for Halley's visit to Newton in August 1684. What transpired is best told in Newton's own reflections recorded by de Moivre:

'In 1684 Dr Halley came to visit him in Cambridge, after they had been some time together, the Dr asked him what he thought the Curve would be that would be described by the Planets supposing the force of attraction towards the sun to be reciprocal to the square of their distance from it. Sir Isaac replied immediately that it would be an Ellipsis, the Doctor struck with joy and amazement asked him how he knew it, why saith he I have calculated it, whereupon Dr Halley asked him for his calculation without any farther delay, Sir Isaac

Figure 3. Title page of Newton's *Principia*, 1686 AD.

looked among his papers but could not find it, but he promised him to renew it, & then to send it him....'

As Westfall comments, Newton was being cagey in saying he had misplaced his work—he too wanted to be careful and not let others see his calculations! The missing papers have since been found. Anyway this was enough indication for Halley to persuade Newton to publish his findings so that all the world could see what he had accomplished. This became a herculean effort lasting three years and resulting in the publication, over 1686–1687, of the '*Philosophiæ Naturalis Principia Mathematica*'—*Mathematical Principles of Natural Philosophy*—the greatest book on science ever written⁷. The title page is shown in Figure 3. It was like creating a new language with its own grammar, and writing an epic poem in it, all at once! In the *Principia*, Newton laid the foundations of classical mechanics in an axiomatic and deductive form à la Euclid, and created the framework for progress in the succeeding centuries. He picked up from Galileo's work on mechanics, and extended, systematized and completed it, all at once.

Then he applied it to his law of universal gravitation and showed how all of Kepler's Laws followed. He demonstrated that a mathematical model of natural phenomena, involving observed and measured quantities and possessing predictive power, could be built.

Newton's First Law of Motion was a restatement of Galileo's principle of inertia. Even Descartes had said that an isolated body moves in a straight line. The Second Law of Motion had been grasped by Galileo. The Third Law—the equality of action and reaction—was Newton's own and unique contribution. It became the basis and set the pattern for Conservation Principles. All this was presented against a background of clearly stated views on the natures of space and time.

The Law of Gravity as we saw had been foreseen by Kepler, but the unification of the terrestrial with the celestial was Newton's achievement. He showed that the moons of Jupiter and of Saturn going around their parent planets obey Kepler's Laws; the planets going around the sun do so; the moon round the earth does likewise. Everywhere throughout the solar system his principles of mechanics and gravity held sway. His theory for cometary orbits went beyond Kepler, and he explained the tides and many another phenomenon.

That is the story of planetary motions and the birth of classical mechanics. Newton's methods were propagated mainly in Europe by Euler, Lagrange, Laplace and others. And success followed success. One stunning episode from the nineteenth century is worth brief mention, and that is the story of Neptune. Around 1820 there remained some disagreements between theory and observations on the orbit of Uranus, and Bessel suggested there might be another planet causing disturbances. (Of course in Kepler's time the mutual influences of the planets upon one another were not accessible, but much water had flowed under the bridge since then.) In 1843 a student at St. John's College in Cambridge, John Couch Adams, completed a dissertation on this problem and calculated the orbit of the suspected new planet in detail. In 1845 he alerted the Greenwich Observatory to look for it. Independently, Urbain Jean Le Verrier of Paris showed in June 1846 that the data on Uranus could not be explained without the presence of another planet about twice as far away. He sent his prediction to the Berlin Observatory. Finally success came at Berlin: on two successive nights, September 23rd and 24th of 1846, the planet Neptune was spotted just where the theorists had predicted it would be!

Later in the century, discrepancies arose between theory and observations for the precession of the perihelion of mercury. After accounting for all known perturbing effects, there remained an unexplained precession amounting to 43" of arc per century. Faith in Newton's programme was so strong that it was assumed that yet another planet was at work—and it was named Vulcan!

But there is no Vulcan, and that problem was solved in an entirely unexpected way by Einstein's general theory of relativity. That theory gave a language to talk about a much larger world than that of the Ancients or of Newton's World System—but that, as the bartender said to Irma, is another story.

Suggestions for further reading, references and footnotes

The theme of this presentation has been so well studied for so long that excellent sources are available in plenty. Only a very select set of possible references will therefore be presented here.

Origin of the highest energy cosmic rays*

Pijushpani Bhattacharjee

Indian Institute of Astrophysics, Bangalore 560 034, India

After briefly recalling the history of discovery of cosmic rays, the present status of the subject is discussed. Cosmic-ray particles with energy exceeding 10^{20} eV have been detected. The origin of cosmic rays remains an unsolved problem in physics and astrophysics. The nature of the source(s) as well as the physical mechanism(s) responsible for endowing the cosmic-ray particles with extremely high energies are not known with certainty. We discuss some recent ideas in this context with special emphasis on the problem of origin of the highest-energy cosmic rays.

1. A brief history of cosmic rays

The story of the discovery of cosmic rays forms one of the most fascinating episodes of the history of science in the very early part of the current century. It is hard to associate the discovery of cosmic rays entirely with any one single experiment. Indeed, a number of remarkable experiments performed by a number of adventurous physicists, many of whom were tantalizingly close to the 'discovery', preceded the actual announcement of the discovery. A nice account of this history is given in the book by Pomerantz¹ which forms the basis of the historical aspects of the subject described in this section.

The Austrian physicist Victor Hess announced his discovery of 'an extra-terrestrial source of penetrating

radiation' in 1912 after a series of heroic balloon-borne experiments performed by him over the previous one year. The 'penetrating radiation' was later christened 'cosmic rays' by Robert Millikan in 1926. The word *extra terrestrial* is important here, for it was well known at the time of Hess's experiments that our own Earth is also a source of 'penetrating radiation' due to natural radioactivity of soil and various rocks.

Natural radioactivity was the 'in' physics in the closing years of the nineteenth century and the early years of the twentieth century. Within a year of the discovery of X-rays by Röntgen in 1895, Becquerel discovered natural radioactivity (in 1896). Even before the discovery of radioactivity, experiments with gold-leaf electroscope, an instrument that could measure the presence of free electric charges (i.e. ionization) in a medium, and which played a major role in the history of discovery of cosmic rays, showed presence of leakage currents associated with ionization in sealed containers even in apparent absence of any obvious ionizing source; the leakage current seemed to correspond to an average rate of formation of ions of ~ 10 ions/cm³/sec. This ionization was naturally attributed to the presence of 'radioactive material' in air and in soil. As revealed by later experiments, this conclusion was largely correct, but not entirely so!

In 1898 Rutherford established two different kinds of radioactive emissions: (i) α -rays and (ii) β -rays. The α -rays were found to be of high ionizing capacity, easily absorbable in media (range \sim few cm), and were later identified as the nuclei of ^4He atoms. The β -rays, in

*Invited talk presented at the Symposium on 'Interface of Astronomy with other Sciences', organized by Indian National Science Academy and held at the Indian Institute of Astrophysics Observatory, Kodaikanal, on 4-5 May 1995.

contrast, were more penetrating, and were quickly identified as electrons. In 1900 Villard discovered γ -rays, which were found to be very penetrating. The γ -rays suffered no deviation in external magnetic fields, which revealed their electrically neutral nature. (It was much later, in 1914, that Rutherford and Andrade were able to identify γ -rays as highly energetic electromagnetic radiation by observing reflection of γ -rays from crystal surfaces.)

In the meantime, experiments performed on the ground as well as underground continued to show the presence of leakage currents associated with ionization. Physicists like C. T. R. Wilson, E. Rutherford and many others were involved in these experiments. McClennan and others performed experiments on sea. In 1910 the Italian physicist Pacini made detailed analyses of the data of several earlier ground-based as well as sea-based measurements of residual ionization of air, and concluded that it was hard to attribute the observed residual ionization entirely to the known radioactive substances.

Was the observed residual ionization caused entirely by Earth's natural radioactivity? To settle this question an obvious experiment to do would be to measure the level of ionization of air high up in the atmosphere where the effects due to Earth's radioactivity should diminish. Such an experiment was performed by the German Jesuit Fr. Wulf in 1910. He measured a rate of ionization of ~ 6 ions/cm³/sec at ground level at Paris, and about 64% of this value when measured on top of the Eiffel Tower (~ 300 m above the ground). At the time of Wulf's experiment, γ -rays were the most penetrating form of radiation known, and any ionization associated with Earth's radioactivity at such a height was expected to be essentially due to γ -rays. However, Wulf's measured value of the rate of ionization on top of the Eiffel Tower was about 6.4 times more than what was expected on the basis of the then known attenuation properties of γ -rays in air. On the basis of these measurements Wulf concluded that there might exist another γ -ray source in the upper atmosphere(!), or, that the γ -ray absorption coefficient in air might be actually smaller than the then not-so-well known value. In retrospect, we thus see that Wulf was indeed very close to 'discovering' the cosmic rays.

It was, however, left for Hess to take the crucial step of measuring the variation of ionization *as a function of altitude*. Hess's experiments consisted of carrying a charged electroscope in an open gondola flown by a balloon filled with hydrogen – physically a rather dangerous experiment! Hess attained a height of about 1000 m in 1911 and finally ascended to about 5300 m in the following year. What Hess found was that the ionization inside his sealed electroscope first decreased with altitude, but then started to increase beyond a height of ~ 800 m, and continued to increase steadily to the highest altitudes

attained by him. Hess also made separate measurements of γ -ray absorption in air using an intense radium source which showed that γ -rays from ground were completely absorbed at a height of ~ 500 m from the ground. Hess's analysis of his data was unambiguous – it pointed towards the '... presence at great altitudes of previously unknown matter or ... of an extra-terrestrial source of penetrating radiation', a discovery for which Hess was awarded the Nobel Prize in 1936. A balloon ascent to a height of 9300 m by the German physicist Kolhörster in 1914 confirmed Hess's conclusions. The outbreak of the World War I in 1914 stopped further balloon flights until around 1922 when Robert Millikan and his coworkers in the USA undertook further balloon-borne experiments.

Millikan's initial results seemed to be contradictory to Hess's. In fact, in 1924, Millikan announced that there were 'no such penetrating radiation'. But in 1926, after a series of careful measurements of the ionization level over snow-fed lakes at different altitudes above the sea level, Millikan was finally convinced that 'very hard ethereal rays of cosmic origin were entering the earth uniformly from all directions'. Together with G. H. Cameron, Millikan went one step further; based on the prevailing (wrong!) notion at the time, that the 'penetrating radiation' responsible for the ionization of air consisted of very high-energy γ -rays, and by extrapolating the known penetrating power of low-energy γ -rays to very high energies, they tried to derive the spectrum of these cosmic ' γ -rays'. Their derived ' γ -ray' spectrum seemed to consist of discrete monoenergetic components corresponding to the binding energies of nuclei of some common elements like C, N, O, Na, Mg, etc. This, together with the fact that the process of formation of any element (starting with hydrogen as the basic element) would be expected to be associated with release of the nuclear binding energy corresponding to that element, led Millikan to conclude that cosmic rays represented 'the birth cries' of elements in 'the depths of space'. Indeed, because of this supposed 'cosmic' connection, Millikan referred to the penetrating radiation as 'cosmic rays'. In retrospect, we now know that the assumption of Millikan and Cameron that cosmic rays were γ -rays, was wrong, and so was their conclusion about the implied relationship of cosmic rays with element formation process.

We now know that cosmic rays are mostly electrically charged particles, *not* γ -rays. This came about with the discovery of the so-called latitude effect, published in 1927 by the Dutch physicist J. Clay, according to which, the cosmic ray intensity was systematically less near the equator than at higher latitudes. This could be adequately explained only if the cosmic-ray particles were assumed to be electrically charged particles. For in that case, the particles, being of extraterrestrial origin, would encounter greater difficulty in reaching the Earth's

surface near the equator where the Earth's magnetic field lines are nearly parallel to the surface, than they would near the poles where the magnetic field lines are almost vertical.

In 1930s the distinction between the *primary* and the *secondary* cosmic rays was established. The primary cosmic rays (consisting mostly of protons, and with a lesser abundance, nuclei of other heavier elements like helium, carbon, nitrogen, etc.), striking the top of Earth's atmosphere from outside at relativistic velocities interact with the air atoms in the upper atmosphere and generate a lot of other secondary particles. Indeed, the residual ionizations measured in the early experiments that led to the discovery of cosmic rays were mostly due to the secondary (and higher generation) electrically charged particles originating from the interaction of primary cosmic-ray particles in the upper atmosphere. The primary cosmic-ray particles can be directly measured only by experiments at those high altitudes at which there is practically no residual atmosphere above the detector, which correspond to heights (above the sea level) of ~ 40 km and above. Knowledge about the primary cosmic rays has been obtained by means of these high-altitude balloon-borne (and, of course, unmanned!) experiments. Satellites and space probes have also added to our knowledge of the spectrum and composition of the primary cosmic rays.

In the next section we briefly review our current knowledge of some of the general characteristics of the observed cosmic rays, in particular, their energy spectrum, flux, and composition. There are a large number of reviews and monographs on cosmic rays giving details. For a recent review and references, see, Drury². In §3 we discuss the question of origin of cosmic rays, highlighting the problems posed by recent experimental results on the extremely high energy cosmic rays (having energies in excess of 10^{20} eV). In §4 we discuss the recent idea of their having a fundamentally different origin (*vis-à-vis* the lower-energy cosmic rays) in the sense that they may not be produced by any astrophysical acceleration mechanisms (that are believed to be responsible for producing the lower energy cosmic-ray particles) but rather by some non-acceleration process, one example of the latter being production of energetic particles from decay of massive particles released in the process of collapse or annihilation of cosmic topological defects like monopoles, cosmic strings, etc. We summarize our discussions in §5.

2. General characteristics of the observed cosmic rays: Composition and energy-spectrum

As mentioned above, the cosmic rays that reach the Earth's surface are the byproducts of interactions of the

primary cosmic rays (that strike the top of Earth's atmosphere) with the air nuclei. In the following, by cosmic rays we will always mean the primary cosmic-ray particles unless explicitly stated otherwise.

The cosmic rays are mainly composed of nuclei of common elements such as H, He, C, Fe and so on, constituting almost 98% of the total composition; the rest are mainly electrons. There is also a small percentage of positrons and antiprotons, which are mostly, if not entirely, of secondary origin resulting from interactions of the galactic cosmic-ray particles with the interstellar medium. The composition of cosmic rays is different in different ranges of energy. Up to $\sim 10^{12}$ eV, the nuclear component (often referred to as the 'hadronic' component) of cosmic rays is dominated by protons (p) (about 87%), followed by the He nuclei (α) (about 12%), and heavier nuclei like those of C, Fe, etc. (about 1%). The mean abundances of various elements in cosmic rays are roughly the same as the average 'cosmic abundances' of these elements, although there are important differences for certain elements; these differences are, however, well-understood in terms of spallation of some of the heavier nuclei into lighter nuclei in collision with the material in the interstellar space. At TeV (10^{12} eV) and PeV (10^{15} eV) energies, the composition is roughly 50% protons, 25% α -particles, 13% C, N, O and 13% Fe. The measurement of the composition at higher energies becomes increasingly difficult since the flux of cosmic rays at energies above $\sim 10^{15}$ eV is so low that direct measurements are not possible—one has to take recourse to methods such as extensive air-shower techniques (see below).

The kinetic energy of the hadronic component ranges from about 0.1 GeV per nucleon ($1 \text{ GeV} = 10^9 \text{ eV}$) to extremely high energies $\sim 10^{20}$ eV and more per nucleus. (The composition of cosmic rays at the highest energies is not known with certainty; so the measured energy at high energies is usually given in terms of energy per nucleus as opposed to energy per nucleon used at low energies where the composition is known.) Between $\sim 1 \text{ GeV}$ and $\sim 10^{15}$ eV, the differential energy spectrum of the hadronic component is roughly a power-law, $\propto E^{-\alpha}$, with α lying between roughly 2.5 and 2.7. Below about 0.1 GeV, the spectrum drops off sharply because the magnetic field carried by the solar wind blowing out from the Sun sweeps these low-energy particles away from the inner solar system, thereby reducing the intensity of these low-energy particles on Earth significantly. This phenomenon is called 'solar modulation', which is stronger at sunspot maximum than at sunspot minimum.

At about 10^{15} eV, the spectrum steepens to a power-law with $\alpha \sim 3.2$. This is believed to be due to relatively large (compared to the thickness of the galactic disk) gyro-radius of the lighter cosmic-ray particles in the

$\sim 10^{-6}$ G magnetic field of our Galaxy. In other words, the galactic magnetic field is unable to contain the more energetic but lighter cosmic-ray particles (protons) within the galactic disk. Thus the overall flux decreases and at the same time the composition of cosmic rays changes towards a relatively higher abundance of heavier nuclei for which the magnetic containment within the Galaxy is relatively more effective, the gyro-radius being smaller for a heavier particle. Above an energy of about 10^{18} eV, the spectrum changes slope again, this time becoming less steep, with $\alpha \sim 2.6$ again. Recent measurements seem to indicate that the composition changes back to dominance of lighter particles over heavier ones. These 'ultra high-energy' (UHE) particles are so energetic that the galactic magnetic field would be too weak to contain them within the Galaxy, and therefore, these particles are believed to be mostly of extragalactic origin. This cosmic-ray spectrum is now known to extend to at least $\sim 3 \times 10^{20}$ eV. This is almost a macroscopic amount of energy, all of which is essentially in the form of kinetic energy. In other words, the particles have been somehow accelerated to speeds almost that of light. Where do these UHE cosmic-ray particles come from and how do they attain such high energies? These remain some of the unresolved issues in physics and astrophysics of cosmic rays. We shall return to these issues in the next two sections. For the moment, we continue with our discussion of the general characteristics of the observed cosmic rays.

The integral particle flux in cosmic rays, i.e. the total flux of particles above a given energy E , is about 1 particle/cm²/sec at $E \sim 10^{10}$ eV; about 1 particle/m²/year at $E \sim 10^{17}$ eV; and about 1 particle/km²/century at the highest energies. The particle flux is thus a steeply falling function of energy (see Figure 1). Nevertheless, since the particles themselves are very energetic, the total energy density in the form of cosmic rays in the universe is ~ 1 eV/cm³, which is comparable to, e.g. the total energy density in the form of starlight (~ 0.6 eV/cm³), or that in the form of galactic magnetic field (~ 0.2 eV/cm³). Thus cosmic rays constitute an important component of the total energy budget of the Universe.

Since the intensity of cosmic rays is a steeply falling function of energy, it becomes increasingly difficult to measure directly the charge and energy of cosmic rays as energy increases. Indeed, the particle flux of cosmic rays at energies above about 10^{15} eV is so low that balloon- and satellite-borne experiments become impractical; they have too little effective detector area to capture sufficient number of cosmic ray events for measuring the spectrum. Fortunately, at high energies, another method becomes available. This is the method of extensive air shower (EAS), discovered by the French physicist Auger and his group in the 1930s. When a

high-energy primary cosmic-ray particle (say, a proton) strikes an air atom (more specifically, say, a nitrogen or an oxygen atom) in the atmosphere, it creates a lot of secondary particles through high-energy nuclear interactions. The energetic secondary particles, in turn, further interact with other air atoms and generate tertiary particles, and so on, until the energies of the created particles fall below the threshold for the relevant multiparticle production processes. The high-energy multiparticle production processes are typically 'forward' processes, i.e. the daughter particles are produced with their momentum vectors confined within a narrow cone whose axis lies along the momentum vector of the parent high-energy particle. Moreover, the daughter particles all travel with more or less the same relativistic speed. Thus, at any time, the particles' positions lie on a thin disk, which thus propagates down the atmosphere with relativistic speed and can even reach sea level, typically if the energy of the primary particle exceeds $\sim 10^{15}$ eV. The 'disk', whose radius can be several hundred metres, can contain several millions of particles (mostly electrons and photons) depending on the energy of the primary particle that initiates the shower. The shower particles can be sampled and detected by an array of particle detectors placed several metres apart on the ground, each detector covering an area of a few square metres.

Figure 1. Integral energy spectrum of primary cosmic rays (from ref. 1).

(The total area covered by the array can, in principle, be as large as desired, say, hundreds or even thousands of square kilometers, although there are practical problems in building very large arrays.) From the measured difference in the arrival times of the shower particles at different locations on the ground, the inclination of the disk axis to the vertical direction can be worked out, thereby giving information on the arrival direction of the primary particle. The energy of the shower-initiating primary particle can be worked out from the measured profile of the density of the shower particles on the ground.

The method of EAS has been employed by various experimental groups to arrive at the spectrum of cosmic rays to extremely high energies, exceeding 10^{20} eV (refs 3–10). The filled circles in Figure 3, for example, represent the so-called UHE (i.e. with energy $E \geq 10^{18}$ eV) cosmic-ray spectrum as measured by one of the experiments, namely, the Fly's Eye experiment⁷. Similar spectra have been obtained by other experiments (see refs 3, 4 for more details). These experiments show that the cosmic-ray spectrum does indeed extend to such high energies (albeit with steeply falling intensity as energy increases) *without any indication of a upper cut-off in energy in the spectrum*, at least up to the highest energy ($E \sim 3 \times 10^{20}$ eV) detected so far for a cosmic-ray particle. This has important implications for possible sources and the underlying acceleration mechanisms responsible for producing these extremely high-energy particles, which we shall discuss in the next two sections. The composition of these extremely high-energy cosmic ray particles is also not well determined. However, recent results of one of the experiments, namely, the Fly's Eye experiment⁷ indicate that the composition is dominated by heavy nuclei (most probably Fe) from energy $E \sim 10^{17}$ eV to $E \sim 5 \times 10^{18}$ eV at which there is a dip in the spectrum accompanied by a change of composition from 'heavy' to 'light' (probably proton, or, possibly even photon).

3. Origin of cosmic rays

The question of origin of cosmic rays consists of two distinct yet interrelated questions: (a) what powers the 'engine' that endows the cosmic-ray particles with the enormous energies that some of them evidently possess? (b) what is (are) the source(s) of these particles? The conventional view is that origin of cosmic rays is linked to some of the most energetic phenomena in the universe represented by active objects like supernova explosions, pulsars, quasars, active galactic nuclei, radio galaxies, and so on. The consensus seems to be that cosmic rays with energy at least up to $\sim 10^{15}$ eV are of galactic origin, i.e. their sources reside within our Galaxy. However, the charged cosmic-ray particles on their way to earth from a given source are repeatedly scattered and

bent by the non-uniform magnetic field of our Galaxy. There is thus, in general, no simple relationship between the arrival direction of the particle at earth and the original direction in which it is ejected from the source. It is, therefore, not possible to trace the source(s) of these cosmic rays to any specific object(s) in the sky. Nevertheless, it is possible to gauge the nature of the potential sources from simple considerations of energetics: The power output of any candidate source must be larger than the power represented by the observed flux of cosmic rays, a rough estimate of the latter being $\sim 10^{34}$ W (see ref. 2 and the references therein). It is widely believed that cosmic rays up to an energy of $\sim 10^{15}$ eV are linked with supernova explosions. The arguments are as follows: A typical supernova explosion releases $\sim 10^{44}$ J of mechanical energy; on the average one supernova explosion occurs in a typical galaxy in about every 30 years (although none has occurred in our own Milky Way since Kepler's supernova of 1604!). Thus the power output in a typical supernova is $\sim 10^{35}$ W. Therefore, a supernova origin of the bulk of cosmic rays requires that roughly about 10% of the energy output of the supernova be used in some kind of acceleration process that boosts low-energy charged particles to the very high energies observed in cosmic rays.

How exactly the acceleration process might work is a subject of considerable complexity and is beyond the scope of this article. Very briefly, essentially all the acceleration mechanisms proposed in this context are variants of a basic idea originally due to Fermi¹¹. In Fermi's original mechanism, charged particles are accelerated by repeated collisions with moving 'magnetized clouds'; the macroscopic kinetic energy stored in the moving clouds is transferred to the particles through their repeated encounters with the clouds. Fermi's basic idea, with some important modifications, has been applied to acceleration of particles in a variety of realistic astrophysical situations, such as acceleration of particles in passing through moving shock waves generated by supernova explosions, acceleration in active galactic nuclei (AGN), in radio galaxies, and so on. A particularly successful mechanism, that is currently favoured by most theoretical cosmic-ray physicists, is the so-called 'diffusive shock acceleration mechanism' (see Drury² for a review and references to original literature). A major characteristic feature of all 'Fermi mechanisms' and, in particular, of the diffusive shock acceleration mechanism (DSAM), is that particles emerge from the acceleration site with spectra that are power-law in energy, like the observed cosmic-ray spectrum. The power-law index (α) of the spectrum is related to basically two characteristic time-scales in the problem, namely the acceleration time scale and the escape time scale, and is, therefore, calculable. The typical values of α in DSAMs satisfy $\alpha \geq 2$.

The DSAM is typically a slow acceleration process; the average energy of any particle increases gradually as the particle crosses the shock region back and forth many times. The particles are confined within the shock region by the magnetic field which, therefore, plays an important role in all variants of the Fermi mechanism. However, for a given strength of the magnetic field and for a given size of the shock region, as a particle's energy increases it becomes increasingly difficult to prevent the particle from escaping from the shock region. This prevents further acceleration of the particle. The process is therefore, self-limiting: For a given strength of the magnetic field (B) and for a given maximum size of the acceleration site (R), there is, in general, a maximum energy, E_{\max} , to which a particle of a given charge and mass can be accelerated. This severely restricts the candidate acceleration sites for the most energetic cosmic rays.

Apart from the slow Fermi acceleration mechanism, several fast or 'one shot' acceleration mechanisms have also been proposed, the chief example of which is acceleration in the induced electric field due to strong rotating magnetic field around pulsars. There are typically two major drawbacks of these kinds of fast acceleration scenarios, viz. (a) a power-law spectrum is not a characteristic feature of these acceleration mechanisms, and (b) the accelerated particles generally lose a lot of their energy in collision with particles of the dense electron-photon plasma that typically surround the high magnetic field regions around objects like pulsars.

The general relationship between the strength of the magnetic field (B) and the characteristic linear dimension of the acceleration region (R) for a variety of astrophysical objects which are suspected to be potential sites of particle acceleration is shown schematically in Figure 2. It is seen that protons or iron nuclei can, in principle, be accelerated to $E \sim 10^{20}$ eV, the most favoured candidate site for acceleration to this energy being the lobes of radio galaxies¹², although active galactic nuclei are also possible sites. Acceleration to energies significantly beyond 10^{20} eV is difficult as we run out of possible known astrophysical objects that would have the right combination of magnetic fields and linear sizes.

When numbers for B , R and the characteristic shock velocity β are put in, it is found that energies up to the 'knee' (i.e. up to energy $\sim 10^{15}$ eV) can be reasonably well achieved by acceleration in shocks associated with supernova remnants (SNRs). For higher energies, SNRs fail, and other sources must be invoked for the rest of the spectrum. As already mentioned in §2, the spectrum beyond $\sim 10^{15}$ eV is steeper than the one below it; it is also dominated by 'heavies' (probably mostly iron nuclei) up to an energy $\sim 5 \times 10^{18}$ eV at which the spectrum becomes flatter and the composition changes to 'light' particles (probably mostly protons). The steep heavy

component beyond the 'knee' and up to $\sim 5 \times 10^{18}$ eV is interpreted as a second galactic component whereas the flatter and 'lighter' component beyond $\sim 5 \times 10^{18}$ eV (i.e. the UHE spectrum) is thought to be of extragalactic origin for the reasons that the gyro-radii of these energetic particles in the galactic magnetic field would be much larger than the size of the Galaxy itself. The heavy galactic component between $\sim 10^{15}$ eV and $\sim 5 \times 10^{18}$ eV is thought to be associated with accelerations in pulsar magnetospheres. This may be because pulsars are thought to be formed in supernova explosions, and so the 'fine-tuning' problem of matching of the two components in terms of their 'amplitude' at the 'knee' may be explained in a natural way. However, the precise way this may come about remains uncertain.

The general view is that UHE component is of extragalactic origin. There are, however, stringent constraints on the distances of the possible sources of these UHE cosmic rays. A proton of energy above $\sim 5 \times 10^{17}$ eV is above the threshold for electron-positron pair creation in collision with photons of the universal 3 K thermal microwave background that is known to pervade the whole universe. Above an energy of $\sim 6 \times 10^{19}$ eV a proton in collision with a microwave background photon is even above the threshold for photo-pion production reaction. Both the above mentioned processes are significant energy-loss processes for any UHE proton propa-

Figure 2. Magnetic field strengths and typical linear dimensions for various astronomical objects, some of which are potential sites for acceleration of cosmic rays. For illustration, the restrictions on the possible astronomical objects that can in principle accelerate protons to 10^{20} eV are indicated. Only objects on, or to the right of, the solid diagonal line can accelerate protons to 10^{20} eV for relativistic characteristic shock velocities ($\beta = 1$). The dotted line marked $\beta = 1/300$ indicates the limit if the shock velocities are only $\sim 1000 \text{ km s}^{-1}$. The applicable restrictions on the possible astronomical objects that can accelerate iron nuclei to 10^{20} eV are also indicated (from Drury²).

gating from an extragalactic source to us. The photo-pion production process is in fact a rather drastic energy-loss process for extragalactic UHE protons; it puts an upper limit to the distance of any extragalactic source from which a proton of a given energy at source can reach us with a given remaining energy. Indeed, soon after the discovery of the 3 K thermal background radiation by Penzias and Wilson in 1965, Greisen, and independently Zatsepin and Kuz'min¹³ suggested in 1966 that the UHE cosmic-ray spectrum, if it is truly extragalactic in origin, should show a cut-off at some high energy somewhere around 10^{20} eV. This predicted cut-off in the UHE cosmic-ray spectrum is now-a-days called the Greisen-Zatsepin-Kuz'min (GZK) cut-off. A similar cut-off is predicted if the UHE particles are heavy nuclei such as iron nuclei; there the relevant process is the photo-disintegration of the nuclei in collision with the 3 K photons.

Whether the measured UHE cosmic-ray spectrum indicates a true GZK cut-off remains unclear. The problem is accentuated by the recent detection of an event with $E \sim 3 \times 10^{20}$ eV by the Fly's Eye experiment^{7,8} and an event with $E \sim 2 \times 10^{20}$ eV by the Akeno experiment^{9,10}. The Haverah Park experiment⁵ as well as the Yakutsk experiment⁶ had also earlier reported events with energy $\sim 1 \times 10^{20}$ eV. It has been recently shown^{14,15} that a proton detected with an energy $\sim 3 \times 10^{20}$ eV could not have come from a source at a distance of more than about 60 Mpc ($1 \text{ Mpc} \approx 3 \times 10^{24} \text{ cm}$). Moreover, at this energy, a charged particle should not be deflected by the intergalactic and the galactic magnetic fields by more than $\sim 10^\circ$ (ref. 14). The implication is that the source of the 3×10^{20} eV event should essentially lie within a distance of about 60 Mpc from us and it should be within a cone of angular radius $\sim 10^\circ$ centered around the measured arrival direction of the event. Yet, when a source-search for this event was made in the sky^{14,15}, no potential source such as any active galactic nucleus, radio galaxy, etc. satisfying the above restrictions on the distance and positional direction was found! The highest-energy cosmic ray event, therefore, constitutes a puzzle: Here we have a particle so energetic that its essentially undeflected trajectory should allow us to more or less directly trace its sources back in the sky (unlike the case for lower energy particles which suffer random deflections due to the magnetic fields enroute). However, no suitable source is found when the trajectory is traced back!

In the next section we discuss the possibility that the highest-energy cosmic rays (HECR), i.e. the cosmic rays with energies above 10^{20} eV constitute a new component perhaps of an entirely different origin. It is even possible that the HECR particles are not connected with any acceleration process associated with any known astrophysical object, an exciting possibility that has received

a great deal of attention in recent years and to which we now turn.

4. The highest-energy cosmic rays: Possible non-acceleration origin

The existence of the HECR poses serious challenge for conventional DSAM that attempts to explain the origin of these particles in terms of accelerating them in special astrophysical situations, e.g. in relativistic shocks associated with AGNs, or in the lobes of radio galaxies. Acceleration in the latter is in principle capable of producing particles with energies as high as a few times 10^{20} eV although it requires the use of rather extreme (and perhaps somewhat unrealistic) values of parameters such as R , B , etc.

One alternative possibility is that the HECR particles have a more *fundamental* origin in the sense that they are *not accelerated* at all^{14,16-18}. Instead, these particles may simply be the decay products of some sufficiently massive elementary particle species surviving from an early cosmological epoch. One attractive realization of this idea of *non-acceleration* origin^{16,17} of HECR involves collapse and/or annihilation, in recent epochs, of cosmic topological defects (TDs)¹⁹ such as magnetic monopoles, cosmic strings, domain walls, etc., which could be formed in the early universe during phase transitions associated with spontaneous breaking of symmetries implemented in unified models of elementary particle interactions such as in Grand Unified Theories (GUTs).

Owing to their topological stability, the TDs formed in the early universe can survive down to the present epoch. The TDs nevertheless are occasionally, and in certain circumstances, frequently, destroyed in physical processes like collapse or annihilation (see ref. 16 and references therein). When a TD is physically destroyed, the energy stored in the TD is released in the form of massive quanta of the fields that 'constitute' the TD, namely, the massive gauge and higgs fields (the 'X' particles) associated with the broken symmetry. The released X particles would then decay, essentially instantaneously, typically into fundamental particles like quarks and leptons. Hadronization of the quarks would then produce jets of hadrons containing mainly light mesons (pions) together with a small fraction ($\sim 3\%$) of nucleons (protons and neutrons). The γ -rays and neutrinos from the decay of the neutral and charged pions, respectively, would thus be the most abundant particles in the final decay products of the massive X particles. If the TDs under consideration were originally formed at a GUT energy scale, the mass m_X of X particles released from the TDs can be $\sim 10^{25}$ eV. The decay of the X particles released from the TDs can thus give rise to protons, neutrons, γ -rays and neutrinos

with energies up to $\sim m_X$, very much higher than what can be achieved by astrophysical shock acceleration mechanisms. The cosmic ray particles can thus be produced directly in this scenario (referred to as 'TD model'), and no acceleration mechanism is needed.

The release of X particles from TDs may occur continually at all cosmological epochs after the formation of the TDs under consideration in the early universe. However, only the X particles released in relatively recent epochs are likely, if at all, to contribute to the present-day flux of UHE protons and γ -rays, because those released in the earlier epochs would have to traverse greater distances through the cosmic background radiation fields to reach us and would, therefore, lose significant fractions of their energy in collision with the photons of the background radiation. However, neutrinos can come from relatively earlier cosmological epochs because they suffer little energy loss as a consequence of their small cross section of interaction with the relevant particles of the background medium.

In the TD model, the shapes of the energy spectra of protons, γ -rays and neutrinos at production (i.e. the injection spectra) at any time are determined primarily by the physics of fragmentation of quarks into hadrons and not by any astrophysical parameters. At any given time, the injection spectra are, therefore, also independent of the specific kind of TDs responsible for release of X particles. Different kinds of TDs, however, evolve in different ways. Therefore, the absolute magnitude and the rate of production of the various particles, and so also the final evolved spectra, will be different for different kinds of TDs. However, in the highest energy regions, the shapes of the proton as well as γ -ray spectra become insensitive to the kind of TDs producing them, because to survive at these energies, the protons and photons must originate at relatively close (i.e. non-cosmological) distances for which the cosmological evolution is immaterial. The shape of the neutrino spectrum will, however, remain sensitive to the kind of TDs producing them and their cosmological evolution because neutrinos can propagate over large (cosmological) distance scales without much attenuation.

The injection spectra of nucleons, γ -rays, and neutrinos in the TD model have been calculated^{16,17,20} by extrapolating the available models of hadronization of quarks as described by the theory of Quantum Chromo-Dynamics (QCD) to extremely high energies. This gives approximately power-law differential injection spectra for nucleons, γ -rays and neutrinos all with a power-law index $\alpha \sim 1.3$. However, there is a great deal of uncertainty involved in extrapolating the low-energy QCD-based models of hadronization of quarks to extremely high energies involved in the present situation. It is also possible that the value of α for nucleons may be somewhat different from that for, say, γ -rays. The main

point, however, is that the injection spectra of cosmic ray particles in the TD model can, in principle, be considerably *flatter* than in the standard shock acceleration scenarios which, by and large, produce differential injection spectra with $\alpha \geq 2$.

The typical shapes of the final proton, γ -ray and neutrino spectra, including the effects due to propagation through the extragalactic medium, are shown in Figure 3. This figure was obtained for a specific TD model, namely, that involving annihilation of magnetic monopole-antimonopole pairs²¹; however, as explained above, the spectra have more or less a universal shape independent of the specific kind of TD-process one considers, especially at the highest energies, and hence the spectra shown in Figure 3 are representative of the particle spectra expected in TD models in general. One major uncertainty in this scenario is the absolute magnitude of the cosmic ray flux produced by TDs, i.e. the 'normalization' of the predicted flux. This clearly depends on the specific process of particle production involving specific kind of TDs. The normalization of the particle fluxes in Figure 3 implies a monopole abundance that is well below the stringent astrophysical

Figure 3. The proton (solid line), γ -ray (long-dashed line) and the neutrino (short-dashed line) spectra in the TD model including the effect of propagation through the cosmic background medium. The X particle mass is taken to be 10^{15} GeV and an extrapolation of QCD-based hadronization spectrum to the relevant high energies has been used to obtain the injection spectra. The combined proton and gamma ray flux has been normalized at $10^{19.7}$ eV to the 'extragalactic flux component' (thin solid line) (see ref. 7) fitted to the data from the Fly's Eye experiment (filled circles with error bars)⁷. Also shown (dash-dotted line) is an approximate limit on the neutrino flux determined from non-detection of deeply penetrating particles by the Fly's Eye detector.

upper limit on the monopole abundance – the so-called ‘Parker limit’ (see ref. 22) – and is, therefore, quite plausible.

From Figure 3 we see that TD models are probably not relevant for cosmic rays below about 5×10^{19} eV; it is only at energies above this energy that TD models become a viable option. It is to be mentioned here that the shape of the proton spectra in the acceleration models (not shown in Figure 3), which typically yield power-law injection spectra with index $\alpha \geq 2$, would correspond to a sharply falling curve at energies beyond $\sim 10^{20}$ eV, and so would be unable to explain the two highest energy events indicated in the figure. The ‘dip’ of the proton curve of Figure 3 beginning at $\sim 10^{20}$ eV and its subsequent ‘recovery’ at $\sim 10^{21}$ eV are characteristic features induced by the propagation effects (the GZK effect discussed in §3). The ‘recovery’ after the ‘GZK cut-off’ of the proton spectrum in Figure 3 is, however, a feature that is not shared by the proton spectra one gets in standard acceleration models, which as mentioned above, do not ‘recover’ after the GZK cut-off. (For detailed understanding of this point see, e.g. figure 1 of ref. 17.) The recovery in the present case is essentially due to flatter nature of the proton injection spectrum in the TD model compared to that in the acceleration models. Note also from Figure 3 that the two highest-energy events are naturally explained in the TD model only if these are γ -ray events, and not protons. Experimentally, it is hard to determine the composition of the events at these energies with full certainty. Although, the traditionally favoured composition for these events are protons, a γ -ray composition is certainly not ruled out⁸.

Figure 3 also indicates a peculiar feature of the present HECR data: There is an apparent ‘gap’ in the spectrum; the two highest-energy events are separated from the rest of the data by almost half a decade in energy. Possible implications of this apparent ‘gap’ in the spectrum for theories of origin of HECR have recently been analysed¹⁸ where it is concluded that although an acceleration origin of the HECR cannot be entirely ruled out with the current data statistics, the persistence of the apparent gap in the existing data at a quadrupled total exposure of the detector (as might be expected to be achieved within the coming few years) would rule out many acceleration models at more than 99% confidence level. In that case, one may have to take recourse to some kind of non-acceleration scenario for the origin of HECR like the TD model described above.

Besides the characteristic shapes of the HECR spectra, the TD models of HECR origin have two definitive predictions. Firstly, the HECR should consist of only ‘fundamental’ particles like protons, neutrons, γ -rays, neutrinos, electrons, positrons, and so on (and perhaps their antiparticles too), but definitely *no nuclei* such as ${}^4\text{He}$ or Fe. (There is no way hadronization of quarks

would directly give rise to nuclei!) Secondly, the HECR should be highly rich in γ -rays and neutrinos. These predictions can be used as crucial tests of the TD model in future HECR experiments with large-area detector coverage, such as the proposed Pierre Auger project²³. More details on the subject of topological defect scenario of origin of HECR can be found in refs 24, 25.

5. Summary and conclusions

We have discussed rather sketchily the present status of the subject of cosmic rays, the origin of which is one of the major unsolved problems in physics and astrophysics. There are reasons to believe that cosmic rays with energy up to the ‘knee’ region of the spectrum corresponding to the energy $\sim 10^{15}$ eV are produced by some kind of acceleration process operating in the relativistic shocks associated with supernovae, and those from about 10^{15} eV up to the ‘ankle’ region at $\sim 5 \times 10^{18}$ eV are produced by acceleration processes in pulsar magnetospheres. The sources of these components are thought to lie within our Milky Way Galaxy, although the highly tangled nature of the trajectories of these particles (caused by the non-uniform galactic magnetic field) prevents direct identification of these sources with the known supernova remnants and pulsars. The component beyond $\sim 5 \times 10^{18}$ eV is thought to be of extragalactic origin. As far as the highest-energy cosmic rays (i.e. those with energy above $\sim 10^{20}$ eV) are concerned, the known acceleration processes are found to be inadequate from the point of view of energetics. We have discussed a possible alternative *non-acceleration* scenario for the origin of this HECR component. This scenario involves new physics; in particular, it involves formation and destruction of cosmic topological defects in the form of cosmic strings, monopoles, etc. that are predicted in theories of early universe that bring together modern ideas of high-energy particle physics and the big-bang model of cosmology. The highest-energy end of the cosmic ray spectrum thus offers a probing ground for testing some of these new ideas.

We have skipped many issues that have important bearings on the question of origin of cosmic rays in general, such as the issue of isotropy of the observed cosmic rays, the possible important roles of γ -ray astronomy as well as neutrino astronomy in unravelling the mystery of cosmic rays, and so on. It is hoped, however, that the reader will get a general flavour of the outstanding open issues in modern cosmic ray physics, issues which undoubtedly constitute one of the most exciting areas of current research in contemporary physics, astronomy and astrophysics.

Is the Hubble flow a result of inverse cascade?*

V. Krishan

Indian Institute of Astrophysics, Bangalore 560 034, India

A few general characteristics of nonlinear open systems are described. A turbulent fluid is one such system which exhibits order by supporting structures in an otherwise random medium through the transfer of energy from small spatial scales to large spatial scales. The spatial distribution of energy so derived is found to account well for two disparate situations like the solar granulation and the rotation curves of galaxies. Encouraged by these successes, one wonders if the spatial distribution of energy at the largest scales, i.e. $V(L) \propto L$ has anything to do with the Hubble flow.

COHERENT structures, correlated motions and well-defined patterns are observed on a variety of spatial as well as temporal scales. Organized states of matter and motion can be seen in a convection cell, cloud complexes, a tornado, a cyclone, zonal flows on planetary surfaces, the Red Spot of Jupiter, convective flows on stellar surfaces, spiral patterns in galaxies, clusters of galaxies and perhaps ourselves. Figure 1 a-c represents distribution of clouds in the earth's atmosphere, of convective

motions on the solar surface and of galaxies in clusters of galaxies. Could you tell one from the other? Figure 2 a, b represents the velocity vectors in a cluster of galaxies and on the solar photosphere. Both show converging and diverging flows. The usual interpretation for clusters of galaxies is infall of matter in the strong gravitational field of the unseen dark matter, whereas the solar photosphere acquires the same pattern due to the formation of fluid vortices. Can the vortices account for the flow patterns in clusters of galaxies? Is the invisible matter indispensable? In other words, do these organized states of matter and motion arise under equilibrium or non-equilibrium conditions? Is it substance and or style? Are these dissipative structures?

Our proposal¹⁻⁶ is that apparently disparate phenomena of (i) non-equilibrium motions on stellar surfaces, (ii) the large scale organization of matter, motion and magnetic field or in general the large scale structure of the universe have their origin in the inverse cascade of energy leading to self-organization in an otherwise nonlinear turbulent medium.

Novelties of non-equilibrium systems

Near equilibrium, a system, when perturbed, comes back

*Talk presented at the Symposium on 'Interface of Astronomy with other Sciences', organized by Indian National Science Academy and held at the Indian Institute of Astrophysics Observatory, Kodaikanal, on 4-5 May 1995.

to its initial state and is said to be stable. Under far-from equilibrium conditions, a system, when driven sufficiently far, may never return to its initial state and is said to be unstable. The system undergoes a bifurcation, where the initial solution becomes unstable and the new state behaves in a manner completely different from that of the initial state. The new state that emerges after a bifurcation is known as a dissipative structure. A spectacular example of this phenomenon is provided by

Figure 1a-c. Distribution of clouds in the earth's atmosphere of convective motions on the solar surface and of galaxies in clusters of galaxies.

chemical clocks. A bifurcation is associated with the breaking of a symmetry. One starts with a system describable by completely symmetric equations and finds their solutions which are not symmetric, i.e. a bifurcation splits into a so-called right handed and a left handed solution. The physical reality may be embedded in only one of these solutions. For example, sea shells usually have a preferential chirality. It is seen that in a highly unstable dynamical system, the trajectories starting from infinitesimally close points diverge exponentially in time and such a system is said to be in a chaotic state. Thus a completely deterministic description supports a chaotic solution, which lends it a probabilistic behaviour, i.e. the system is intrinsically random and irreversible. For example, a collection of particles moving parallel to each other, develops randomness with the passage of time, i.e. they try to reach equilibrium. Now time inversion symmetry requires that the reverse must happen, i.e. randomly directed velocity vectors must align themselves with the passage of time. But this is never observed (Figure 3). This means that we need representations of dynamics which are not invariant with respect to time inversion and such representations do exist for highly unstable systems. This reduces the predictability of a system. Tomorrow is not already present in today! Instead, it emerges in an unpredictable way, the way improvization is achieved in Indian music.

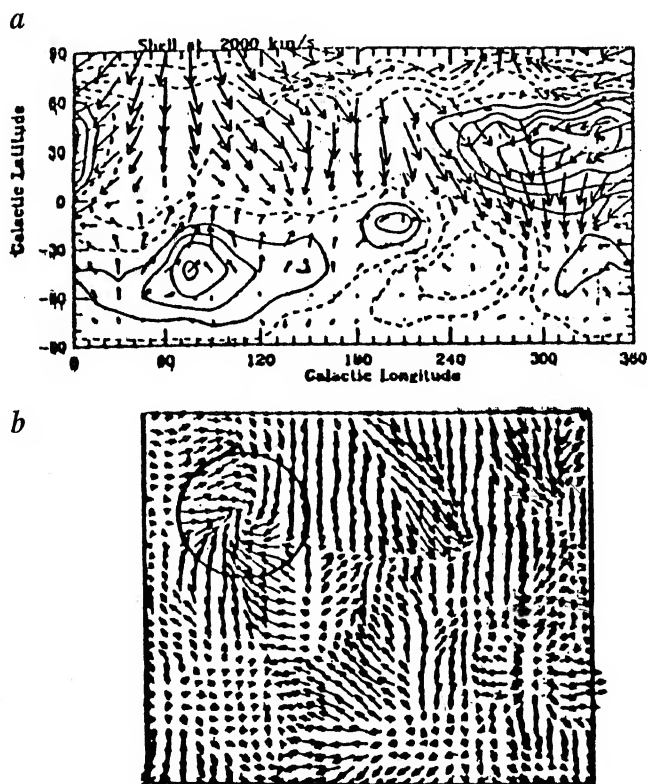

Figure 2. Velocity vectors in a cluster of galaxies and on the solar surface.

It is in intrinsically random, irreversible, unsymmetric, non-equilibrium systems that all phenomena of material existence are embedded. The conditions for formation of dissipative structures can therefore be summarized as^{7,8}: (i) a macroscopic system far from equilibrium, so that it can develop correlations among its different parts, (ii) the system is open towards its environment, i.e. it can draw from its surroundings, and (iii) it should be able to self-reinforce itself autocatalytically by a sustained level of fluctuations deriving from its neighbourhood.

Fluid turbulence

Far from equilibrium conditions exist everywhere in the universe, including its origin, the big bang. Many structures like galaxies and clusters of galaxies are suggested to form and exist in non-equilibrium states. The belief in equilibrium has led us to darkness, since, equilibrium commands that most of the matter in the universe remain invisible. To investigate the role of non-equilibrium nonlinear processes in astrophysical objects, we need to go to the fluid description since several aspects of stellar, galactic and the universe as a whole can be understood by treating them as fluids, always in a state of turbulence. The fluid turbulence is a tricky subject. Even Heisenberg found the problem too difficult. He is reputed to have said that he hoped, before he dies, some one would explain quantum mechanics to him, but after he died, he hoped, God would explain turbulence to him⁹. Nevertheless, a few characteristics of fluid turbulence can be summarized here. It is a random state of fluid motion that supports several interacting length and time scales through the excitation of instabilities. The scales are constrained by boundaries, buoyancy and dissipation. Turbulence affects all transport and diffusion

processes, generally leading to an enhanced efficiency.

Quantification of turbulence

Mean values of the products of field variables (like velocity U , magnetic field, etc.) and their derivatives form the fabric of a turbulent medium. Out of these, the two-point correlation function $R_{ij}(\mathbf{r})$ defined as

$$R_{ij}(\mathbf{r}) = \langle U_i(\mathbf{X}) U_j(\mathbf{X} + \mathbf{r}) \rangle \quad (1)$$

is the most important. Here, the angular brackets represent the space average. For homogeneous and stationary turbulence $R_{ij}(\mathbf{r})$ depends only on the configuration and not on its location. The Fourier transform $\phi_{ij}(\mathbf{K})$ of $R_{ij}(\mathbf{r})$ is defined as:

$$\phi_{ij}(\mathbf{K}) = \frac{1}{(2\pi)^3} \int R_{ij}(\mathbf{r}) e^{-i\mathbf{K}\cdot\mathbf{r}} d^3r. \quad (2)$$

The total kinetic energy W per unit mass of the fluid is given by

$$W = \frac{1}{2} \langle U_i(\mathbf{X}) U_i(\mathbf{X}) \rangle = \frac{1}{2} \int \phi_{ii}(\mathbf{K}) d^3K = \int E(K) dK, \quad (3)$$

where $E(K)$ is the omnidirectional energy spectrum. From the Kolmogorov law, that in a quasi-steady state, there should be a stationary flow of energy in K space from the source to the sink, i.e. the energy density flow rate should be a constant and equal to the dissipation rate E of the energy density at the sink, one finds the energy spectrum

$$E(K) \sim \varepsilon^{2/3} K^{-5/3} \quad (4)$$

describing the flow of energy from large spatial scales to small spatial scales. But what if the assumptions of homogeneity and isotropy are dropped?

Inverse cascade in 2D turbulence

In a 2D incompressible and ideal system, there are two invariants, the total energy W and the enstrophy U_E defined as:

$$U_E = \int \frac{(\nabla \times \mathbf{U})^2}{2} d^3r. \quad (5)$$

Therefore one derives two types of inertial ranges, one for the energy and the other for the enstrophy. The two energy spectra are:

$$E(K) \sim \varepsilon^{2/3} K^{-3} \quad \text{for enstrophy} \quad (6)$$

and $E(K) \sim \varepsilon^{2/3} K^{-5/3}$ for energy and it has been argued

Figure 3. Irreversible processes.

and demonstrated that energy cascades from small spatial scales to large spatial scales according to $K^{-5/3}$ law, thus setting up an inverse cascade¹⁰.

Inverse cascade in 3D turbulence

The appearance of large scale structures in the 3D atmospheres of planets compels us to look for the possibility of inverse cascade in 3D systems. Specifically, the observations of helical type of flow structures in circumstances varying from oceans to cloud complexes, brought to the fore, the importance of helicity in turbulent fluids. The fundamental idea that needed to be appreciated was that the large helicity fluctuations always exist in a turbulent medium, even if the average helicity vanishes. It was shown that the fluctuating topology of the vorticity field in turbulent flows can be characterized by the statistical helicity invariant I represented by conserved mean square helicity¹¹⁻¹³:

$$I = \int \langle h(\mathbf{X}) h(\mathbf{X} + \mathbf{r}) \rangle d^3r, \quad (7)$$

where

$$h = \mathbf{U} \cdot \nabla \times \mathbf{U}.$$

Thus E and I are the two invariants of a helically turbulent 3D system. Again using Kolmogorovic arguments for the I invariant, one finds the spectrum in the inertial range as

$$E(K) \propto K^{-1}$$

and the total energy density

$$W = \int E(K) dK \propto \log [L(t)/l]. \quad (8)$$

Here $L(t)$ is the transient length scale excited at time t . One observes that the energy grows very slowly as the spatial scale $L(t)$ grows. So, practically, there is little transfer of energy towards large scales. But, what happens is that as the correlation length of helicity fluctuations increases, the velocity and vorticity become more and more aligned and as a consequence the non-linear term $(\mathbf{V} \cdot \nabla)\mathbf{V}$ of the Navier-Stokes equation decreases and flow of energy towards small scales is retarded. On the other hand, the growth of correlation length cannot go on indefinitely. Especially if the medium is restricted in the vertical direction by gravity or buoyancy as is true of atmospheres of any celestial object, may it be a planet or a star. Under such circumstances, the correlation length continues to grow in the horizontal plane and the system becomes more and more anisotropic. In addition, $I(K)$ is found to be

dominant at small K while $E(K)$ is larger at large K and the inverse cascade of I follows.

What is achieved by the growth of correlation length of helicity fluctuations is the anisotropy in the system which can now be approximated to a quasi 2D system. Here, the horizontal scale is much larger than the vertical scale and the vertical velocity is smaller than the horizontal velocity. Under these conditions, the energy and the I spectrum become identical and go as $K^{-5/3}$, as in the 2D case. One expects that an increasing fraction of energy is transferred to large spatial scales as the anisotropy in the system increases. This can go on until coriolis force begins to be effective. The length scale L_c where the nonlinear term of the Navier-Stokes equation becomes comparable to the coriolis force is given by $L_c = U/\Omega$, where Ω is the angular velocity. At these large scales, the system simulates 2D behaviour and enstrophy conservation begins to play its role. One may consider scales $L \geq L_c$ as a source of vorticity injection into the system. The enstrophy then cascades towards small scales with a power law spectrum given by:

$$E(K) \propto K^{-3}$$

$$W \propto L^2. \quad (9)$$

Thus the complete energy spectrum of a hydrodynamic turbulent medium is given in Figure 4. What is the evidence for this spectrum?

Solar granulation

The cellular velocity patterns observed on the solar surface are believed to be manifestations of convective phenomena occurring in the sub-photospheric layers. The quality observations obtained at Pic-du-Midi indicate the existence of a continuum of sizes instead of one or two

Figure 4. Turbulent energy spectrum, L_z , normalizing length; L_c , break due to coriolis force (Krishan^{1,2}).

dominant scales in the solar granulation. We have proposed an inverse cascade model for the entire granulation phenomenon. It is encouraging to find that the energy spectrum of granular motions deduced from observations does show a branch with $K^{-5/3}$ which turns into a $K^{-0.7}$ law towards small K (Figure 5). This agrees fairly well with the predictions of the inverse cascade model where the Kolmogorov branch $K^{-5/3}$ develops into a K^{-1} behaviour towards large spatial scales. Thus the solar granulation provides one example where the flat branch K^{-1} seems to account well for an observed phenomenon. Is there another example?

Figure 5. Power spectrum of the solar photospheric motions (Zahn¹⁵).

Rotation curves of galaxies

The issue of the flat rotation curves of galaxies and the need for dark matter is described precisely in Figure 6. The flat nature of the orbital motion in galaxies is accounted through the relationship $\frac{1}{2} mV^2 = (GMm/R)$ by assuming that $M \propto R$ and therefore, the velocity $V = \text{constant}$. Since the mass $M \propto R$ has no luminosity associated with it, it is known as dark matter. We present an alternative explanation for the flat nature of the velocity by applying the ideas of inverse cascade in a turbulent atmosphere of a galaxy. We propose a law of velocities of the following type:

$$V(L) = AL + BL^{1/3}$$

in the inner region, i.e. for $L < L_z$ and (10)

$$V(L) = CL^{-1/2} + D[\ln L/L_z]^{1/2}$$

in the outer region, i.e. for $L > L_z$ of a galaxy. A, B, C and D are determined from the fits with the observed velocity curves. We have successfully accounted for the flat nature of the rotation curves for nearly hundred galaxies. An example is given in Figure 7.

We have discussed two cases, from completely disparate phenomena, where the Kolmogorov branch $K^{-5/3}$ and the flat branch K^{-1} together have explained the observed behaviour very well. What about the rest of the spectrum given in Figure 4? Particularly, is there any evidence for the spectrum at the largest spatial scales, i.e. for $E(K) \propto K^{-3}$ or $W(L) \propto L^2$?

Figure 6. The case for dark matter in spiral galaxies. *Left*: The orbital velocities of the planets (dots) decrease with distance from the Sun exactly as predicted by Newtonian gravitation (line), assuming a system dominated by one solar mass at its center. *Right*: The cosmos is not as well behaved on galactic scales. Here a graph of orbital velocity versus radius has been computed for NGC 3198, a spiral galaxy in Ursa Major, assuming that the distribution of light serves as a good indicator of the distribution of mass. The failure of the observed velocities (dots) to match the predicted ones is striking and points to an unseen component of dark matter in the galaxy.

Figure 7. Flat rotation curve of a galaxy fitted by equation (10).

The Hubble flow

The energy spectrum at the largest spatial scales is governed by enstrophy transfer and goes as

$$E(K) \propto K^{-3}. \quad (11)$$

Putting in the proportionality constants, the total energy density per unit gram varies as

$$W(L) = V^2(L) \simeq (\varepsilon/L_c^2)^{2/3} L^2$$

or

$$V(L) \simeq (\varepsilon/L_c^2)^{1/3} L. \quad (12)$$

$\varepsilon = V^2/\tau$ is the energy injection rate and (ε/L_c^2) is the enstrophy injection rate. Substituting for L_c , the scale at which the coriolis force becomes comparable to nonlinear inertial force, one finds

$$V(L) \simeq (\Omega^2/\tau)^{1/3} L \quad (13)$$

which, when compared with the Hubble flow expressed as

$$V = HL$$

gives the value of the Hubble constant H to be

$$H = (\Omega^2/\tau)^{1/3}. \quad (14)$$

Does this mean that the velocities with which the galaxies are receding from each other like dots on an expanding balloon are given by the largest spatial scale end of the same energy spectrum whose small spatial scale part accounts so very well for the flat rotation curves? If one assumes that the angular speed at scales $\sim L_c$ is such that $\Omega^{-1} = \tau$, then one gets $H^{-1} = \text{age of the universe} = \tau$, the duration for the injection of energy. If stars are the main contributors to turbulence, the age of the universe τ is nothing but the age of the oldest stars. Of course, the big bang itself is a source of turbulence in the universe.

Conclusion

The need of the hour is to think non-equilibrium. This may alleviate some of the caveats that arise from the belief that equilibrium rules the universe. Hydrodynamics in addition to gravitational processes must be included in the scheme of things since a self-consistent distribution of matter and motion must be determined. One must realize that converging flows commonly occur in a turbulent fluid without the necessity of invoking great masses. The whole question of mass distribution or the large scale structure of the universe can only be settled by including the physics of hydrodynamical processes in the making of structures. The angular momentum must be treated with reverence!

New measurements of the Hubble constant and its implications*

D. C. V. Mallik

Indian Institute of Astrophysics, Bangalore 560 034, India

One of the key projects on the Hubble Space Telescope (HST) is to determine the distance to the Virgo cluster of galaxies using classical Cepheid variables as standard candles. The refurbished HST has resolved and measured the periods and magnitudes of twenty odd Cepheids in M100, a spiral galaxy near the core of the Virgo cluster. Coincidentally, ground-based observations from Hawaii with the help of a high resolution camera, under subarcsecond seeing conditions, have also succeeded in the identification of a few Cepheids in NGC 4571, another Virgo spiral. The distance to the Virgo cluster from these two sets of measurements turns out to be 17.1 ± 1.8 Mpc and 14.9 ± 1.2 Mpc respectively and implies a value of the Hubble Constant H_0 equal to 80 ± 17 km s⁻¹ Mpc⁻¹ and 87 ± 7 km s⁻¹ Mpc⁻¹. The result implies that the age of the Universe is in the neighbourhood of 10 ± 2 Gyr. Some of the globular clusters in the Milky Way system are known to be older (age ~ 14–18 Gyr) from stellar evolutionary calculations. Secondly, another important standard candle, the Type Ia supernova, has now been accurately calibrated using HST data on Cepheids in IC 4182 and NGC 5253, the host galaxies for SN 1937C and SN 1972E respectively. These calibrations yield a much lower value of H_0 from the Hubble diagram of SNe Ia.

Though there may still be uncertainties of the order of 10–20% in the measurements, the low value of H_0 from SN Ia measurements focuses attention on the class of objects classified as SN Ia, and their suitability as standard candles. Significantly, the high value of H_0 from the measurements of classical Cepheids may indicate that we live in a Universe somewhat different from the one we have been thinking we do.

Ever since Hubble's discovery of the universal recession of galaxies as a result of the cosmological expansion, measurement of the rate of this expansion, that is its current value has been a subject of intense investigation. The Hubble parameter H_0 , referred to as the Hubble Constant is related to the factor $R(t)$ which determines the rate of the isotropic expansion of a homogeneous Universe through the relation

$$H_0 = \dot{R}/R. \quad (1)$$

H_0 is an observationally determinable parameter as it

*Based on a talk presented at the Symposium on 'Interface of Astronomy with other Sciences', organized by Indian National Science Academy and held at the Indian Institute of Astrophysics Observatory, Kodaikanal, on 4–5 May 1995.

appears in the velocity–distance relation of receding galaxies given by

$$V_r = H_0 \times D. \quad (2)$$

Here V_r is the velocity of recession usually measured as a redshift of the spectral lines from distant galaxies and D is the distance to the galaxies. As velocities are measured in km s⁻¹ and the distances in megaparsecs (1 parsec = 3.085×10^{13} km) H_0 is usually expressed in the units of km s⁻¹ Mpc⁻¹ and has the dimension of inverse time. The reciprocal of H_0 is the age of the Universe. In the present century, measurement of H_0 has been one of the most important goals of observational astronomy.

To derive H_0 two measurements are needed, the velocity of recession of a faraway galaxy and its distance. Though the velocities are estimated quite accurately from the redshift of the spectral lines, distances to astronomical objects are difficult to determine. And it is the uncertainty in the distance estimates that has hindered an accurate determination of H_0 since the 1930s. Hubble's original estimate of 500 km s⁻¹ Mpc⁻¹ for H_0 (ref. 1) was revised to about 250 km s⁻¹ Mpc⁻¹ by Baade² when he recognized the population differences between classical Cepheid and RR Lyrae variables and revised the luminosities of the former upward by 1^m.5. A further revision to $H_0 = 75$ km s⁻¹ Mpc⁻¹ was effected by Sandage³ when he discovered that on the photographic plates objects, thought earlier to be the brightest stars in distant galaxies were, in fact, small clusters of stars or compact knots of ionized hydrogen regions around these clusters. Since the 1960s the estimated values of H_0 have ranged between 50 km s⁻¹ Mpc⁻¹ and 100 km s⁻¹ Mpc⁻¹, creating an uncomfortably large range of a factor of two in the inferred size and age of the Universe. A curious feature of these estimates is that the value of H_0 shows a bimodal distribution with peaks at approximately 50 and 90 km s⁻¹ Mpc⁻¹ which is directly related to the two widely different values of the distance to the Virgo cluster obtained by the use of methods falling in two mutually exclusive categories. The 'short' distance to Virgo ($D \sim 15$ Mpc) leads to the larger value of H_0 while the 'long' distance to Virgo leads to an H_0 in the neighbourhood of 50 km s⁻¹ Mpc⁻¹. Each is supported by measurements involving secondary distance calibrators. Although almost all these methods yield consistent results in the Local Group and beyond, they seem to suddenly

fall out with one another at the nearest cosmologically significant distance, that is the distance to the Virgo cluster.

Galaxies are known to cluster on various scales. The Local Group of twenty odd galaxies, which the Milky Way is a member of, is part of a larger group, the Local Supercluster containing within it several groups and clusters including the Virgo cluster. Within the group, galaxies evince a complex pattern of motion that has little to do with the uniform Hubble flow. Thus to obtain an estimate of H_0 astronomers have to look at clusters of galaxies at distances large enough that the random motions of the galaxies within the group are a tiny fraction of their recessional motion as part of the uniform Hubble flow. Since direct trigonometric methods do not carry us far enough even within the Milky Way, astronomers have always relied heavily on indirect methods to estimate distances to faraway objects. Using direct trigonometric methods to obtain distances and hence the luminosities of bright stars, they have extended distance estimates to remote regions of the Galaxy and nearby galaxies using the bright stars as the standard candles. At distances where the bright stars are too faint to be seen, secondary standard candles like globular clusters, SN Ia, HII regions, etc. have been devised and used to estimate distances. Farther out a tertiary standard candle like the brightest galaxy, or the largest galaxy, in a cluster has been used and eventually large enough distances are reached where the unperturbed uniform expansion can be clearly discerned. A velocity estimate at this distance obtained from the redshift of the spectral lines of the test object then leads to H_0 . This stepwise process, wherein new distance indicators are calibrated using indicators from the previous step, is liable to accrue both random and systematic errors lending a large uncertainty in the value of H_0 that is eventually estimated. Elimination of a step in the process could improve the accuracy of the distance determination considerably and ways and means of effecting this have occupied the attention of astronomers.

Direct measurement of magnitudes and periods of classical Cepheid variables in the Virgo cluster was long recognized to be a potentially powerful way that leapt over a crucial step in the cosmological distance ladder by eliminating the need of secondary calibrators to obtain the distance to this cluster. The use of Cepheids involves only one step – the calibration of their period–luminosity relation by direct trigonometric means, known since the days of Harlow Shapley. Since the Earth's atmosphere hampers attempts at resolving Cepheid variables at the distance of the Virgo cluster, the need for observations from a satellite-based telescope was recognized. The Hubble Space Telescope (HST) has now performed this task by resolving a large number of classical Cepheids in the spiral galaxy M100, a member

of the Virgo cluster. Near-simultaneous advances in optical and detector technologies have enabled astronomers to beat the 'seeing' to a large extent and using a high resolution camera at the Canada–France–Hawaii Telescope (CFHT) atop Mauna Kea, Hawaii, a group has been able to resolve a handful of the brightest classical Cepheids in NGC 4571, another member spiral of the Virgo cluster. The distance estimates to both the spirals, whose positions in the sky are close to the assumed dynamical centre of the cluster, support the long distance scale, implying a value of H_0 close to $80 \text{ km s}^{-1} \text{ Mpc}^{-1}$. This direct distance estimate to the Virgo cluster suggests a Universe no older than 12 Gyr.

Such a young Universe is bothersome since stellar astronomers have gathered ample evidence of stars and clusters of stars in our Galaxy which appear to be older. Are all stellar age estimates then wrong? A second equally important problem has been thrown up by measurements from the very same HST, this time of supernovae of Type Ia. While these supernovae are only secondary distance indicators, their luminosities have now been directly calibrated by using classical Cepheid variables in the galaxies NGC 5253 and IC 4182 where the prototype SNe Ia 1972E and 1937C were observed. Using SN Ia as a standard candle one obtains quite a different value of H_0 , namely $H_0 = 52 \text{ km s}^{-1} \text{ Mpc}^{-1}$ which is in full agreement with the 'long' distance scale and hence an older Universe. Finally, a value of H_0 in the neighbourhood of $80 \text{ km s}^{-1} \text{ Mpc}^{-1}$ will rule out any preferred cosmological model with the density parameter $\Omega_0 = 1$ unless the cosmological constant is nonzero.

Classical Cepheids as primary distance indicators in an expanding Universe

Although classical Cepheid variables had been known since the late eighteenth century, their prime importance as distance indicators was first realized in the 1910s when Henrietta Leavitt published the results of her study of these stars in the Small Magellanic Cloud (SMC). Leavitt noticed that in the SMC the Cepheid variables with longer periods had higher average apparent brightness. Since all stars in the SMC were logically at about the same distance from us, it was immediately obvious that Leavitt's correlation implied the existence of a period–luminosity (P–L) relation for these variables. The significance of this discovery was realized soon by Harlow Shapley then working at Mt. Wilson, California. Shapley used the method of statistical parallaxes on a handful of Galactic Cepheids, for which proper motion data were available, to obtain a calibrated P–L relation. Shapley had noticed that the globular clusters invariably contained short period variables called the RR Lyrae variables whose light curves were no different from those of the classical Cepheids. He extended the P–L

relation to include the RR Lyrae variables obtaining thereby their intrinsic luminosities. His next step was to use these variables to obtain the distances to globular clusters and then to map their distribution as part of our galactic system. The sequence of discoveries by Shapley which finally gave a reasonable idea of the size and shape of our Galaxy and the position of the solar system in it has often been likened to the Copernican revolution which ushered in the scientific renaissance in the 1600s.

In the 1920s when the nature of the spiral nebulae was still hotly debated upon, Edwin Hubble using the newly commissioned 100" telescope at Mt. Wilson was able to resolve Cepheids in the Andromeda nebula and provided the first measurement of a distance beyond our Galaxy. The existence of external galaxies was proved beyond doubt. Armed with the powerful tool of Cepheid variables as standard candles, Hubble and then others extended distance measurements to the Local Group galaxies and beyond. Using Cepheids in the nearby regions and then devising secondary indicators (e.g. brightest stars, supernovae, globular clusters, etc.) which were calibrated with respect to the Cepheids and RR Lyr variables to go further, and finally by using these secondary indicators to calibrate galaxy diameters and galaxy magnitudes in clusters, astronomers, during the decades following Hubble's work were thus able to reach out to cosmological distances. The series of efforts resulted in the refinement and extension of the calibrated velocity distance relation that was first given by Hubble in 1929.

Cepheid variables are thus seen to have played a seminal role in setting up the extragalactic distance scale by being the first step of the cosmological distance ladder.

Cepheids are a class of regular pulsating variable stars with periods ranging from a couple of days to well over a hundred days. They are of spectral types F to G and are intrinsically bright, belonging to the luminosity classes of bright giants and supergiants. Their internal structure and evolutionary status as core-He burning stars are well understood and highly sophisticated models are available that reproduce all of their observed properties. On the HR diagram they occur in a narrow strip somewhat inclined to the temperature/colour axis and it was observationally shown that their period depends both on the luminosity and the colour. The P-L-C relation, which is of fundamental importance in measuring extragalactic distances, has also been derived theoretically from the models and it is in excellent agreement with the P-L-C relation determined empirically. The best calibration of the relation comes from Cepheids in open clusters whose distances are known to great accuracy through the fitting of their main sequences to the Hyades main sequence, the latter being calibrated directly in absolute magnitudes through the method of moving cluster parallaxes. Thus the study of Cepheids is very

secure both theoretically and observationally and hardly any substantial change will occur in any of the results based on the properties of these stars.

Distances to the Local Group galaxies and to other galaxies slightly beyond have been estimated using Cepheid variables as standard candles. A variety of other calibrators have also been used to estimate the distances to these galaxies. The best measurements to date are available for the Magellanic Clouds. In their case the distance moduli obtained by different methods agree to within $0''.10$. Until the HST and the CFHT measurements the farthest the Cepheids were seen were in M101 at a true distance modulus $(m - M)_0 \sim 29''.5$. Even at this distance the other methods led to distance estimates in good agreement with the ones obtained through Cepheids. However, the distance is yet too small to see an unambiguous Hubble flow. Determination of cosmologically significant distances for deriving H_0 had depended totally on the use of secondary distance calibrators.

Distance estimates to the Virgo cluster

The Virgo cluster forms the core of the Local Super-cluster. Its role in the determination of the extragalactic distance scale has been crucial. The cluster is large and it contains the full complement of galaxies of different morphological types allowing for the application of almost all the methods of distance estimates at hand including those using novae and supernovae of different types since the richness of the cluster ensures that even these rather rare events are not too infrequent in it. Further the cluster is at a high galactic latitude such that the foreground extinction to it is not a problem. It is ideally located for observations from both hemispheres of the globe. And lastly it is sufficiently distant so that most of its recessional velocity derives from the Hubble expansion.

Before 1994 the distance estimates to this cluster were all based on secondary and tertiary calibrators since technology did not allow yet the discovery of Cepheids in its member spirals. Table 1 lists these estimates from a variety of sources. Dichotomy of the results is quite evident. While surface brightness fluctuations, the planetary nebula luminosity function and the Tully-Fisher relation lead to a short distance to the cluster

Table 1. Distance of the Virgo cluster

Method	Author and ref.	$(m - M)_0$
Planetary nebulae	Jacoby <i>et al.</i> ¹²	30.74 ± 0.05
Surface brightness fluctuations	Tonry <i>et al.</i> ¹³	30.86 ± 0.13
Tully-Fisher	Pierce and Tully ¹⁴	30.88 ± 0.22
Globular clusters	Harris <i>et al.</i> ¹⁵	31.47 ± 0.25
Novae	Capaccioli <i>et al.</i> ¹⁶	31.30 ± 0.36
SN 1979C in M 100	Schmidt <i>et al.</i> ¹⁷	31.40 ± 0.60

$(m-M)_0 \sim 30.7$, SN Ia, the globular cluster luminosity function and novae lead to a long distance with $(m-M)_0 \sim 31.4$. The long distance is also supported by measurements that use diameters or scale lengths of Sc I galaxies as calibrators. The difference in the distance moduli between the two sets, which is nearly a full magnitude, translates to a distance ratio of about 1.4. This large difference has been principally responsible for the controversy surrounding the value of the Hubble parameter H_0 , since the dispersion in the velocity estimates of the member galaxies of the Virgo cluster produces a much smaller uncertainty. It has also been noted in the literature^{4,5} that though the absolute distance to the Virgo cluster was in dispute, the relative distances of distant clusters with respect to Virgo were not. A variety of methods yielded very similar relative distances to the Coma cluster with uncertainties in $D(\text{Coma})/D(\text{Virgo})$ which are less than 10%, more typically on the order of 5%. It was thus realized that an accurate distance estimate to the Virgo cluster using a primary calibrator could lead to an equally accurate absolute distance to the Coma cluster where the Hubble recessional velocity is easily an order of magnitude larger than the typical random motions of galaxies within the cluster. This would then lead to an accurate determination of H_0 . One of the key projects assigned to the Hubble Space Telescope was thus the discovery and measurement of classical Cepheid variables in the spirals of the Virgo cluster. It is my personal belief that the eventual naming of the Space Telescope was consciously or unconsciously influenced by this very important task that it was to undertake.

HST and CFHT observations of Cepheid variables in Virgo cluster

In 1994 two independent groups^{4,6} announced the first discovery of classical Cepheid variables in the spiral galaxies NGC 4571 and NGC 4321 (M 100) which are members of the Virgo cluster. While twenty odd Cepheids were resolved by the Hubble Space Telescope in M 100, ground-based efforts using a sophisticated high resolution camera (HR Cam) on the Canada-France-Hawaii Telescope atop Mauna Kea, could discover three Cepheids in NGC 4571.

Cepheids in M 100

M 100 is a giant Sc galaxy with a projected location $3^\circ.9$ away from the centre of the cluster defined by the giant elliptical galaxy M 87 (Virgo A, NGC 4486). The HST measurements have covered full cycles of about twenty Cepheids in this galaxy with periods ranging from 20 to 65 days. Both V band and I band measurements were made. The mean V and I magnitudes

and the measured periods define a nearly perfect linear relation that was indistinguishable in its slope from the absolute P-L relation of the LMC Cepheid sample. The reddening-corrected true distance modulus led to $D(\text{M 100}) = 17.1 \pm 1.8$ Mpc based on an LMC $(m-M)_0 = 18.5$. This direct estimate is close to the value obtained by the use of the Tully-Fisher relationship ($D = 18.4 \pm 2.2$ Mpc), but very different from Sandage's values of $D = 27.7$ Mpc based on a calibration of the diameters of Sc I galaxies.

Cepheids in NGC 4571

The ground-based sample of Pierce *et al.*⁴ contained certain identification of two classical Cepheids and one suspected one in NGC 4571. This galaxy is located at less than $2^\circ.5$ from M 87 as projected in the sky. Further it shows evidence of significant HI stripping. Its kinematics shows that it is close to the cluster core and most likely is in orbit around the dynamical centre of it. The periods of Cepheid variables range from 50 to 90 days and again define a linear relation with their mean R magnitudes, the slope of which is the same as found in the LMC Cepheid sample. The distance $D(\text{N4571}) = 14.9 \pm 1.2$ Mpc.

Observations of classical Cepheids in two of the spirals of the Virgo cluster seem thus to support the so-called short distance scale to this cluster ($D_{\text{Virgo}} \sim 15 \pm 2$ Mpc). But before deriving H_0 based on these distances the measurement of velocities of the cluster galaxies should be critically examined to infer the true Hubble velocity of the cluster.

Cosmic velocity of the Virgo cluster

Our local region of space, cosmologically speaking, shows a complexity of motion that needs to be disentangled before the true Hubble flow of the Virgo cluster can be estimated. It has been known for several years now that our own Local Group has a Virgocentric flow of a few hundred km s^{-1} . Observations of the 3 K Cosmic Microwave Background (CMB) show a dipole anisotropy, implying a motion towards its warm pole, but the direction does not coincide with the direction of the Virgo cluster in the sky. Some years ago it was postulated that there is a Great Attractor (GA), a large hidden clump of mass towards which all galaxies in the local superbubble (defined as a cell within $V_r \leq 6000 \text{ km s}^{-1}$) are attracted. More recent and extensive data by Mathewson *et al.*⁷ have demolished the GA concept and it is now well established that the nearly bulk peculiar motion of the local superbubble gradually peters out beyond 6000 km s^{-1} , merging gradually into the unperturbed Hubble flow.

In the currently accepted picture of the dynamics of

the local region consistent with all kinematic data, there are two components to the motion of the Local Group relative to the frame of CMB: (i) the perturbation of the free expansion of it from the Virgo region due to the mass of the Virgo cluster complex and (ii) the large scale nearly bulk motion of the local bubble of size $V_r \leq 6000 \text{ km s}^{-1}$ relative to the CMB, carrying the Local Group and the Virgo complex with it. Figure 1 displays a vector diagram of the velocities in the local region, adapted from Sandage and Tammann⁸. These authors assert that the peculiar dipole motion toward the CMB within the Local Supercluster and beyond is so small that it can be neglected in the determination of H_0 .

The most direct method of determining the true Hubble velocity of the Virgo cluster is to use the Hubble diagram with redshifts of remote clusters in the kinematic frame of the CMB plotted against the relative distance of these clusters with respect to the Virgo cluster expressed as a difference in their distance moduli. This is a line with a slope of 5. An extrapolation to zero in abscissa then gives the cosmic redshift at the distance of the core of Virgo cluster, devoid of all streaming motions. In this way Sandage and Tammann⁸ (*op. cit*) estimate the true Hubble velocity of the Virgo cluster to be $1179 \pm 17 \text{ km s}^{-1}$.

Hubble parameter H_0

There are two independent ways of obtaining H_0 from the recent measurements of the distance modulus to the two spirals. It is assumed, of course, that both the spirals belong to the Virgo cluster and are not foreground or background objects.

(1) Using the result, $V_{\text{Virgo}} = 1179 \text{ km s}^{-1}$, we find $H_0 = \frac{1179}{17} = 69 \text{ km s}^{-1} \text{ Mpc}^{-1}$ based on the distance to M 100 and $H_0 = \frac{1179}{14.9} = 79 \text{ km s}^{-1} \text{ Mpc}^{-1}$ from the distance to NGC 4571.

(2) Using the argument from the section 'Distance

Figure 1. Schematic diagram of the combination of the 'infall' of the Local Group toward Virgo of 220 km s^{-1} and the 'infall' of the 'local cell' of size $\sim 6000 \text{ km s}^{-1}$ (including the Virgo complex and the Local Group) toward Hydra-Centaurus at 460 km s^{-1} , giving an apparent motion of the Local Group of 600 km s^{-1} toward the warm pole of the CMB.

estimates to the Virgo cluster', described above, that the relative distance $D(\text{Coma})/(\text{Virgo})$ is very secure and that its value is 5.5, we obtain $D(\text{Coma}) = 94 \text{ Mpc}$ and 82 Mpc respectively from the two distance measurements and then using $V_{\text{Coma}} = 7,100 \text{ km s}^{-1}$ to reach $H_0 = 75 \text{ km s}^{-1} \text{ Mpc}^{-1}$ and $87 \text{ km s}^{-1} \text{ Mpc}^{-1}$.

Since there is still disagreement on the true cosmic velocity at the distance of the Virgo cluster, while as stated before the various methods of obtaining distances yield reliable results for the relative distance of the Coma cluster to the Virgo cluster, the second option of determining H_0 would seem to be more prudent. Thus direct measurement of the distance to the Virgo cluster appears to indicate that the true value of the Hubble parameter is close to $80 \text{ km s}^{-1} \text{ Mpc}^{-1}$, implying that the Universe is no more than 12.5 Gyr old if its expansion has been uniform in the past.

Disagreement with estimates based on SN Ia

Although great confidence is placed on the estimate of distances using classical Cepheids as the standard candles, secondary calibrators still occupy a very important place in setting up the extragalactic distance scale. Beyond the Virgo cluster it is the use of these secondary calibrators which lead to any distance measurement at all. Among the secondary calibrators, SN Ia occupies a unique position. These supernova are extremely luminous as point sources and they occur in all kinds of galaxies. Their observed light curves in all these galaxies appear to be remarkably uniform. The shape of the light curve is theoretically well understood. According to the currently accepted view, these supernovae are thermonuclear explosions of white dwarfs which accrete matter from a binary companion and ignite carbon in their degenerate cores which then disrupts the star completely. The characteristic light curve shape is theoretically reproduced by trapping and thermalization of the decay products of radioactive ^{56}Ni and ^{56}Co in $1.4 M_{\odot}$ of ejected matter. This model brings with it a self-calibration of the peak luminosity. An impressive amount of theoretical work has been done over the years on SN Ia explosions and these lead to a computed peak luminosity in the neighbourhood of $M_B = -19.5$. Empirical calibrations of SN Ia luminosities have depended upon observations of these supernovae in various galaxies whose distances are estimated by other methods. Those supernovae for which prepeak B and V light curves are available had their peak luminosities calibrated with reasonably good accuracies.

Since two well-known SNe Ia occurred in galaxies near enough for the HST to look at their Cepheid population, an equally important project for HST was to use the Cepheids in these galaxies to calibrate the peak luminosity of SN Ia. Saha *et al.*^{9,10} observed a number of Cepheids in NGC 5253 and IC 4182 the

host galaxies of the well observed SN 1972E and 1937C respectively. Using the Cepheid distances to these galaxies the peak luminosities of the SNe Ia were calibrated in B and V. The final values of $M_B(\text{max}) = -19.65 \pm 0.13$ and $M_V(\text{max}) = -19.60 \pm 0.10$ are in good agreement with the theoretical self-calibrated values.

To obtain the Hubble parameter from SN Ia measurements it is customary to use the SN Ia Hubble diagram which is a plot of the velocities of receding galaxies versus SN Ia V magnitudes in them. From Sandage and Tammann⁸ one obtains: $\log V_r = 0.2V + 0.658$, and hence $\log H_0 = 0.2M_V(\text{max}) + 5.658$. The value of H_0 obtained from these measurements is $52 \pm 9 \text{ km s}^{-1} \text{ Mpc}^{-1}$. This value disagrees with the high value obtained directly from the Cepheid variables. Thus there is discrepancy between the Cepheid measurements and SN Ia measurements and it is sure to focus attention on the estimates of SN Ia magnitudes used in producing the SN Ia Hubble diagram and also on the suitability of SN Ia as standard candles.

Implications of the new measurement

The HST is carrying out further measurements of classical Cepheid variables in other member spiral galaxies of the Virgo cluster and though it may take some more time to pin down the distance to the Virgo cluster with much higher accuracy, it may not be totally out of place now to discuss the implications of a high value of H_0 , should it come to stay.

The Hubble parameter in a simple sense determines how big the Universe is and how old it is. The inverse of it, which has the dimensions of time, characterizes the time scale for the expansion of the Universe at any epoch. Thus if the Universe expanded uniformly, $1/H_0$ would be the age of the Universe in Gyr (1 Gyr = 10^9 yr). However, since the Universe contains matter, it is natural to assume it has decelerated since the expansion began and in the most popular cosmological model, known as the Einstein-de Sitter model (also the Standard Model) with $\Omega_0 = 1$ and $\Lambda = 0$, the age is $2/3 H_0$. The question of the age is thus intimately related to three parameters H_0 , Ω_0 and Λ . Ω_0 is a dimensionless measure of the density of matter in the Universe and determines the deceleration of its expansion. Formally, $\Omega_0 = 8\pi G\rho/3H_0^2$, where ρ is the density of matter and G the universal gravitation constant. Λ is known as the cosmological constant, first introduced by Einstein in 1917 to obtain static solutions to the field equations of general relativity as applied to the Universe. It represents the energy density of the vacuum. So far it has not been possible to obtain either Ω_0 or Λ from observations. While all cosmological models (Friedmann Universes) set $\Lambda = 0$, a variety of arguments and deep philosophical convictions have led to the belief that we live in a Universe where $\Omega_0 = 1$ (see ref. 11 for a detailed dis-

cussion of these premises). Since visible matter perhaps makes up for only 1–5% of the total density required for Ω_0 to be unity, it has been commonly assumed that most of the matter in the Universe is dark or invisible. Investigation into the nature and distribution of this dark matter is one of the most active fields of research today. The measurement of H_0 described earlier therefore leads to $T \approx 8$ Gyr.

There have been independent estimates of the age of the Universe. These are based on the estimates of the ages of the constituents of the Universe. Amongst the oldest objects in the Galaxy are the globular clusters. Their ages have been determined by a combination of theory and observation related to the evolution of stars. The current best estimates indicate that many of these globular clusters are at least 16 ± 2 Gyr old. This result is in conflict with the age of the Universe quoted above. Probably some uncertainties lurk in the background of the otherwise highly successful theory of stellar evolution requiring these ages to be revised downward but the general consensus is that it will never be to the extent of a factor of two that is required by the new estimates of H_0 . If the assumption of $\Omega_0 = 1$ were relaxed and only the value of it consistent with early nucleosynthesis (abundances of D, ^3He , ^4He) and the virial masses of clusters of galaxies were adopted, which is a number between 0.1 and 0.2, even then the age of the Universe could hardly be increased beyond 11 Gyr for an $H_0 \sim 80 \text{ km s}^{-1} \text{ Mpc}^{-1}$. The only choice that remains, therefore, is to abandon the assumption of $\Lambda = 0$. If a positive cosmological constant were allowed, the age of the Universe can be lengthened sufficiently to accommodate the ages of globular clusters and of oldest stars.

Thus the implication of the new measurement of H_0 seems to be rather profound and would indicate that our preferred cosmological model needs fundamental revision. Further it may open up new directions of research and spur the observational quest for the value of Λ .

*Present address: Molecular Biophysics Unit, Indian Institute of Science, Bangalore 560 012, India

High resolution two dimensional NMR spectroscopy has become one of the important tools in the elucidation of three dimensional solution structure of fair-sized biomolecules. In this article we summarize the application of 2D NMR techniques to unravel the structure of small proteins and peptides. The basic theme is the systematic identification of the small number of secondary structural motifs such as α -helices, β -sheets and β -turns present in polypeptides using their through bond and through space fingerprints in the 2D NMR correlation maps. The method is illustrated using a 32-residue peptide which corresponds to a calcium-binding domain in the protein calmodulin.

AMONG the various spectroscopic methods that are employed in the elucidation of the three-dimensional structure of large biomolecules such as infrared¹ (IR), Raman², fluorescence³, circular dichroism (CD)⁴ and nuclear magnetic resonance spectroscopy⁵⁻⁹, only NMR has become one of the most sought after techniques because of its several unique capabilities. The NMR technique which started off as a physicists' tool for measuring magnetic moments of nuclei in the fifties, today finds immense use in the biological sciences and diagnostic medicine¹⁰⁻¹³. Because of its power to reveal information on the three-dimensional conformation of large molecules in solution, NMR has become a complementary technique to X-ray crystallography. For X-ray crystallography, however, one needs single crystals of optimal size. In contrast, NMR can give information on the macromolecules even when these *tumble freely* in solution, and this has made it an important technique for the understanding of structure activity correlation in biomolecules. This is very useful since many bioactive proteins and sugars are rather difficult to crystallize. Good structural correspondence between X-ray and NMR results has been obtained in a number of globular proteins¹⁴⁻¹⁶, although instances are known where significant differences have been noted^{17,18}. Another advantage of the NMR technique is that biomolecules can be studied at a simulated environment characterized by a specific pH, temperature, presence of ionic substances, etc. so that one is actually addressing the sample in physiological environment. Coupled with theoretical modelling¹⁹⁻²³ the NMR technique has provided us with a wealth of information on

protein folding^{24,25}, denaturation^{26,27}, intermolecular interactions^{28,29}, etc. It is now well established that the activity of a biomolecule critically depends on its three-dimensional conformation^{30,31}. It is known that the secondary and tertiary structures are dependent on the solvent medium, temperature, pH, presence of ions, etc. One of the major areas of research endeavour in molecular biology is 'protein folding', which is a fascinating and intriguing subject. Since the biological activity of proteins and polypeptides depends critically on the topography of the molecule apart from polarity and hydrogen bonding complementarity, it is important to get a first hand knowledge of the stereochemistry of the active site before one can start understanding biological (enzymatic) catalytic processes. This is because a transmembrane protein for example, may adopt different conformation as it traverses through the lipid membrane from the extracellular or intracellular region. It is also known that many of the enzyme proteins, which get activated only in the presence of certain metals, have different structures in the metal-bound and metal-free state. A myriad of one and two-dimensional (even higher dimensional) pulsed NMR techniques have been developed in the recent past³²⁻³⁴. The multi-dimensional techniques³⁵⁻³⁷ in particular, have helped in the increase in resolution needed for studying large biomolecules, by spreading the frequency in more than one dimension. In this process these methods also establish unique through-bond and through-space connectivities. With the current limit of supercon magnet reaching 750 MHz for ¹H, biomolecules up to a molecular weight of 20 kD can be studied.

Compared to X-ray in which the position of heavy atoms is determined around 2 Å resolution, in NMR distances between 2 Å and 5 Å unit can be resolved. The quantification is rather difficult due to possible motional effects leading only to an *average* distance information. In spite of this incomplete determination of internuclear distances, three-dimensional structures obtained from NMR agree well with the corresponding crystal structures, although significant differences between solution and crystal structures have been observed in many instances. The reason for the success of the NMR method is that the three-dimensional structures of proteins are governed by the general principles

of organization in which a few limited secondary structural motifs play an important role. NMR is uniquely adopted to detect the presence of these secondary structures through NOE (*vide infra*). In fact, the detection of a very long range interaction (through space connectivity between residues far apart in the sequence) reveals specific folding of the chain to organize the secondary structures. Normally the distances are estimated by comparing the NOE cross peak intensities from a 2D NOESY spectrum⁸. The $\langle r^{-6} \rangle$ dependence of the cross peak intensity will greatly reduce the relative error in the estimation of the distances which is six times lower compared to that of intensities³⁷.

In this article we describe the use of 2D NMR techniques in the elucidation of the three-dimensional structures of polypeptides. A brief description of the methods involved in the structural elucidation of peptides is illustrated by high resolution NMR studies on a synthetic 32-residue peptide corresponding to the first calcium-binding site of the protein calmodulin.

The severe overlap of resonances places an upper limit of ≈ 10 kD on the molecular weight of peptides that can be studied by 2D NMR. As the molecular weight increases, further spectral simplification would require adopting 3D techniques, which improve the resolution. Often site selective isotopic substitution can enormously simplify the interpretation of spectra^{38,39}. If the protein aggregates in solution, difficulties arise due to the broadening of the lines. A minimum of 1–2 mM of the protein itself is required to get the optimal S/N ratio in the spectrum. Most of the strategies developed for structural elucidation of proteins are also applicable to polypeptides.

2D NMR spectroscopy

In high resolution NMR, two major parameters, the chemical shifts and the scalar coupling constants, are needed to characterize a molecule. These give information as to the nature of the functional groups and the coupling patterns in the molecule. In addition, the nuclear Overhauser effect provides information regarding the spatial proximity of non-bonded nuclei. A complete information on the spin pattern and the through space connectivities of a molecule, should in principle, lead to the elucidation of the three-dimensional structure. However, as the molecular weight increases, the spectrum becomes complex due to severe overlap of spectral features. Therefore using 1D NMR spectroscopy, unequivocal evaluation of the spectral parameters is difficult. This becomes even more formidable when one addresses the problem of fair sized biomolecules. Methods have therefore been developed to increase the resolution of the spectrum, by spreading the same into a second dimension and in some cases even to a third dimension. The idea of a

2D strategy in NMR experiment was first suggested by Jeener⁴⁰. Later various groups contributed to the development of a number of 2D techniques^{32,41–49}.

The normal 1D NMR spectrum (whether CW or FT) is a 2D representation with one axis representing the chemical shift and the second axis, the intensity. A 2D spectrum consists of two axes representing frequencies and the third axis, intensity. 2D NMR spectra are generated using time domain techniques wherein the spin system is subjected to pulses and time intervals, and typically consists of four time sectors labelled *preparation* (P), *evolution* (E), *mixing* (M) and *acquisition* (A) (Figure 1). The preparation consists of applying an rf pulse to generate non-equilibrium magnetization. The system is allowed to evolve during the evolution period, t_1 , under suitably *tailored* Hamiltonians. The third period, mixing, which is not mandatory for all 2D experiments, may consist of suitable pulses for effecting magnetization transfer, cross relaxation, chemical exchange, etc. The acquisition period, t_2 , during which the signals are observed, is free of pulses except in some heteronuclear situations where it may consist of decoupling of one of the spins. The total time duration from preparation to the start of acquisition should be much less than the spin-spin relaxation time of the system so that it *remembers* the previous history and retains all the phase memories.

Generally, in 2D experiments a set of 1D data are collected by systematically varying the time interval, t_1 , during the evolution period. The data thus acquired at the detection period, $S(t_1, t_2)$, are first Fourier-transformed

Figure 1. Schematic representation of 2D NMR. The four time periods are preparation (P), evolution (E), mixing (M) and acquisition (A). The signal $S(t_1, t_2)$ is acquired as a function of two time variables t_1 and t_2 . FT with respect to t_2 gives the interferogram $S(t_1, f_2)$ which upon FT with respect to t_1 gives the 2D spectrum $S(f_1, f_2)$. This can be represented either in a stack plot (inset on the top) or a contour plot (bottom inset).

along the t_2 axis. The intensities of signals, $S(t_1, F_2)$, vary as a function of t_1 , due to modulations of phase/amplitude depending upon the operative Hamiltonian. These data are then transposed and Fourier-transformed along the t_1 direction, to give the normal 2D spectrum, $S(F_1, F_2)$. A 2D spectrum consists of three types of peaks. *Diagonal* peaks which occur at the 45° diagonal of the 2D map, correspond to the magnetization which does not undergo any transfer and was not affected by pulses, delays, etc. between the preparation and acquisition period. (A projection of the diagonal peak on either axis represents the normal spectrum.) *Off diagonal* peaks or cross peaks occurring at coordinates (ω_i, ω_j) with the corresponding symmetry related peak occurring at (ω_j, ω_i) represent connectivities either through bond or through space. Axial peaks occur at $\omega = 0$ along the ω_1 dimension. These correspond to creation of fresh transverse magnetization signals that arise from the Zeeman magnetizations that recovered *via* spin-lattice relaxation during the t_1 period and as such do not have any useful information and can be removed by suitable phase cycling. 2D spectra are either represented in a stacked mode or in a contour form. Normally contour representation is preferred, as this is more informative, where the peak intensity is proportional to the number of contours encircling the peak position (see Figure 1).

Unlike in 1D spectra, it is not normally possible to expect pure absorption mode line shapes in either or both coordinate axes of the two frequency domains. Usually, a typical 2D NMR peak has a *phase twisted* line shape, with characteristic long tails extending well beyond the position of the lines. This is because, the 2D line shape function is often a mixture of absorption and dispersion in both the dimensions. Conventionally, the practice was to plot the absolute value mode spectrum $(u^2 + v^2)^{1/2}$ to avoid distortions in contour display. The FIDs are often weighted by suitable apodization functions⁴² to get maximum resolution. However, absolute value mode spectrum always leads to poor resolution, hence most of the 2D sequences and the mode of acquisition have been modified in recent times so as to produce pure absorption mode line shapes in both frequency domains⁵⁰.

The three most important homonuclear 2D NMR experiments are chemical shift correlation spectroscopy (COSY), total correlation spectroscopy (TOCSY) and nuclear Overhauser effect spectroscopy (NOESY). These methods involve the use of multipulse sequences, which manipulate the spins depending upon the internal Hamiltonian as well as the dynamics related to relaxation. Since nuclear spin systems are finite dimensional, the quantum mechanics of spin dynamics can be evaluated exactly^{32,33}. In this connection it is possible to use, the Cartesian spin operators such as I_x, I_y, I_z and their products such as $I_x S_z, I_x S_x$, etc., as a representation of the density

operator⁵¹. It is possible to precisely describe the state of the spin state and the fate of the same during the pulse sequences and the nature of the acquired signal using the density operator formalism.

Correlation spectroscopy

In COSY⁴² the system is subjected to a two-pulse sequence (Figure 2). The first pulse creates transverse magnetization of all the spins. These evolve in the laboratory frame with their characteristic chemical shift (δ) and spin-spin coupling (J). Those magnetizations corresponding to J coupled spins produce signed antiphase magnetization⁷ during the evolution in t_1 . The second pulse acting on these antiphase magnetizations effects a magnetization transfer coherently among coupled partners with the transfer rate being proportional to $J/2$. A 2D Fourier transformation of the acquired signal, therefore, produces off-diagonal peaks at coordinates

Figure 2. Pulse sequences for (a) 2D COSY, (b) 2D DQF COSY, (c) 2D TOCSY and (d) 2D NOESY. In (c) P corresponds to a composite pulse sequence for locking the magnetization in the transverse plane. In (d) τ_m is the NOE mixing time. The phases of the various planes denoted by Greek alphabets are suitably cycled to get the desired magnetization transfer pathway.

(ω_i, ω_j), indicating that the two spins with chemical shifts ω_i and ω_j are connected through bond. COSY establishes connectivity between all directly coupled spins in the system. A detailed description of the mechanism of J connectivity and the phase cycling required to produce pure phase spectra are given in ref. 32.

In the normal COSY methodology described above, the diagonal peaks are of inphase dispersion lineshapes, they have long tails, often obscuring cross peaks close to the diagonal. Isolated equivalent spins such as methyl, isopropyl and *t*-butyl also produce exclusive diagonal peaks with long tails and often interfere with the identification of other cross peaks close to them. Since 2D COSY is essentially a means for establishing J connectivity it is possible to improve the spectrum by using double quantum filtered COSY⁵², DQF COSY. In this method, the second 90° pulse of COSY is replaced by a pair of 90° pulses with a very short delay in between (Figure 2). The first of these pulses generates double and higher quantum coherences only among J coupled partners, which are converted into observable single quantum coherences by the last pulse. A suitable phase cycling is used so that the magnetizations which proceed through a double quantum coherence pathway are exclusively accounted for in the t_2 period. Since solvents (water, CDCl₃, DMSO, acetone, benzene, etc.) and isolated spins [–OCH₃, –C(CH₃)₂, etc.] do not possess J coupling, signals from these are eliminated from the 2D spectrum. Further, when the experiment is carried out in pure phase mode, the diagonal peaks (which now represent only spins with J coupled partners) become quite narrow because of pure absorption line shapes and enable identification of cross peaks close to the diagonal. It is to be pointed out that in going from COSY to DQF COSY, though the resolution is enhanced, there is a decrease in sensitivity since the conversion from single quantum to double quantum and back to single quantum leads to loss of magnetization in both conversions by the creation of zero quantum and zz magnetizations⁵³.

Total correlation spectroscopy

To establish the sequential J connectivity in a molecule, an extension of COSY is used which relies on successive relay of magnetization between spins in a network. It can be shown using density operator method, just as a single 90° pulse following a preparation pulse can transfer magnetization between directly coupled partners, further evolution followed by a third pulse will transfer magnetization between spins having a common coupling partner. Such a strategy is called relayed COSY^{54,55}, and will establish the connectivity between spins having common coupling partners. A further extension of the relayed COSY which establishes complete connectivity

among spins in a consecutive network of coupled spins is known as total correlation spectroscopy (TOCSY)⁵⁶ or Homonuclear Hartmann Hahn spectroscopy⁵⁷ (Figure 2). In this method, after the creation of the transverse magnetization by a first pulse the spin system is effectively locked in the transverse plane using suitable continuous or composite pulse sequences^{58–61}. Under the circumstances, the chemical shift becomes effectively zero in the rotating frame and the spin system evolves under a strong coupling Hamiltonian, J.I.S. It can be shown that such a strong coupling Hamiltonian, depending upon the various coupling constants in the network, transfers magnetization coherently back and forth at a number of frequencies⁶², thereby establishing complete connectivity within the network.

Nuclear Overhauser effect spectroscopy^{63–67}

Through space connectivity in NMR is achieved by nuclear Overhauser effect spectroscopy. The intensity of a resonance signal in an NMR spectrum is proportional to the population difference between two energy levels of the corresponding transition and, in thermal equilibrium, is governed by Boltzmann statistics. When the equilibrium populations are disturbed (*via* rf absorption), the return to equilibrium is determined by the transition probabilities. Among the various levels in the system, the internal interactions such as chemical shift anisotropy, homo and heteronuclear dipolar coupling, nuclear electric quadrupole coupling and spin rotation interactions, are made to fluctuate due to the random Brownian motion and these bring about the transitions among the levels via radiationless processes. Among all the mechanisms that bring about the establishment of Boltzmann equilibrium, the dipole–dipole relaxation is the most important, and is almost exclusively the main cause for relaxation for protons. Under this mechanism, the transition probability depends on the strength of the local field component fluctuating at the frequency corresponding to the transition under consideration. This local field is the field at the site of a given magnetic nucleus due to the presence of other dipoles.

The sequence for 2D NOESY is given in Figure 2. The first two 90° pulses effectively invert all the magnetization to the $-z$ -axis. The non-equilibrium Zeeman magnetization tends to reach equilibrium via spin lattice relaxation brought about by dipole–dipole interaction (NOE) as explained before. In this process magnetizations get transferred between spins at a rate proportional to r^{-6} . A third pulse applied after a delay, known as the mixing time, τ_m , generates a 2D spectrum, where the cross peaks establish dipolar connectives; suitable phase cycling is used to get pure phase spectra. Because the efficiency of 2D NOESY depends critically on $\omega\tau_c$, the viscosity of the medium and hence the temperature of

measurement are the factors to be controlled, along with the optimization of τ_m . It is the capability of the NOE effect to establish magnetization transfer among dipolar partners in solution that makes the 2D NOESY the only method that can provide distance information in solution.

3D structure of peptides⁶⁸

Amino acids are the basic building blocks of peptides. All the amino acids, with the exception of proline, have a carboxyl and an amino group on the α -C atom. The individual amino acids differ in the side chain, being either aliphatic, aromatic or heterocyclic. They are usually represented by the first three letters of their names (e.g. alanine, Ala) or in short by a one-letter code (e.g. lysine, K; phenylalanine, F; etc.). The amino acids are linked together by a peptide bond to form the polypeptide chain. The peptide bond exhibits a partial double bond character and hence the six atoms, C_α -CONH- C'_α , that characterize the peptide moiety lie in the same plane. Thus the chain can only turn at the C_α atoms around the bonds N- C_α and C_α -C' corresponding to the dihedral angles ϕ and ψ . These two dihedral angles characterize the peptide backbone structure shown in Figure 3. Pro-

Figure 3. Dimensions of the peptide bond. The six atoms C_α -CO NH- C_α lie in a plane. The chain has the ability to turn only at the C_α atoms around the angles ϕ and ψ . Here R corresponds to the continuity of the backbone while R' represents the sidechain in any residue. (Adapted from ref. 31.)

teins are generally described by their primary, secondary and tertiary structures. The primary structure basically identifies the various amino acid residues in their exact sequence usually numbered from the N-terminal end. The secondary structure brings about additional stabilization of the molecule through intra- and inter-molecular hydrogen bonds leading to, surprisingly, a limited number of structural motifs such as α -helix, β -sheet and β -turn. Tertiary structure is brought about by the interaction among the various secondary structural elements through electrostatic, hydrophobic, van der Waals type interactions, etc. The number of protein structures solved by NMR is increasing at a tremendous pace. The advent of supercon magnets and highly sophisticated softwares to build protein models from the NMR distance data have made this one of the most important techniques^{69,70}.

Identification of secondary structures by NMR

Figure 4 shows the major secondary structural elements that are found in proteins and polypeptides. Each of these structural elements has characteristic through space connectivities, identification of which is the first step in understanding the phenomenon of protein folding^{71,72}. The characteristic folding of the polypeptide chain brings different residues in close proximity and confers the overall structure on the molecule. The quantification of internuclear distances through NOE can help in arriving at the secondary structure.

The various interproton distances that are present in a folded peptide, are generally classified as sequential, medium range and long range, depending upon the number of intervening amino acid residues. By convention, the distance between protons A and B, located in amino acid residues at position i and j is denoted by $d_{AB}(i, j)$. For example, the distance between the α proton of the i th residue and NH proton of the j th residue is denoted as $d_{\alpha N}(i, j)$. Sequential distances between the backbone protons are labelled as $d_{\alpha\alpha}(i, i+1)$ and $d_{NN}(i, i+1)$ and those between a backbone proton and β/γ protons in the side chain that are on nearest neighbour residues are labelled as $d_{\alpha/N\beta}(i, i+1)$. Medium range distances are the nonsequential inter-residue separation between backbone protons or between a backbone proton and a side chain proton, within a segment of five consecutive residues. Long range distances are those between backbone protons that are at least five residues apart⁵.

Apart from the sequential distances which characterize specific secondary and tertiary structures, the secondary structures are governed by a number of medium and long range proton-proton distances. In α -helix, the amino acid residues at position i and $i+3$ are in close proximity. The distance between NH proton of the i th residue and that of $(i+1)$ residue is short, being ≈ 2.8 Å. Also, the

distances $d_{\alpha N}(i, i+3)$, $d_{\beta N}(i, i+1)$, $d_{\alpha\beta}(i, i+3)$, are short. The presence of NOE between the above proton pairs, especially $d_{\alpha\beta}(i, i+3)$ and $d_{\alpha N}(i, i+3)$ characterizes the α -helix. β -sheets are formed when individual strands of the extended polypeptide chain come in close contact, stabilized by inter residue hydrogen bonds. These are characterized by short sequential $d_{\alpha N}$ and interstrand $d_{\alpha N}(i, j)$, $d_{NN}(i, j)$ and $d_{\alpha\alpha}(i, j)$. The presence of inter-strand $d_{\alpha\alpha}(i, j)$ (long range NOEs) is unique for antiparallel β -sheets, whereas in parallel β -sheets $d_{\alpha\alpha}(i, j)$ contacts are in the range of 4.8 Å and hence have reduced NOE. Turns are short secondary structural elements comprising four residues. These are characterized by short sequential and medium range NOEs. Table 1 summarizes the various short proton-proton distances in the secondary structural elements of polypeptides.

Figure 4. Schematic representation of the secondary structural elements in peptides: (a) α -helix, (b) antiparallel β -sheet, (c) parallel β -sheet, (d) β -turn type-I, (e) β -turn type-II. Short proton-proton through space connectivities are indicated by arrows and the wavy lines correspond to hydrogen bonds. (Adapted from ref. 67.)

Besides NOE, regular secondary structures are also characterized by the three bond ($\text{H}-\text{N}-\text{C}_\alpha-\text{H}$) spin-spin coupling constant ($^3J_{\text{NH}-\alpha\text{CH}}$). The torsional or rotational angle around the $\text{C}_{\alpha\text{N}}$ bond (ϕ) is related to the proton-proton coupling constant that has been extensively used to probe the polypeptide conformation in solution^{73,74}. The procedure is based on the empirical relationship between the vicinal coupling constant and the dihedral angle ϕ . This is given by a Karplus type relation⁷³

$$^3J_{\text{NH}-\alpha\text{CH}} = A \cos^2 \phi + B \cos \phi + C, \quad (1)$$

where $A = 6.4$, $B = -1.4$ and $C = 1.9$ Hz. These have been derived using BPTI as a standard and by fitting the three bond $J_{\text{CH}-\text{NH}}$ measured in solution and the corresponding dihedral angles derived from X-ray structure. The coupling constant is generally used for complementing the NOE distance data for the elucidation of backbone conformation of the polypeptide. The spin-spin coupling constant is normally derived from a high resolution COSY or DQF COSY spectra. It is difficult to derive an accurate estimate of this. The lines in both the above mentioned 2D techniques, appear as antiphase absorption peaks and when the line width becomes of the order of the coupling constant, the experimental J is an overestimate of the actual J (ref. 75).

The measured NOE as well as J cannot be interpreted uniquely unless it is known that the structure corresponds to a single conformer. When the polypeptide exists as an equilibrium of rapidly interconverting conformers, the NOE and J are the weighted average of the distances r_i^{-6} and dihedral angles ϕ_i respectively. Since the averaging processes are nonlinearly dependent on geometry, it is often difficult to correlate the NOE and J in terms of a single conformation. When more than one conformation is possible for the molecule, the NOE derived distance⁸ may lead to a structure, which may be energetically unfavourable⁹.

Assignment of the spin systems

The information about the secondary structural content can be arrived at only when the resonances have been assigned to individual amino acids. For a small peptide, spectral overlap is minimum and useful information can be obtained from 1D NMR data itself. As the number of amino acid residues increases, the complexity of the 1D spectrum increases. This is because the NH resonances occur in the region 7–10 ppm. The appearance of all the NH residues, in a fair sized peptide, in this narrow region complicates the structural information that can be obtained from various 1D techniques. This problem is circumvented by the use of 2D NMR techniques wherein the information is spread along the second

Table 1. List of short proton-proton distances (Å) found in polypeptides and proteins characteristic of the typical secondary structural elements

Distance	α -Helix	3_{10} -Helix	β	β_p	Turn I	Turn II
$d_{\alpha N}$	3.5	3.4	2.2	2.2	3.4 3.2	2.2 3.2
$d_{\alpha N(i, i+2)}$	4.4	3.8			3.6	3.3
$d_{\alpha N(i, i+3)}$	3.4	3.3			3.1-4.2	3.8-4.7
$d_{\alpha N(i, i+4)}$	4.2					
d_{NN}	2.8	2.6	4.3	4.2	2.6 2.4	4.5 2.4
$d_{NN(i, i+2)}$	4.2	4.1			3.8	4.3
$d_{\beta N}$	2.5-4.1	2.9-4.4	3.2-4.5	3.7-4.7	2.9-4.4 3.6-4.6	3.6-4.6 3.6-4.6
$d_{\alpha\beta(i, i+3)}$	2.5-4.4	3.1-5.1				
$d_{\alpha\alpha}$	2.5-4.4	3.1-5.1				

dimension. An improved spectral resolution and good signal to noise ratio is achieved by the use of high field NMR spectrometers.

Two different approaches are available for the complete assignment of the polypeptide chain. One method, sequential resonance assignment developed by Wuthrich⁵, is based on the primary structure of the polypeptide. In this method, the side chains of the various amino acid residues are assigned first and then the secondary structural elements are identified. Yet another method^{76,77}, main chain directed strategy, is based on the secondary structure of the polypeptide moiety. In this, NOE patterns characteristic of the secondary structural elements are detected without regard to the side chain type.

Through-bond correlation

To start with, the amino acid residues present in the system should be identified. All amino acid residues differ only in their side chains with their characteristic coupling network. Identification of the side chain spin system helps to know the type of amino acid residues present in the system.

Several 2D NMR experiments give through bond connectivities via J and these are COSY, DQF COSY⁷⁸, relayed COSY and TOCSY. COSY and DQF COSY give information between directly bonded spin systems with a resolved scalar coupling. Typically in a small protein or polypeptide there would be hundreds of cross peaks. A careful analysis of COSY can give information on groups of coupled protons all present in the same residue. In other words, a given amino acid will have a basic COSY pattern quite characteristic of the residue type. For the 20 common amino acids one gets ten different COSY connectivity patterns for the aliphatic region and four for the aromatic rings (Figure 5). It is

Figure 5. Patterns of connectivities through spin-spin coupling for the twenty naturally occurring amino acid residues. Filled circle cross peaks correspond to 2D COSY and additional connectivities by open circles occur in 2D TOCSY.

possible to identify the various residues by analysing the specific COSY connectivity patterns. For example, the residue Val has a COSY pattern consisting of αCH - βCH cross peaks and two βCH - γCH_3 cross peaks. An AMX spin system, on the other hand, will produce a characteristic pattern of three cross peaks. The cross peak region between the amide protons and αCH protons is the so-called finger print region, which shows a single correlation for each amino acid with the exception of glycine where the NH proton shows a correlation to two αCH protons. The only residue that can be immediately identified from this finger print region is glycine. For type-specific identification of other amino acids, connectivity information between the αCH and the side chain protons is necessary. Pro is the only residue that does not give any resonance in the finger print region. When any amino acid is repeated several times in the sequence, often the cross peak region may be fraught with severe overlap, especially when these are part of the random coil region of the peptide.

The amino acid residues like Gly, Ala, Val, Thr, Leu and Ile have unique spin systems. These residues are directly assigned through COSY spectrum. The amino acids, Asp, Asn, Cys, Ser and the aliphatic protons of the His, Tyr, Trp and Phe belong to AMX spin system. In this spin system, αCH proton is attached to two βCH protons. Although in principle COSY should help in identifying various AMX patterns, severe overlap due to the presence of large number of AMX residues, impose limitation on the identification of the particular residue type. Thus, for a residue that has NH, αCH , βCH and γCH protons, the COSY connectivities will only be manifested between NH and αCH , αCH and βCH ; and between βCH and γCH protons. Other set of residues like Glu, Gln, Met have αCH attached to two βCH protons, which in turn are attached to two γ protons. It is difficult to assign the side chain resonances of the long side chain amino residues, like Lys, due to spectral overlap. This difficulty in most instances can be resolved by supplementing COSY data with relayed COSY or TOCSY data. A typical relay pathway is from NH- αCH to β proton with larger αCH - βCH coupling and from there to γ and δ protons. In principle, therefore, TOCSY permits the correlation of all protons within a given coupling network. TOCSY with optimized mixing time, enables the complete identification of all the different amino acids, by establishing connectivity from the NH proton down to the last side chain protons. The exception is for ring protons of Phe and His residues where there is no J coupling between β protons and ring protons. TOCSY experiments can resolve ambiguities arising from coincident chemical shifts of the side chain protons. TOCSY is also known to be more sensitive than COSY and can offer better resolution. TOCSY patterns are also included in Figure 5.

In situations where degeneracy or near degeneracy of two resonances occur, multiple quantum spectroscopy will be useful. For example, a stringent test for distinguishing AMX spin systems from those of long side chains is that the βCH - βCH cross peak of an AMX systems will be completely suppressed in four quantum filtered COSY³⁴. Similar multiple quantum strategies can be used to resolve ambiguities in addition to simplifying the complexity of the finger print region.

Through space correlation

After the identification of the resonances corresponding to the individual residues, it is necessary to identify every amino acid not only by its type but also by its position in the polypeptide sequence. NOESY gives information about distances between intra- and inter-residue protons within ~ 5 Å units. Depending upon the intensity of NOE peaks, classifying them as strong, medium and weak, one can roughly deal with three ranges of distances, namely short (< 2.5 Å), medium (2.5 – 3.5 Å) and long (3.5 – 5.0 Å). To distinguish the different ranges of through space connectivities the NOESY experiment is often carried out at a number of mixing times. Often NOE cross peaks corresponding to larger internuclear distances do not show up at short mixing times.

With the unique spin topology, obtained from a combination of COSY and TOCSY, sequential connectivities between two residues of known type may provide a starting point in the sequence. This point usually corresponds to a dipeptide unit unique in the sequence. To avoid branching in the wrong direction it would be helpful to locate several di or tri peptide connectivities located along the backbone of the protein. Careful analysis of the NOESY peaks in the finger print region, when looking for specific patterns of short distances corresponding to the various motifs (α -helix, β -sheet) can, in principle, help in the assignment.

At first sight the above procedure seems quite straightforward. However, the NH- αCH protons of α -helices show little chemical shift dispersion^{79,80}, compared to β -sheet structure and often only about 50% of the residues can be identified easily. For example, two overlapping NH resonances may show intra residue and sequential NH- αCH connectivity and it becomes difficult to distinguish which of the four cross peaks correspond to which of the amide protons.

Often changes in temperature, pH and amide proton exchange when dissolved in D_2O , can simplify some of the complications. In larger peptides and proteins, several NOE experiments have to be performed by varying the experimental conditions. As was mentioned previously the secondary structures do produce recognizable finger prints in the NOESY spectrum. α -helices for example,

are characterized by a sequence of short NH–NH connectivities [$d_{\text{NN}}(i, i+1)$, $d_{\text{NN}}(i+1, i+2)$, ...] corresponding to a repetitive distance of 2.8 Å. The NH– α CH distances in α -helix give strong NOE cross peaks. In addition, weak inter-residue correlation between NH– α CH of the preceding residue $d_{\alpha\text{N}}(i, i+1)$ and to the α CH of the residue three positions earlier $d_{\alpha\text{N}}(i, i+3)$ characterize the α -helix. Other connectivities in the α -helix are $d_{\alpha\beta}(i, i+3)$, $d_{\beta\text{N}}(i, i+1)$ and relatively weaker $d_{\alpha\text{N}}(i, i+2)$, $d_{\alpha\text{N}}(i, i+4)$.

Antiparallel β -sheets will have, in addition to their interstrand α CH– α CH cross peaks, intense $d_{\alpha\text{N}}$ connectivities. Parallel β -sheets on the other hand, show sequential $d_{\alpha\text{N}}$ connectivity but rather weak interstrand α CH cross peaks. Figure 6 summarizes the various through space, NOE connectivities expected for typical secondary structural elements found in peptides and proteins.

A complementary information regarding secondary structure is obtained by quantitatively analysing the NH– α CH spin–spin coupling. Often this is done from DQF COSY spectrum with a high digital resolution in the finger print region. The Karplus relation and experimental data show that in general, this $^3J_{\text{NH}-\alpha\text{CH}}$ is in

the range of 4–5 Hz for α -helix whereas it is nearly 9 Hz for β -sheets. The various turns (type I, II, etc.) cannot be distinguished from α -helix using this information alone.

When ambiguity arises in the total assignment of the spectrum using the 2D methods mentioned above, one can resort to additional techniques such as double labelling with ^{13}C and ^{15}N of specific residues in the sequence which will aid in the assignment. This is because ^{13}C exhibits long range $^2J_{\text{C-H}}$ with NH of the next residue and its own α CH. Each amide ^{15}N has a resolved coupling with its own hydrogen ($^1J_{\text{N-H}}$) and with the α CH of the preceding residue. In peptides which lie in the intermediate tumbling region ($\omega\tau_c = 1.12$), NOESY fails and one has to resort to ROESY^{81,82} as well as the above mentioned isotopic labelling methods to arrive at the 3D structure. Another useful method is to label the side chain randomly to about 75% with ^2H . This leads to a substantial gain in the resolution because of the lengthening of the T_2 (refs 83, 84). In addition, the improved resolution is also due to the removal of spin–spin coupling between α CH and aliphatic protons. Random deuteration of the side chain leads to a gain in sensitivity in the NH–NH region of the NOESY spectrum as well, because during the mixing period of the experiment, there is a substantial reduction in the loss of magnetization due to the deuterated aliphatic chains⁸⁵.

Once the assignments of coupling network and unambiguous interpretations of NOESY spectra have been accomplished, one can resort to using this information in a distance-constrained molecular modelling study⁸⁶. However, a detailed description of the procedures will not be dealt with in this article. A schematic diagram for arriving at the most probable structures using the NMR-derived parameters as constraints is given in Figure 7.

In Figure 8 the overall summary of the structure determination of the biomolecules using NMR and NMR-assisted modelling studies is provided as a flow chart.

3D structure of a 32-residue peptide

In this last section we have taken an illustrative example from our attempts to study the 3D structure of some synthetic CaM fragments⁸⁷ corresponding to the various calcium-binding sites in isolation to see whether these have reasonable extent of secondary structures. The peptide chosen is labelled 1–1–1 and corresponds to the first calcium-binding site characterized by helix 1–loop 1–helix 1 corresponding to the residues 10–41 in the native CaM molecule, namely, AEFKEAFSLFDK DGDGTITTKELGTVMRSLGQ.

Experimental

The CaM fragments were synthesized using a modified

Figure 6 a, b. a, Schematic representation showing through space connectivities in peptides between protons which give NOE cross peaks. b, The various through bond connectivities in typical secondary structural elements in peptides that give NOE cross peaks. Merrifield solid phase method⁸⁸. The crude peptide was purified by reverse-phase HPLC and the purity and identity was confirmed by analytical HPLC and by amino acid sequencing. NMR experiments were carried out using a JEOL GSX 400 spectrometer and a BRUKER AMX 600 spectrometer. Measurements were made at 40°C with a peptide concentration of 4–5 mM in DMSO- d_6 . A spectral width of ~7500 Hz was used. The residual water peak in DMSO was suppressed using a presaturation pulse of 2 s duration. 2D NMR spectra, viz. DQF COSY, TOCSY and NOESY were obtained generally with 1 K complex data points, 32 transients, 256 t_1 increments and were zero filled to 2 K \times 2 K points. In some experiments the parameters were changed depending upon the requirements. Before Fourier transformation, the time domain signals were weighted by sine square or sine bell window functions in both dimensions. NOESY mixing times were optimized after doing several 2D experiments and a mixing time of 400 ms was found to be adequate. Similarly for the 2D TOCSY experiment a mixing time of 60 ms was used. All 2D NMR experiments were carried out in the phase sensitive mode and processed according to the procedure of States *et al.*

Results and discussion

The analysis of NMR spectra is based on the sequential

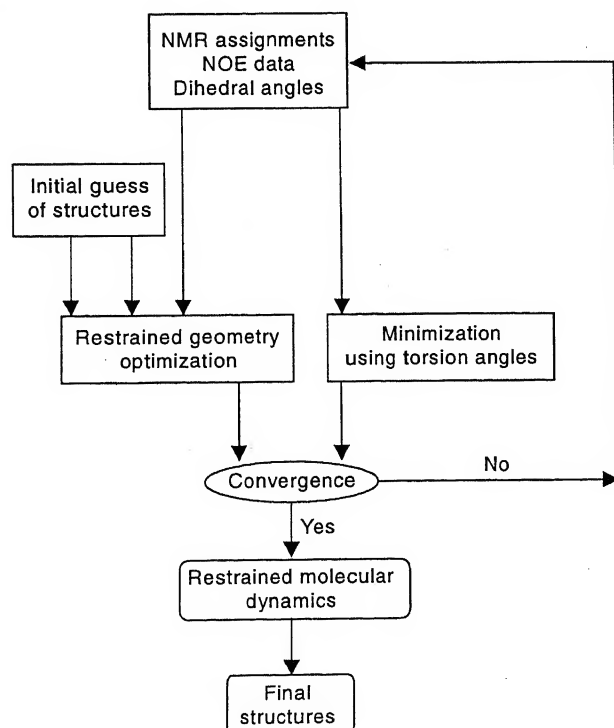

Figure 7. Flow chart for the determination of structures of peptides on the basis of NMR data.

resonance assignment procedure developed by Wüthrich *et al.*⁷⁴. This is a two-stage process. The first step involves the assignment of each cross peak in the *finger print* region to a specific amino acid type. The experiments, COSY, DQF COSY and TOCSY give information about the through bond scalar coupled spin systems. Amino acid residues with unique coupling patterns could be identified clearly whereas the other cross peaks can only be assigned to more general classes of amino acid types. Complete spin system assignment depends on the resolved coupling patterns and on the topology of the spin system under consideration. In the second stage, the cross peaks are assigned to the specific amino acid residues in the peptide sequence using NOE data⁷⁹.

Analysis of the spin systems. The peptide 1–1–1 consists of 32 amino acid residues. The DQF COSY spectrum for this peptide is shown in Figure 9a. Of the 32 residues, the finger print region clearly shows at least 22 of the NH- α CH connectivities. The remaining residues could not be located either due to severe overlap or

Steps in the structure determination of peptides by NMR

1. Sequential resonance assignment:
 - (a) Use COSY, DQF COSY, TOCSY and in some cases MQ spectroscopy to assign spin systems using through bond connectivities.
 - (b) Identify the flanking residues to a given amino acid by means of NOESY utilizing short-range connectivities.
2. Explore tertiary connectivities between non-neighbour residues through long range NOEs.
3. Estimate through space distances by quantifying NOEs into categories such as weak, medium and strong so that some distance constraints can be derived that will be useful in modelling.
4. Use the DQF COSY and other versions of COSY that allow quantitative estimates of three-bond coupling constants that will be useful to arrive at backbone torsion (dihedral) angles.
5. Look for the presence of segments of sequential connectivities that would indicate the presence of helices and probably β -sheets.
6. Finally try to arrive at the three-dimensional structure using a combination of NOE data and torsion angles in conjunction with one or more of the following approaches.
 - (a) Molecular model building packages with NOE derived distance constraints.
 - (b) Comparison with X-ray derived structures of the same peptides or homologues.
 - (c) Restrained least squares minimization in torsion angle space.
 - (d) Restrained molecular dynamics.

Figure 8.

due to the corresponding peaks being absent in the finger print region (Figure 9b). This might be due to the very low intensity arising out of a small NH- α CH coupling constant or due to the large line width. Also the overlap of antiphase components in DQF COSY spectrum leads to cancellation of most of the cross peak intensity.

The peptide 1-1-1 has 12 amino acid residues with unique spin systems, 8 of AMX type and 12 long side chain residues. There are four glycines at sequence positions 14, 16, 24 and 31. Two of the glycines are identified based on their characteristic cross peaks in the COSY spectrum. One more glycine residue, with degenerate α CH protons, is identified from the sequential NOE data. Two alanines at sequence positions 1 and 6 are identified from the COSY and TOCSY spectra. The assignment of the α CH proton is difficult due to severe overlap. One valine and all the four threonines are assigned unambiguously from the COSY and TOCSY spectra (Figure 10a, b). The identification of Ile and Leu residues is based on the appearance of the NH- δ CH₃ cross peaks. Unambiguous assignment is achieved only from the analysis of NOESY spectrum. Thus out of 15 residues of this type, 11 residues are assigned unambiguously.

The only aromatic residue present in this system is phenylalanine. Two of the three Phe are identified from the possible NOE cross peaks between the aromatic ring protons and the aliphatic protons of the same residue. NH resonance of one of the Phe is missing, but its

Figure 9a. 600 MHz phase sensitive DQF COSY spectrum of the peptide 1-1-1 in DMSO at 40°C. The COSY connectivities of valine are shown.

position is identified from the NOE data. Two serines are distinguished from the aspartate residues due to the low field resonances of β protons. Seven out of eight residues of this type are thus identified.

The long side chain spin systems were grouped into one class partly on the basis of chemical shift values of the β CH protons and partly on the patterns of the α CH- β CH cross peaks which are distinct from those of the AMX spin systems. The identification of the additional resonances belonging to the spin system helps in distinguishing the type of amino acid, i.e. lysines from glutamates, methionines, etc.

Sequential assignment. The sequential assignment of the peptide 1-1-1 dissolved in DMSO solution is based on the analysis of NOESY spectra with a mixing time of 400 ms (Figure 11a). The unambiguous assignment of the residues valine, glycine and threonine helps in the identification of the sequence position of the other residues. Analysis of the finger print region of the NOESY spectrum helps in the assignment of the peptide segments, Phe-3-Lys-4; Asp-11-Lys-12-Asp-13-Gly-14-Asp-15; Gly-16-Thr17; Gly-24-Thr25; Val-26-Met-27. The peak position of the Phe-3 is located on the basis

REVIEW ARTICLE

of its NOE with Lys-4. The other two phenylalanines are at positions 7 and 10. The residue at position 10 is identified on the basis of the NOE cross peak between the ring proton and the γ CH proton of Leu-9. Thus all

the three phenylalanines are located clearly. Analysis of the NH-NH region of the NOESY spectrum (Figure 11 b) confirms the sequential assignment. The residue Leu-23 is assigned based on the NH-NH cross peak between

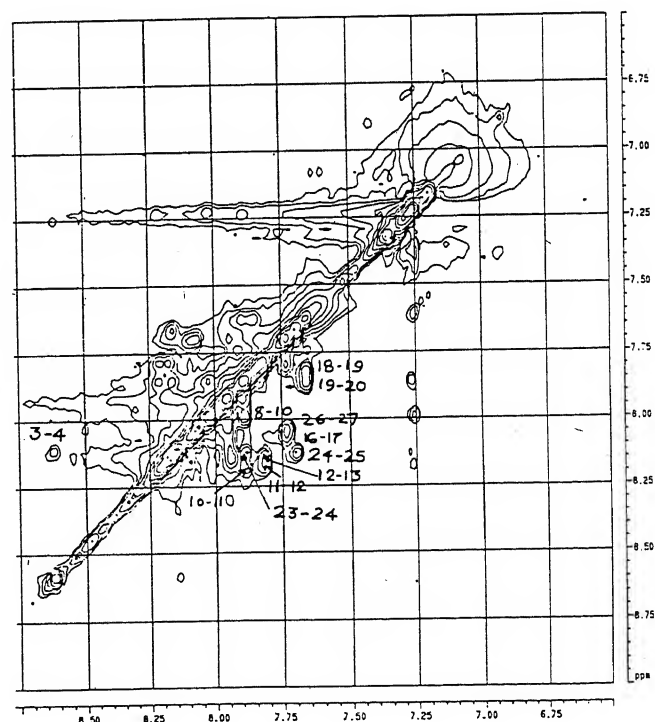

Figure 11 b. The amide region of the NOESY spectrum of the peptide 1-1-1.

Leu-23 and Gly-24. The unambiguous assignment of the two lysines, at sequence positions 4 and 12 enables the assignment of the remaining one to Lys-21. The presence of weak NH-NH cross peak between Lys-21 and another long side chain containing residue, helps in the assignment of Glu-22. Identification of the Leu-9 and Leu-23, made the assignment of the remaining leucine residue to Leu-30. A summary of through space connectivities inferred from 2D NOESY for the peptide 1-1-1 is given in Figure 12.

Secondary structural elements. The presence of strong NH-NH connectivities from the Phe-10 to Asp-15 and Gly-16 to Thr-20 indicates that the peptide exhibits helical structure in these regions. The NH resonance of all the three aspartates appears almost close to each other, making the assignment of the $\alpha\text{CH}_i\text{-NH}_{i+3}$ cross peaks between the residues, Asp-11-Gly-14; Lys-12-Asp-15; and Asp-13-Gly-16, difficult. The absence of $\alpha\text{CH}_i\text{-NH}_{i+3}$ for the peptide segment Gly-16 to Thr-20, indicates that this part is characterized by a loose helical segment. The strong $\alpha\text{CH}_i\text{-NH}_{i+1}$ and a weak $\alpha\text{CH}_i\text{-}\alpha\text{CH}_{i+1}$ between Asp-11 and Asp-15 indicate the possibility of an extended structure. Careful analysis of the $\alpha\text{-}\alpha$ region shows only three distinct binary connectivities among residues 14-15, 24-25 and 8-9. In view of this lack of contiguous connectivity it is clear that the system, although may exist transiently as an anti-parallel β -sheet, the average conformation is more like an extended structure. All these point to a possible conformational equilibrium between an extended and

helical structure. This fact is again supported by the presence of weak sequential $\alpha\text{CH}_i\text{-}\alpha\text{CH}_{i+1}$ connectivities for the residues Lys-12 to Asp-15. The presence of strong $\alpha\text{CH}_i\text{-NH}_{i+1}$ and $\text{NH}_i\text{-NH}_{i+1}$ cross peaks between the residues Phe-3-Lys-4; Gly-24-Thr-25; and Val-26-Met-27 indicates the possibility of a turn structure. The presence of $\text{NH}_i\text{-NH}_{i+2}$ and $\beta\text{CH}_i\text{-NH}_{i+2}$ connectivities between the residues Phe-7 and Phe-10 indicates the existence of a β -turn structure in this region. The end residues are not well characterized due to lack of NOE information.

Summary and conclusions

A brief summary of the approach to the elucidation of 3D structure of fair-sized peptides using high resolution 2D NMR techniques has been presented and the procedure is illustrated with a small 32-residue peptide corresponding to the first calcium-binding domain of the protein calmodulin. Whereas this part in the crystal of the native molecule has a clear cut helix-loop-helix (EF motif) configuration, fragmentation has led to a large reduction in the secondary structure. It is unfortunate that the solubility of the fragment has been so low that the experiments had to be carried out in DMSO solution. Often NMR methods are supplemented with other experimental techniques such as circular dichroism, Fourier far IR and Raman spectroscopy. The results obtained are used as input into molecular modelling and molecular dynamics calculations¹⁹⁻²³ where the NMR NOEs can be used to provide certain constraints in

REVIEW ARTICLE

interatomic distances so as to arrive at plausible structure in an expeditious way. Caution has to be exercised in using the NOE data when one suspects rapid interconversion between conformers.

All India Institute of Medical Sciences Ansari Nagar, New Delhi 110 029

Training in Electron Microscopy for (1) Laboratory/Technical Staff and (2) Scientific Investigators

Two training programmes in Electron Microscopy (Biomedical Sciences) will be held for the 2 above mentioned categories of personnel during 1996-1997.

Category I: Laboratory/Technical Personnel: 26 Nov. to 10 Dec. 1996 (15 days);

Category II: Scientific Investigators: 6 Jan. to 27 Jan. 1997 (21 days).

Eligibility

Category I: B Sc degree and/or Diploma in MLT with minimum of 2 years experience in light microscopy. Number of seats are limited. Fee Rs 1000.

Category II: PhD/MD or M Sc degree with 2-3 years of research experience. The applicant should state clearly the nature of the research project in which he/she is involved (in 200 words) and why training in Electron Microscopy is necessary for pursuing further research. Number of seats are limited. Fee Rs 3000.

Application on plain paper giving the following: (1) Name, (2) Age, (3) Postal address (fax number, if available may be indicated), (4) Sex, (5) Educational qualification, (6) Name of the University/Institution, (7) Year of passing, (8) Marks obtained, (9) Position(s) held, (10) Whether permanent/temporary, and (11) Letter of recommendation from the present employer, should reach Dr A. K. Susheela, Officer-in-Charge, Electron Microscope Facility, Department of Anatomy, AIIMS, New Delhi 110 029 (Fax: 686 2663) **latest by 5 November 1996.**

Selected candidates will be informed latest by 11 November 1996, when the Course fee should be remitted. Details will be provided in the Selection Letter.

Patterns of distribution of macrolichens in western parts of Nanda Devi Biosphere Reserve

Hans Raj Negi¹ and Madhav Gadgil^{1,2}

¹Centre for Ecological Sciences, Indian Institute of Science, Bangalore 560 012, India

²Biodiversity Unit, Jawaharlal Nehru Centre for Advanced Scientific Research, Jakkur P.O., Bangalore 560 064, India

A total of 76 species of macrolichens were recorded from 16 transects of 50 m × 10 m between altitudes of 2100 m and 4500 m in western parts of Nanda Devi Biosphere Reserve of Garhwal Himalayas. Forty-one of these are lignicolous species occurring on woody, 14 are terricolous growing on soil and 10 are saxicolous inhabiting rocks only. The other 11 species occur on more than one major types of substrate. Lichen species diversity is at its highest in middle altitudes between 2700 m and 3700 m where all three major substrates are simultaneously available. Lichen species diversity of Nanda Devi Biosphere Reserve appears to be under threat from deforestation and fires, as well as from loss of soil microhabitats due to overgrowth of weeds seemingly caused by cessation of summer grazing in alpine pastures.

LICHENS, the most successful of symbiotic organisms on earth, constitute the dominant life form over as much as 8% of earth's surface¹. They are amongst the most significant bioindicators²⁻⁶ besides having many economic applications^{7,8}. While there have been some systematic studies of the 697 species rich macrolichen flora of India⁹, there have been no investigations of their community ecology. We report here the first such community level study from the western parts of Nanda Devi Biosphere Reserve (NDBR) (30°30' to 30°38' N latitudes and 79°44' to 79°46' E longitudes). The entire biosphere reserve extends over an area of 2236.74 sq km in the upper reaches of Garhwal and Kumaon Himalayas spanning an altitudinal range of 1000 m to 7817 m. Our study area falls within the range of 2100 m to 4500 m above mean sea level in the landscapes of the Garhwal Himalayas with an estimated area of 500 sq km (ref. 10) (Figure 1). This rugged mountainous landscape includes crystalline rocks belonging to Vaikrita Group and lower parts of the Tethys sediments along the river Rishi Ganga¹¹. Although there are no records, precipitation is estimated to range over 1000 mm–1500 mm per year including heavy snow fall during December to March. Except alpine meadows, all other study sites are exposed to various levels of human interferences including grazing and fuel wood collection.

Methodology

Lichen communities were investigated in the western parts of NDBR over an altitudinal range of 2100 m to 4500 m during September–October 1993. Since a large part of study area falls within core zone of the reserve, administrative and logistic constraints did not allow us to sample areas above 4500 m. The sampling method involved laying down 16 transects of 50 m × 10 m in different localities covering temperate pine forest, sub-alpine birch-rhododendron forest and alpine meadows along with road-side grass and scrub at the lower altitude. A thorough search of 500 sq m transect consumed between 1 and 4 hours. Records were maintained of macrohabitat types, mesohabitat conditions with respect to exposure to sun, exposure to wind, habitat slope and humidity as well as of microhabitats of all the lichen colonies encountered (Table 1). These include three major substrates, viz. rocks, soil and wood; with further discrimination of 9 soil microhabitat types and 31 types of microhabitats in relation to species-specific wood, position on a tree and whether the wood is live or dead (Table 2). Mesohabitat levels were assigned on the basis of ordinal scaling whereas the macrohabitat types were nominally categorized¹² based on the ground vegetation. While lichens could not be sampled on trees above a height of 2.5 m, many canopy species were encountered through collection of fallen branches and twigs on the ground.

Results and discussion

Lichen flora

A total of 76 species belonging to 24 genera and 18 families constituted the macrolichen community of the western part of NDBR occurring in 204 colonies over the 8000 sq m sampled¹³ (Table 3). Figure 2 shows levels of species richness in our study area along with 8 other investigations in different parts of the country¹⁴⁻¹⁷. Evidently our sampling has yielded a higher level of species diversity in relation to the area sampled compared

RESEARCH ARTICLE

Cladonia coniocraea, abundantly encountered macrolichen occurring on soil as well as wood substrates.

Rhizocarpon geographicum, abundantly found microlichen species only grow on rocks.

Lichens of genus *Parmelia* growing on tree trunk bark at 2500 m.

Lichens are the dominant forms of life on the exposed rocks in the higher reaches of Nanda Devi Biosphere Reserve.

Xanthoria elagans, a colourful lichen growing on rocks at 4000 m.

Birch tree supporting a luxuriant growth of longest of lichen thalli of *Usnea longissima*.

to other studies reported from India. Figure 3 shows the patterns of relative abundance of the species showing that most species were encountered in 1 to 4 colonies only. *Cladonia coniocaea* was the most abundant of all the species.

Niche-width of species computed as Shannon-Wiener index¹⁸ with respect to fine divisions of the substrates (microhabitats) is, as expected, positively correlated with

the number of colonies encountered. After correcting for this factor, *Parmelia cirrhata* emerges as a significantly broad niched species while *Dermatocarpon velterium* and *Umbilicaria indica* as two significantly narrow niched species with respect to their fine microhabitat preference (Figure 4). Nine of the 20 more abundant species occurring in four or more colonies occupy two out of three major substrates, and may therefore be

Table 1. Details of locality, macrohabitat, mesohabitat, major substrates, macrolichen abundance and species richness for the sixteen 50 m x 10 m transects

Locality	Altitude (m)	Macrohabitat	Mesohabitats				Major substrates	No. of colonies	No. of species	Significance
			Sn	Wn	Slp	Hm

considered as broad niched in this context. These include, *Stereocaulon foliolosum*, *Stereocaulon glareosum*, *Cladonia coccifera*, *Phaeophyscia hispidula*, *Cladonia coniocraea*, *Ramalina pollinaria*, *Menegazzia terebrata*, *Ramalina roesleri* and *Cladonia rangiformis*.

Species diversity

Table 2 provides details of the 16 sites in terms of macrohabitat type, altitude, mesohabitats and major substrates. The species richness or α -diversity of these sites was compared through rarefaction¹⁹. On this basis we can assign significantly high levels of species richness at 1% level to 5 sites, viz. Belta at 2700 m, Dibrugghetta at 3400 m, Latakharak at 3600 m and 3700 m and Dhoni-dhar at 3800 m. Notably enough, four of these species-

rich sites harbour all the three major types of substrates.

Species turnover or β -diversity defined as unshared species as a proportion of total species at any two different sites is another component of species diversity²⁰. This is equivalent to 1-Jaccard co-efficient of similarity employed in the complete linkage dendrogram²¹ of Figure 5. It is evident that turnover increases with altitudinal difference. Although microhabitats and mesohabitat conditions at the lowest altitudinal site were similar with alpine meadows, this site separates out because of a distinctive species composition. This may be attributed to the substantial altitudinal difference coupled to human disturbance and air pollution on the road side. The three transects at the same altitude of 3700 m varied in species composition, presumably because of differences in macro-habitat and mesohabitat conditions (Table 1).

Table 3. Macrolichen species, with abbreviated family name in brackets, of western parts of Nanda Devi Biosphere Reserve, arranged in order of decreasing abundance on the three major substrate types, viz. rock, soil and wood

‘+’ indicates significantly broad and ‘-’ indicates narrow niche with respect to fine microhabitat preference.

‘++’ indicates broad niched with respect to their occurrence on the major substrates.

Full names of families: {Can}, Candelariaceae; {Cla}, Cladoniaceae; {Col}, Collembataceae; {Hyp}, Hypogymniaceae; {Lec}, Lecanoraceae; {Lob}, Lobariaceae; {Nep}, Nephromataceae; {Par}, Parmeliaceae; {Pel}, Peltigeraceae; {Phy}, Physciaceae; {Ram}, Ramalinaceae; {Sip}, Siphulaceae; {Ste}, Steriocalaceae; {Sti}, Stictaceae; {Tel}, Teloschistaceae; {Umb}, Umbilicariaceae; {Usn}, Usneaceae; {Ver}, Verrucariaceae.

Figure 4. Relationship between the number of colonies encountered and the niche-width of the species with respect to microhabitat usage. The graph also shows the fitted regression line and lines representing confidence intervals at $P < 0.01$. The numbers correspond to the order in which species are listed in Table 3, indicating that *Parmelia cirrhata* has significantly broadened niche and *Umbilicaria indica* and *Dermatocarpon vellereum* have significantly narrow niche-width.

Niche-overlap

Niche-overlap with respect to microhabitat usage was computed based on Pianka's measure of niche-overlap²². Figure 6 based on complete linkage analysis²¹ depicts the clustering of 20 species occurring in four or more colonies with respect to their preference for the 41

Figure 5. Complete linkage dendrogram of 16 sites based on Jaccard's co-efficient of similarity with respect to composition of species.

microhabitats. The species tend to cluster with respect to the major substrates which are evidently critical in determining the distribution of macrolichen species.

Microhabitat preference

Although woody microhabitats were restricted to 10 out of 16 transects, a majority of the species were found to be favouring wood. Figure 7 is a Venn diagram of microhabitat preference of 20 more abundant as well as 76 total species. These bring out the importance of woody microhabitats in promoting lichen species diver-

Figure 6. Complete linkage dendrogram for 20 species occurring in 4 or more colonies based on Pianka's measure of niche-overlap with respect to microhabitat usage.

More abundant 20 Species

Total 76 Species

Figure 7. Venn diagram of distribution of a total 76 and of 20 more abundant macrolichen species on the three major substrates.

sity. However there are a number of species confined to soil and rocks as well.

Conservation implications

Deforestation, excessive fuelwood collection and fire²³, all adversely affecting wood loving species of lichens appear to be major threats to the rich macrolichen flora of the Himalayas. Although firm evidence is lacking, it is also possible that the ban on summer grazing in the alpine meadows of NDBR may be adversely affecting macrolichen diversity, since this cessation of grazing has led to spread of weedy species like *Rumex nepalensis*

and *Phlomis bracteata* and shrinkage of soil microhabitats of the lichens. The rich macrolichen flora of Himalayas could play an important economic role as well. Species of *Ramalina*, *Parmelia*, *Usnea* and *Evernia* are a source of essential oils widely used in health care and perfumery industry⁷. Lichen thalli, a rich source of nitrogen²⁴, has promise as a source of organic manure, although today it is being wasted along with fire wood.

Transformation of *Streptococcus* sp. by cholera toxin gene

Swadesh R. Biswas, Sukanya Pal, Sukanta K. Sen and Sushil C. Pal

Department of Botany, Visva-Bharati, Santiniketan 731 235, India

Calcium chloride-treated cells prepared from *Streptococcus* sp., a curd-forming bacterium isolated from whey, were transformed by pCVD15 DNA containing the cholera toxin gene. The transformants conferred resistance to ampicillin and chloramphenicol. Transformation efficiency was slightly higher for the competent cells than for the incompetent cells. The *Streptococcus* cells were found to be naturally competent.

CHOLERA is a life-threatening infectious disease caused by *Vibrio cholerae* colonizing the small bowel and secreting enterotoxin – cholera toxin – that leads to diarrhoeal disease characterized by profuse water loss. Cholera toxin consists of a single A subunit (27 kDa) and 5-B-subunit (11.6 kDa)¹ which binds to the GM ganglioside receptor of intestinal mucosal cells^{2,3}. This binding can be prevented by antibody against B-subunit^{4,5}. Thus B-subunit of cholera toxin gives protection against *V. cholerae* when antibody is located in the lumen of the intestine⁶. Circulating antibody has been proved to be ineffective in giving protection. However, protection by B-subunit is of short duration (few months). Attempts to administer vaccine orally has been unsuccessful because of lack of colonization ability of the strain⁷. For effective use of B-subunit as vaccine the gene has been cloned in *E. coli*⁸, though the extraction and purification costs are very high. Recently trial is being made to inactivate the cholera toxin gene by modifying amino acid residues at positions 7 and 112 of cholera A subunit for use as oral vaccine by exchanging this modified toxin gene to the wild type strain⁹.

An effective way has been devised by Haq *et al.*¹⁰ by making transgenic plant as expression and delivery system for oral vaccine. Plants have expressed the B-subunit gene and feeding of such transgenic potatoes to mice induced protection to treated mice against cholera.

In an alternative way we have devised a system for delivery of oral vaccine against diarrhoeal disease through gram-positive lactic acid curd-forming bacterium *Streptococcus* sp. isolated from whey. Since the nontoxicogenic *V. cholerae* with only B-subunit gene incorporated into its chromosome does not colonize permanently in the intestine⁷, gram-positive bacteria can be tested for this purpose. Lactic acid curd-forming bacteria are safe to eat through curd. Moreover, no extraction and puri-

fication of vaccine is needed. Frequent consumption of curd by this recombinant cultures will maintain the availability of vaccine in the lumen. Also the vaccine can be made at home by making curd, and in our laboratory it has been shown that curd, using this culture, can be made within 4 h. No data, however, is available whether this bacterium does colonize in the intestine.

In this study, *Streptococcus* sp. was transformed with recombinant plasmid pCVD15⁷ containing the entire cholera toxin gene⁷. The transformants conferred resistance to ampicillin and chloramphenicol and had the ability to make curd. This result suggests that both the antibiotic genes have been expressed in *Streptococcus* sp. Since this plasmid does not replicate in gram-positive bacteria, it may be assumed that the plasmid has integrated into bacterial chromosome. Plasmid preparation from the transformant colonies in the presence of antibiotics was done and no plasmid of 18 kb (pCVD15) was found. The number of transformants (2×10^4 μ g CsCl purified pDNA) indicates that this strain shows high frequency of gene transfer and thus can be manipulated genetically.

The working strain was found to be naturally competent. Transformation frequency of *Streptococcus* cells grown in TGE medium¹¹ was 1.5×10^4 (Table 1) whereas it is 2×10^4 when cells were made competent (CaCl method)¹². This observation was verified by transforming both competent and incompetent cells of *Streptococcus* with pUC19 DNA containing ampicillin resistance gene. The transformation frequency was higher for pUC19 DNA than for pCVD15 (Table 1). The mechanism of genetic exchange was proved to be dependent upon uptake of free DNA since no transformants were observed when 20 μ g of pancreatic DNase (in 5 μ l of 0.02 M MgCl, 0.02 M maleate, pH 6.5) was added to transforming DNA one hour before transformation. The transformants were destroyed after completion of experiments as safety measure.

Work is in progress to find out whether the toxin

Occurrence of a 'mariner' element in the silkworm *Bombyx mori*

S. Mathavan, S. Mayilvahanan and A. Jeyaprakash*

Department of Genetics, School of Biological Sciences, Madurai Kamaraj University, Madurai 625 021, India

*Department of Entomology and Nematology, University of Florida, Gainesville, Florida, USA

Occurrence of mariner element in *Bombyx mori* is reported here for the first time using degenerate primers in polymerase chain reaction (PCR) technique. The PCR product (Bm.MAR1) has been cloned and sequenced; it is 457 bp in length. DNA and peptide sequences of *Bombyx* mariner show a high degree of similarity with the mariner of the predatory mite, *Metaseiulus occidentalis* and low degree of similarity with the lepidopteran *Hyalophora cecropia*. Since no transcripts could be identified for the mariner of *B. mori* in northern hybridization, it appears to be a transcriptionally defective element.

SINCE McClintock¹ discovered mobile genetic element in maize, presence of such transposable elements has

been reported from a number of other eukaryotic genomes². A new transposable element 'mariner' has been identified and cloned from an unstable white mutant of *Drosophila mauritiana*, a sibling species of *D. melanogaster*³. The original mariner element is 1286 bp in length having 28 bp inverted repeats and an open reading frame (ORF) coding for a polypeptide of 345 amino acids. It is functional for germline transformation of *Drosophila*³. Lidholm *et al.*⁵ identified a mariner element in *Hyalophora cecropia* and showed about 40% DNA sequence identity with *Drosophila* mariner element. Using degenerate PCR primers, Robertson⁶ has shown the widespread occurrence of mariner elements in insects (17% among 400 species screened). Using the same PCR primers, Jeyaprakash and Hoy⁷ cloned a mariner element from a predatory mite *Metaseiulus occidentalis* and showed the presence of functional open reading frame. They constructed a transformation vector containing the mariner and made stable transformation of the predatory mite. Despite the fact that more than 400 species have been screened, the presence of mariner elements in the silkworm *Bombyx mori* has not been detected. This paper is the first report on the occurrence of mariner elements in *Bombyx mori*.

Bombyx mori strains (NB₄D₂, NB₁₈, KA, NB₇) were obtained from the Central Sericultural Research and Training Institute, Mysore. The genomic DNA isolation (from larval fatbody cells) was performed as described by Sambrook *et al.*⁸

The PCR was carried out using degenerate primers [MAR124F-5'-TGGGTNCCNCAYGARYT (17-mer) and MAR276R-5'-GGNGCNARRTCNGGNSWRTA (20-mer)⁶]. The conditions for PCR were: *Taq* polymerase buffer (1x), 2.5 mM MgCl₂, 150 µM dNTPs, 800 nM each primer, 0.25 units *Taq* polymerase, and 1-100 ng genomic DNA in a 25 µl total reaction volume⁹. For 35 cycles, amplification conditions were: denaturation at 94°C for 30 sec, annealing at 48°C for 30 sec and extension at 74°C for 1 min in Perkin-Elmer Thermol cycler. An aliquot from each reaction (10 µl) was electrophoresed on a 2% TBE gel. The amplified PCR product was purified by electro-elution and cloned into 'T' tailed plasmid. The clone was termed as pBm.MAR1.

The recombinant plasmid containing pBm.MAR1 was isolated and purified following standard methods⁸. The recombinant plasmid was transformed into *E. coli* strain DH5α; the plasmid DNA was isolated, purified and sequenced by conventional dideoxy method in an automated sequencer¹⁰. The sequence of *B. mori* mariner element was translated and compared with the translated sequence of mariner element of other species using the software 'GCG' (Genetic Computer Group, Wisconsin-Madison, USA)¹¹. Mariner sequences of other species were recovered from 'EMBL Gene bank' for comparison.

Using degenerate primers (MAR124F and MAR276R)

Figure 1. PCR amplification of mariner element from four different strains of *Bombyx mori* using degenerate primers (MAR 124F and MAR 276R). The samples in the lanes are: 1) λ marker; 2) No DNA control; 3) 100 ng, 4) 10 ng and 5) 1 ng of NB₄D₂ genomic DNA used for PCR; 6) 100 ng, 7) 10 ng and 8) 1 ng of NB₁₈ genomic DNA used for PCR; 9) 100 ng, 10) 10 ng and 11) 1 ng of KA genomic DNA used for PCR; 12) 100 ng, 13) 10 ng and 14) 1 ng of NB₇ genomic DNA used for PCR.

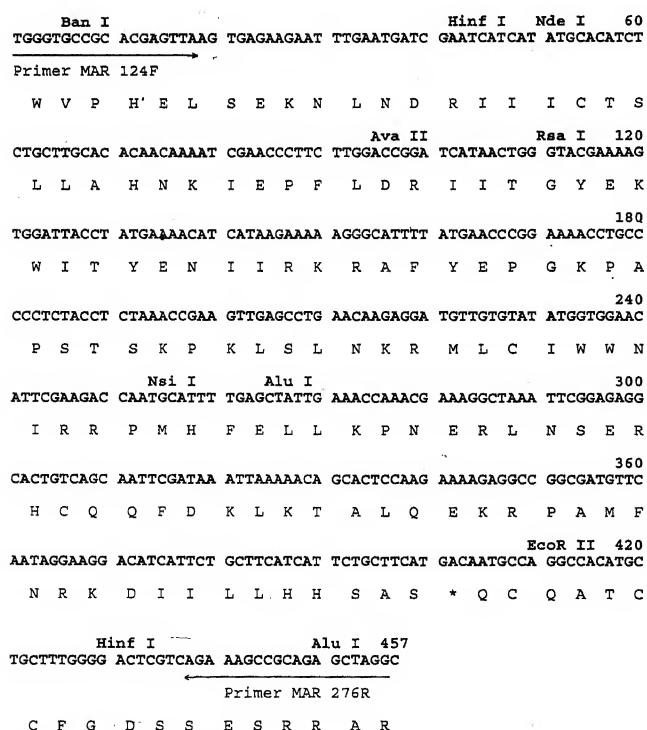

Figure 2. The PCR amplified *B. mori* mariner (Bm.MAR1) sequence was cloned and sequenced. The restriction map and amino acid sequence of Bm.MAR1 are shown.

PCR amplification of genomic DNA from *B. mori* strains resulted in the production of a single fragment approximately 450 bp. The PCR products obtained in all the four strains were identical in size (Figure 1). The PCR product was equal in size to the mariner product amplified in *D. mauritiana* using the same primers⁶. The PCR product from *B. mori* represents internal sequence of the mariner and the purified product was cloned. Six clones were obtained from the PCR product amplified from *B. mori* strain NB₇, and all the clones showed identical size on agarose gel fractionation. One of the clones was completely sequenced and it contained 457 base pairs (Figure 2). The possible existence of an ORF was tested in all the three frames. There were a number of stop codons in the second and third frames, while there was one stop codon in the first reading frame at 399 bp. The 457 bp pBm.MAR1 was compared with PCR-amplified clones (using the same primers) of mariner from *Hyalophora cecropia*, *Anopheles gambiae*, *Haemaphysa irritans*, *Metaseiulus occidentalis* (using 'GAP' software of GCG) and the data is presented in Table 1. The mariner sequences of the above species were translated into amino acid sequences and aligned using Clustal V multiple sequence alignment program of GCG software (Figure 3). Peptide similarity and identity of the mariner from these species were compared. *M.*

Figure 3. Alignment of translations of mariner PCR fragments from *D. mauritiana*, *H. cecropia*, *A. gambiae*, *H. irritans*, *M. occidentalis* and *B. mori*. They were translated using 'GCG' software; the '-' symbol indicates frameshift to maintain an aligned reading frame and the asterisk indicates stop codon. The translations were aligned using Clustal V multiple sequence alignment program with final manual alignment.

Table 1. Comparison of Bm.MAR1 sequence with mariner elements of other species. The mariner sequences were retrieved from 'EMBL' data bank and compared using 'GAP' program of 'GCG' software

Species	DNA sequence identity (%)	Peptide similarity (%)	Peptide identity (%)
<i>D. mauritiana</i>	57	52	39
<i>H. cecropia</i>	47	44	25
<i>A. gambiae</i>	39	46	24
<i>H. irritans</i>	41	48	27
<i>M. occidentalis</i>	49	57	41

occidentalis showed maximum peptide similarity (57%) with *B. mori* mariner sequence, and minimum similarity was noted with *H. cecropia* (44%). In peptide identity, the maximum similarity was observed with *M. occidentalis* and minimum with *A. gambiae*. Though *B. mori* and *H. cecropia* belong to the same order Lepidoptera, their mariner elements are diversified. The mariner element of *B. mori* appears to be close to *M. occidentalis* or *D. mauritiana*.

The northern blot of total RNA from *B. mori* was probed with Bm.MAR1. No detectable signal was obtained, indicating the absence of mariner specific mRNA population. Since there was a break in the coding sequence of *B. mori* mariner, it was found to be a defective mariner. Possible use of the mariner for the construction of vector for a stable germline transformation of *B. mori* needs to be confirmed only after cloning and sequencing of a number of mariner elements from more silkworm strains (both mulberry and non-mulberry

silkworms). This is the first report on *B. mori* mariner and cloning of full length mariner from other strains is under progress.

Methane production by Indian ruminant livestock

G. P. Singh and Madhu Mohini

National Dairy Research Institute, Karnal 132 001, India

Methane production estimates for Indian ruminants by various outside agencies were much higher^{1,2} because the estimates were based on theoretical calculation without any actual experimentation on Indian ruminant livestock. The total methane contribution to greenhouse pool by Indian ruminants was 9.02 Tg/year based on methane production per kg digestible dry matter of feed available in different parts of the country and determined at National Dairy Research Institute, Karnal. Similarly, the methane production per kg milk produced in India was also much lower than reported earlier³.

CARBON DIOXIDE, methane, chlorofluorocarbons (CFCs), nitrous oxide and other gases like sulphur hexafluoride etc. are the main greenhouse gases accumulating in the atmosphere due to the process of industrialization. This is causing depletion of ozone layer and global warming. It has been projected that if the present state of industrialization, dairy farming, growing of paddy, etc. con-

tinue, the concentration of carbon dioxide in atmosphere will double⁴ by 2055 AD and concentration of greenhouse gases from all sources (carbon dioxide, methane, nitrous oxide, CFC, etc.) will double⁵ by 2035 AD. Methane emission in atmosphere as a greenhouse gas has been estimated to be 255 million tonnes per year², although, Reid⁶ estimated 423 million tonnes per year. Methane contribution to greenhouse gas pool is only 18%, however, its production by ruminants is one of the major global issues because of its relative effectiveness in terms of global warming potential and life in atmosphere. One kg methane's relative effectiveness in terms of global warming potential is equal to 40 kg carbon dioxide. According to an estimate², Indian contribution of methane from all sources is 12.1% of total world methane production and out of that rice field and ruminants contribute 27.3 and 13.2%, respectively, of total Indian methane production. Various methods are suggested for reducing the methane production by ruminants, however, control of methanogenesis by manipulation of rumen fermentation through feed additive and feeds is the only feasible and attractive solution at present^{7,8}. Acetate and butyrate are methanogenic and spare hydrogen during their formation, while propionate being the glucogenic VFA utilizes hydrogen. Therefore, molar percentage of acetate, propionate and butyrate in TVFA play an important role

Table 1. Methane production by Indian ruminant livestock (cattle, buffalo, sheep and goat)

Species	Methane production			
	Number ($\times 10^3$)	l/day ($\times 10^6$)	mole/day ($\times 10^8$)	Tg/year

Body weight of animal.

Type of feed and intake.

Digestibility of feed.

Methane per kg DDM determined.

Figure 1. Contribution of methane by different ruminant livestock.

Figure 2. Methane production by Indian ruminant per kg milk produced based on total milk production and population.

in methane production by ruminants and proportion of these in rumen needs to be manipulated.

Total gas production was measured as proposed⁹. At the same time, *in vitro* dry matter digestibility (IVDMD) (single stage) of the samples of feed and fodders along with their combinations as practised in various parts of the country were also estimated for calculating the gas and methane production per unit of digestible dry matter (DDM). Percentage of methane in gas was estimated by absorbing carbon dioxide in 1 N sodium hydroxide, and making necessary correction for some other minor gases present in ruminal gas pool. Methane production per kg digestible dry matter was estimated for different types of ration based on IVDMD and methane produced on fermentation of feed. Thus, methane production based

on per unit feed fermented is comparatively a better method of assessment of methane production. On the basis of methane produced per kg DDM, methane production per day for different categories of animals was calculated taking into account the intake and digestibility of feed by the animals. Total methane production by Indian ruminant livestock has also been calculated.

In rural areas of India, animals are not fed in keeping with their requirements. Most of the animals are underfed during scarcity period of the year. Feeding practices and type of feed differ from region to region. Even the body weight of animals is not the same and varies. Taking into account all these factors total emission of methane from ruminant livestock has been calculated (Table 1). Total emission of methane by cattle is 5.690 Tg/year, with the male contributing 3.088 Tg/year, and female 2.602 Tg/year. Buffaloes contribution of methane to atmosphere is estimated to be 2.735 Tg/year, with male buffaloes contributing only about 18%. Sheep and goat's contribution to total methane pool is 0.210 and 0.388 Tg/year. The per cent share of total methane production was much higher in cattle than the total of buffalo, goat and sheep (Figure 1) because of their numbers, body weight and amount of feed consumed.

Contrary to the amount of methane emission by Indian ruminant livestock observed on the basis of experimental data by the authors, higher amount of methane emission (10.0 and 10.4 Tg) was reported^{1,2} in 1990 on the basis of theoretical calculation. On the other hand, much lower amount of methane emission has been reported¹⁰ which was based on the prediction equation developed in Western countries, feeding grain and high quality hay diet¹¹. This is not applicable to Indian animals because Indian ruminant animals are fed on crop residues-based diets and that too is not enough to meet the nutrient requirement of more than 90% of animals.

In India, the average milk production is not more than three kg per animal per day and despite large numbers of animals majority of them are either non-producers or very low producers. Methane production per kg milk produced in India (total methane produced/total milk production), reported and discussed in many National and International fora, seems to be higher than what is actually produced, (240 g methane per kg milk)³. Methane production per kg milk varies between 148 and 183 g/kg milk (Figure 2) based on milk production and methane production estimates of last 6-7 years. However, it is far less than the reported figure of 240 g/kg.

Mutants resistant to foliar diseases in groundnut (*Arachis hypogaea* L.)

B. N. Motagi, M. V. C. Gowda and R. Sheshagiri

Department of Genetics and Plant Breeding, University of Agricultural Sciences, Dharwad 580 005, India

Foliar diseases particularly leafspots and rust are the major factors limiting yield and quality in groundnut. Most of the groundnut cultivars in India are highly susceptible to foliar diseases. Fungicidal sprays are effective in controlling these diseases, but the use of disease-resistant cultivars is a better approach. A number of resistant germplasm lines are available but many other undesirable attributes limit their utility as cultivars. Attempts have been made to produce high yielding disease resistant cultivars through hybridization, but the lines developed either had only moderate resistance or retained one or more undesirable features. Mutagenic treatment of Valencia 1 with EMS, resulted in isolation of a large number of foliar disease-resistant mutants. Three mutants, viz. 28-2, 45 and 110 combined high yield potential and early maturity, besides multiple disease resistance and desirable pod and kernel features. These mutants can be widely tested for their commercial release and/or profitably utilized in future breeding programmes.

THE cultivated groundnut (*Arachis hypogaea* L.) is an important oilseed crop and is presently cultivated in an area of 21.17 m ha with a total production of 25.89 m t. In India groundnut occupies 31.3 per cent of the total

cropped area under oilseeds (8.35 m ha) and accounts for 36.1 per cent of total oilseed production (8.85 m t). Like in other developing countries, the average yield in India is around 1000 kg per ha as against the average of 2995 kg per ha realized in USA¹. Many reasons are ascribed to the low productivity in developing countries. Foliar diseases particularly early leafspot (*Cercospora arachidicola* Hori.), late leafspot (*Phaeoisariopsis personata* (Berk and Curt) V. Arx) and rust (*Puccinia arachidis* Speg.) are the major factors limiting yield and quality in groundnut. Each of these diseases is individually capable of causing substantial yield loss, and when leafspots and rust occur together yield losses can go up to 70 per cent². These diseases have an adverse influence on the recovery of pods at harvest, quality of seeds, and haulms. Fowler³ estimated that defoliation of leaflets may begin when six per cent of their leaf area is diseased. Severe infections may cause complete defoliation. However, lesions are not confined to the leaves but may occur also on the stems and pegs, leading to direct deterioration of the developing pods⁴. Because of prolonged wet periods, late leafspot is more predominant in the transitional belt of Karnataka, which accounts for over 50 per cent pod and fodder yield loss⁵. Spanish cultivars are the most popular cultivars in this regions as they mature early and facilitate double cropping under rainfed conditions. But all of them are highly susceptible to the foliar diseases. Though several effective chemicals are available to control these diseases, fungicidal control is not preferred due to the escalation of production cost, especially in the rainfed condition⁶. Cultivation of the resistant/tolerant varieties is the best approach under these circumstances.

Several genotypes resistant to late leafspot and rust have been identified. But most of them belong to the Valencia group and are landraces with a number of undesirable attributes like thick shell, low productivity, late maturity and poor adaptation, making them unsuitable for direct utilization^{7,8}. A number of attempts have been made to produce disease-resistant, productive cultivars through hybridization, but the lines developed either possessed only a moderate level of resistance or retained one or more undesirable features⁹. A number of wild *Arachis* species have shown either highly resistant or immune reaction to these pathogens¹⁰. *A. cardenasii*, a diploid species, was identified to be an excellent source of resistance to late leafspot⁹. Stable interspecific hybrid derivatives belonging to *Virginia* group with high yield and high level of resistance have been developed but they were all late maturing and had low shelling percentages¹¹. Recently two moderately resistant hybrid derivatives, viz. ICGV 86590 and ICGV 87160 were released for commercial cultivation in southern peninsular region of India. They are comparable to popular susceptible cultivar JL 24 in productivity, but suffer from

low shelling outturn, undesirable pod features besides slightly late maturity¹². Hence, there is a strong need to develop and identify new germplasm combining high level of resistance, early maturity, desirable pod and kernel features, besides increased productivity in groundnut. But the information so far available points to the existence of a yield/resistance barrier¹³.

Induced mutagenesis offers an opportunity to artificially create desirable variation. Artificial mutagenesis of Dharwad Early Runner (DER), a stable genotype, with ethyl methane sulphonate (EMS) in our laboratory yielded resistant, early maturing, and erect bunch Valencia mutants (viz. 1, 2, 8, 26, 39, 59 and 83)¹⁴. On subsequent mutagenesis with EMS, mutant-1 (VL 1) yielded secondary mutants (28-2, 45 and 110), which showed a high level of resistance with more desirable attributes¹⁵.

In the present study, 18 induced mutants were evaluated for foliar diseases reaction, productivity, and pod and kernel features along with DER and VL 1 parents and susceptible (JL 24) and resistant (PI 259747 and GBFDS 272) checks under both fungicide protected (Pr) and unprotected (UPr) diseased conditions. The experiment was conducted during the 1995 rainy season in a split plot design with two replications. The main plots consisted of two treatments, viz. (i) As a fungicidal treatment carbendazim (@0.05%), tridemorph (@0.05%) were sprayed to control leafspots and rust respectively at 60, 75 and 90 days after sowing. (ii) As a no fungicide

check treatment water was sprayed at the rate of 500 l/ha. The sub-plots comprised of 23 genotypes. Each genotype, except DER, was grown in a 2 m row with a spacing of 30 cm between rows. The plant to plant distance within a row was 10 cm. In the case of DER line spacing was 60 × 15 cm owing to its procumbent habit. In each replication, all the observations were made on the five randomly selected plants. Each genotype was scored one week before harvest of the crop for leafspots and rust on a 1-9 scale¹⁶. The data collected on leaf area affected due to leaf spots and rust and defoliation at five stages (70, 77, 84, 91 and 98 days after sowing) were used to compute total leaf area lost at different stages. From these data cumulative AUDPC (Area under disease progress curve), an overall indicator of disease resistance was calculated¹⁷. Mean productivity (MP) represented by the average yield under disease protected and non-protected conditions and stress susceptibility index (SSI)¹⁸ were used as criteria for assessing genotypes for diseases tolerance. The genotypes with higher MP and lower SSI were considered as productive and tolerant. After harvesting pods were washed, and dried, pod yield per plant (g) and shelling percentage were determined. Pod (beak, constriction and reticulation) and kernel (colour) features were recorded as per the descriptor published by IBPGR¹⁹.

As indicated by the field disease scores and cumulative AUDPC values, the incidence of leafspots and/or rust was significantly lower in the mutants than the susceptible

Figure 1. Disease development on parents (DER and VL 1) and selected mutants.

Figure 2. Pod and kernel features of susceptible cultivars (TMV 2 and JL 24), resistant germplasm (PI 259747 and GBFDS 272), resistant cultivars (ICGV 86590 and ICGV 87160) and selected mutants (28-2, 45 and 110).

check and parents (Table 1 and also Figure 1). The resistant Spanish mutants (28-2, 45 and 110) matured

early (103 days) compared to resistant checks. They also had desirable pod and kernel features, viz. smooth pods and tan kernels (Figure 2) and were comparable to susceptible check (JL 24) for yield and shelling outturn. They also recorded lower stress susceptibility index and higher mean productivity (Table 1). These mutants can be widely tested for their commercial release and/or profitably utilized in future breeding programmes.

Visual evidence of nitrate reductase exudation from plant roots

Praveen-Kumar and Uday Burman

Central Arid Zone Research Institute, Jodhpur 342 003, India

To prove the nitrate reductase exudation, roots of 22 plant species were kept in contact with filter sheet impregnated with *N*-(1-naphthyl)ethyl-diamine dihydrochloride, sulphanilamide and potassium nitrate. Nitrate reductase exudation was indicated by the appearance of root impressions in red colour. Nitrate reductase exudation was observed from the roots of 13 plant species even though roots of all species showed its activity.

NITRATE reductase (NR) catalyses the conversion of NO_3 to NO_2 (first step in denitrification process)^{1,2} and its high activity may lead to high N losses from soil^{3,4}. Like other soil enzymes, i.e. urease and phosphatase, microorganisms are known to be the source of its activity in soil². Plants may also effect the enzyme status in soil either by affecting the microbial population in rhizosphere or by directly contributing towards its pool as root exudates as in the case of urease and phosphatase^{5,6}. However, it is not known whether plant contributes directly towards NR activity in soils. Such an information may be useful in devising strategies for reducing NR activity in soil and controlling denitrification losses. Here, we describe a technique to find out whether grasses, crops and trees (Table 1) contribute directly towards NR activity in soil as root exudates.

A sheet of Whatman No. 1 filter paper was spread on a glass plate (60 × 45 cm) in a slanting position and clamped. Distilled water (100 ml) was gradually poured from the upper end of the sheet three to four times for washing. The sheet was then allowed to dry at room temperature. Subsequently, a mixture of *N*-(1 naphthyl) ethyl diamine dihydrochloride (NED, 500 ppm aqueous solution) and sulphanilamide (SA, 1% w/v aqueous solution), mixed in equal proportion was sprayed on the sheet through a chromatographic sprayer and was then dried in dark. Once again, the sheet was sprayed with potassium nitrate solution (100 ppm $\text{NO}_3\text{-N}$) and dried in dark. Next, the sheet was cut into 25 × 10 cm pieces and fixed on glass plate (20 × 7.5 cm) by folding and sticking the excess portion of the sheet on the reverse side of the plate with a cellophane tape.

Selected plants were irrigated and this facilitated up-rooting of these plants with their roots intact. Subsequently, roots were washed, first under flowing tap water and then with distilled water to remove adhering soil particles. Roots were mildly jerked to remove water droplets. Thereafter, roots were spread on to the glass plate and covered with a similar type of plate. Both

plates were held together by rubber bands and kept in dark for 4 h.

It was hypothesized that if exuded, NR will reduce NO_3 present on filter sheet to NO_2 . NO_2 would then diazotize with NED and SA and give the characteristic red colour⁷. Roots of *Cymopsis tetragonoloba* (var. Maru guar), *Vigna radiata* (var. S-8), *Vigna aconitifolia* (var. Maru moth), *Vigna unguiculata* (var. Pusa aseem), *Cicer arietinum* (var. BCG-9), *Zea mays* (var. Megha), *Triticum aestivum* (var. PBW 175), *Azadirachta indica*, *Albizia lebbek*, *Prosopis juliflora*, *Ficus religiosa*, *Simmondsia chinensis* and *Acacia ampliceps* left perfect impression in red colour on the filter paper (Figure 1). These impressions indicated the exudation of NR from roots.

However, theoretically the impressions would have also formed had NO_2 been exuded from roots. To explore this possibility roots were kept in contact with freshly prepared filter sheet sprayed only with NED and SA and not with KNO_3 . Absence of red impressions would confirm exudation of only NR by ruling out NO_2 exudation. However, we observed red-coloured root impressions in this case also. Though, exudation of NO_2 appears highly unlikely as it is toxic, highly unstable and is rapidly converted to NH_4 in plant⁸, but without discounting the possibility of its exudation, NR exudation cannot be proved. To test this, inhibition of root NR by sodium tungstate was tried⁹. The hypothesis was that

Table 1. Activities of nitrate reductase in roots of different plants

Species	Nitrate reductase ($\mu\text{g NO}_2\text{-N/g root}$ tissue/h)	Root impression
Crops		
<i>Vigna unguiculata</i>	1.00	Yes
<i>Cymopsis tetragonoloba</i>	7.71	Yes
<i>Vigna radiata</i>	2.48	Yes
<i>Vigna aconitifolia</i>	1.31	Yes
<i>Triticum aestivum</i>	5.80	Yes
<i>Zea mays</i>	9.90	Yes
<i>Cicer arietinum</i>	9.90	Yes
<i>Pennisetum glaucum</i>	3.13	No
<i>Sesamum indicum</i>	3.40	No
<i>Ricinus communis</i>	9.89	No
Trees		
<i>Albizia lebbek</i>	1.31	Yes
<i>Acacia ampliceps</i>	1.16	Yes
<i>Ficus religiosa</i>	0.87	Yes
<i>Azadirachta indica</i>	0.74	Yes
<i>Simmondsia chinensis</i>	0.44	Yes
<i>Prosopis juliflora</i>	0.54	Yes
<i>Acacia nilotica</i>	0.64	No
<i>Dichrostachys nutans</i>	0.55	No
<i>Colophospermum mopane</i>	0.65	No
<i>Acacia aneura</i>	0.58	No
Grasses		
<i>Lasiurus indicus</i>	9.45	No
<i>Cenchrus ciliaris</i>	10.39	No

Figure 1. Root impressions showing of nitrate reductase. '+' and '-' indicate exudation and no exudation of NR respectively.

appearance of red-coloured impressions even after NR inhibition would demonstrate NO_2 exudation while lack of it would show NR exudation. For this, plants were irrigated with $100 \mu\text{M}$ solution of sodium tungstate (Na_2WO_4) twelve hours before uprooting. Inhibition of root NR was confirmed by *in vivo* assay¹⁰. Roots irrigated with Na_2WO_4 did not produce red impressions on filter paper impregnated with (i) NED + SA only or (ii) NED + SA + NO_3 . Absence of coloured root impression in (ii) demonstrated complete inhibition of root NR by sodium tungstate because otherwise we would have observed at least a faint impression. These observations led us to conclude that NO_2 is not exuded. Therefore, our earlier observation (roots with uninhibited NR in contact with NED + SA only) of red root impressions on filter sheet suggests the formation of NO_2 on root surface. This is possible only if both NO_3 and NR are exuded. Exudation of NO_3 has also been reported in *Lolium perenne*¹¹. Further, Figure 1 suggests that NR is exuded from the entire root system rather than any specific site.

Root of *Pennisetum glaucum* (var. MH 179), *Sesamum indicum* (var. C 50), *Ricinus communis* (var. Aruna), *Colophospermum mopane*, *Acacia aneura*, *Dichrostachys nutans* and *Acacia nilotica* however, did not exude NR.

Estimation of NR in roots¹⁰ indicated its activity in

all plants (Table 1). However it was surprising that 7 crops out of 10, 6 trees out of 10 and none of the tested grasses showed its exudation. Plants studied belonged to different families but all plants of even one family did not exude NR. Therefore, it appears that exudation or lack of it was clearly a character of individual plant species.

Minerals and Metals in Ancient India, Vol. 1 **Archaeological Evidence**, by Arun Kumar Biswas (524 + xxix pp); Vol. 2 **Literary Evidence**, by Arun Kumar Biswas and Sulekha Biswas (259 + xvii pp). D. K. Print World (P) Ltd., New Delhi 110 015. 1996. Price: Rs. 3500 (US \$ 225) per set.

The writing of History involves a reconstruction of the past, through a process of research, making use of a variety of source materials. The sources of information may be in the form of written material (inscriptions, travellers' accounts, the literature of the period), material objects and structures (as handed down from the past, or as unearthed through the work of archaeologists), and even traditions (in the form of practices, folklore). The historical researcher draws upon all the available evidence, and exercises his/her reason and judgement to construct a coherent picture of the happenings in the past, consistent with the available evidence, and with the best of objectivity. It is a continuing process, where every painstaking and careful effort is valuable.

The construction of Indian history is beset with many problems. The civilization itself had its beginnings several millennia back, before the appearance of any literature or documentation. Through the ages, a good portion of the material achievements has been destroyed as a consequence of natural calamities and even more, the insensitive and brutal ravages by invaders and aggressions from outside. At the same time, it is so important to reconstruct and recapture the cultural and intellectual heritage of India's past, particularly from the point of view of the younger generation in the country, to give them a sense of legitimate pride and meaningful belonging to the motherland. Fresh discoveries by archaeologists, modern scientific techniques of dating and materials characterization, and the capabilities offered by the computer have all added new dimensions to the study of history.

One of the illustrious and earliest attempts to write a history of Indian science was by the late Acharya Prafulla Chandra Ray, who published his 'monumental work', *the History of Hindu Chemistry*, in two volumes during the period 1902 to 1908. This classic was later republished with additions, in

1956, under the title *History of Chemistry in Ancient and Medieval India* as edited by P. Ray (then Professor of Chemistry at the Indian Association for the Cultivation of Science, Calcutta). The enlarged edition has covered the period from pre-Harappan days (4th millennium BC) till the end of the Moghul period. It has included extensive references to the Sanskrit literature of the Vedic and Ayurvedic period, the literature of alchemy and also a section on metallurgy and working of metals.

There has been a natural and growing interest in research on the history of Indian science, since the time of our political independence (1947) and various initiatives have been taken by the Government and the science academies. Arising out of the recommendations from a symposium on the History of Sciences in South-East Asia, held in Delhi in 1950, the Indian National Science Academy set up a History of Science Board, which in 1964-65 became the National Commission for the Compilation of the History of Sciences in India. As a major step in stimulating academic and professional interest in this field, the commission had brought out in 1971, *A Concise History of Science in India* – a comprehensive volume encompassing the disciplines of astronomy, mathematics, medicine, chemistry and metallurgy, agriculture, botany and zoology – with contributions from specialists, and edited by D. M. Bose, S. N. Sen and B. V. Subbarayappa. This concise History surveyed the ground from pre-historic times up to the British period.

The present two-part monograph – a collaborative effort of Arun Kumar Biswas and Sulekha Biswas – has also been sponsored by the Indian National Science Academy, History of Sciences Division. The work that has been devoted to the subject of minerals and metals, their production and applications in ancient and medieval India, presents a detailed analysis of archaeological evidence and literary evidence (as available in Sanskrit), for the period up to 1400 AD.

The Biswas couple have brought their wide-ranging academic experience and scholarship to the formidable task they had set for themselves – of collection, collation, evaluation and construction of a vast body of historical material, to present substantial and valuable

conclusions. A. K. Biswas, who is presently Mahendralal Sircar Research Professor in History of Science, at the Asiatic Society, Calcutta, had been on the Faculty of IIT, Kanpur for over three decades (1963-95). His professional interests have been in the areas of applied chemistry, surface chemistry, mineral engineering and hydro-metallurgy. He has had a long-standing interest in archaeo-metallurgy and the history of science. His deep appreciation of India's cultural heritage has inspired him to author several books, including one on *Science in India*, and another on *Profiles in Indian Languages and Literatures*. Sulekha Biswas is a scholar in Sanskrit and has been a fellow-collaborator with Biswas, assisting him in the selection and interpretation of Sanskrit texts and treatises on science and religion.

Notwithstanding the overpowering volume and detail of material presented in the two volumes, what facilitates the reader and sustains the interest is the structured presentation. Volume 1 which presents the archaeological evidence is conveniently divided into 21 chapters. Both the preface to the volume and the introductory chapter outline the logic and methodology, and the research motivations. Following chapters two to seven, – dealing with the splendid variety of minerals, gem stones, metals, ornaments, tools and metal ware, and the associated technologies as unearthed at various excavation sites like Mehargarh (Baluchistan) (pre-Harappan), Mohenjo-Daro (Sindh, Pakistan), Harappa (Ravi basin), Chanhudaro (Sindh), Lothal (between Ahmedabad and Bhavanagar, India), and Ahar (near Udaipur, India) – chapters 8 and 9 are devoted to the Chalcolithic cultures of Peninsular India and Eastern India, and chapter 10 to a critical evaluation of copper technology in ancient India. Iron technology in ancient India is covered in chapter 12 and again in chapter 19 (the Delhi pillar, wootz steel and Damascening). There are individual chapters devoted to particular topics: Minerals and metals in the Mahabharata epic sites, in Taxila through the centuries, India's trade in minerals and metals, and mining in ancient India.

Arising out of his own analysis of all the source material, Biswas makes bold to express the firm views that there was

BOOK REVIEWS

a continuity of the civilization from the pre-Harappan to the post-Harappan era (there was no invasion from outside), and that both copper technology and iron technology were indigenous developments and not the result of any diffusion from other civilizations. He has asserted that he has been very objective in making these assessments and no chauvinistic sentiment has clouded his judgement.

One of the amazing achievements of ancient Indian metallurgy is the carbothermic reduction of roasted zinc blende (sphalerite) to distil zinc vapour and recover the condensed metal. A collaborative project among M/s Hindustan Zinc Ltd, the Department of Archaeology, Baroda University (K. T. M. Hegde) and the British Museum Research Laboratory (P. T. Craddock and colleagues) involving archaeological excavations in the Zawar region of Rajasthan, brought to light extensive debris of the ancient zinc smelting furnaces and retorts. Through techniques of ^{14}C dating, the activity has been placed in the first millennium BC. The primacy of India's contribution to zinc smelting is now well accepted. It was not till 1730 AD that a similar technology for zinc extraction was successfully attempted in the Western world (in England). Biswas, who had carried out investigations on the characterization of Zawar zinc retort residues, has dwelt at length on the scientific basis of the Indian process, in his chapter on 'Antiquity of zinc and brass in ancient India' (chapter 18).

Volume 2 is a search for and survey of references to minerals, metals, processes and related concepts in Vedic and Sanskrit literature up to fourteenth century AD. It is an eloquent illustration of the versatility of the Sanskrit language to develop an extensive vocabulary to distinguish various minerals and metals in relation to their appearance and properties, to develop scientific concepts, and to deal with the subtleties of materials technology. At the same time, the Biswas team has made the observation that the references to minerals and metals in the Sanskrit literature are surprisingly scanty and scattered, the exceptions being the cases of Panini's *Asthādhyāyī*, Kautilya's *Arthasāstra* and the *Rasasastra* texts.

As interesting examples of etymology, for cat's eye or beryl Panini uses

the description *Vaidūrya* (derived from the city of Vidura where the gem was cut). While *ayas* was used as a general name for metal, *Kālāyasa* or black metal referred to iron and *lohitāyasa* or red metal referred to copper. *Padārtha* (which literally meant the meaning of a word) was also adopted to mean a material or substance.

Arthasāstra is an important sourcebook on the economic importance attached to materials and metals in ancient India. While there has been some controversy on the date of the *Arthasāstra* – placing it between 4th century BC and third century AD – Biswas accepts the traditional view that it was the work of Kautilya (also known as Chānakya or Vishnugupta), in the time of Chandragupta Maurya whose reign commenced around 321 BC. Apart from giving details on metal processing, the *Arthasāstra* also defines the duties and responsibilities of the director of mines (*Ākarādhyaksha*) and the director of metals (*Lohādhyaksha*).

Volume 2 devotes a long chapter to gemmology literature (a millennium of *Ratnasāstra*) and a short chapter to non-gem minerals and metals in ancient Indian texts. Alchemy was pursued for a long time in India, perhaps even from the Ayurvedic period, but more prominently between fourth century AD till as late as the 14th century AD – but with greater emphasis on the use of minerals and herbs in health and medicine. Literature on Indian alchemy is voluminous, in the form of the *Rasasāstra* texts and is discussed in chapter 8 in this volume.

Rasaratnasamuccaya (compiled during the 14th century AD) has been described by the authors as 'a pinnacle in the Indian latro-chemistry'. It is interesting for the detailed descriptions related to mineral and metal processing. Extensive extracts referring to zinc extraction, brass and lead, and different kinds of iron are included in chapter 9, but the text is in Sanskrit, and the authors have not considered it necessary to provide English translations.

There is a closing chapter titled 'The future of the past' in volume 1, and a resume in Volume 2, where the authors have summarized the major conclusions from their work, and made suggestions for future work. Maps showing the sites of archaeological excavation, the chronological presentations of historical

information, the large number of tables giving the chemical analysis and other significant details of ancient objects, and the beautiful colour plates of jewelry, seals, implements, icons, metal work, stone sculpture, etc. all add great value to the presentation.

It is undisputed that Indian civilization – in the ancient and medieval periods – had touched great heights in the aesthetic application of minerals and metals, and in metallurgical accomplishments of a high order and pioneering quality. The authors have raised the familiar question why such a vibrant civilization did not maintain its leadership in the subsequent eras and did not proceed to develop modern science and large-scale technologies. (There are many aspects to this question as explained by B. M. Udgankar in his comprehensive article 'Scientific traditions and other traditions', *Curr. Sci.*, 1995, 69, 197–206.) The authors place particular emphasis on the stratification that had crept into society, where specific skills (like working with different metals: iron, zinc or gold) remained confined to particular castes and tribes, the intellectual class largely stayed aloof, and there was no effective cross-communication and discussion of experience.

The Biswas couple have produced a very impressive and valuable compendium of information, that should serve as a consolidated sourcebook for future historians and research workers.

Parasitic Infections of Domestic Animals: A Diagnostic Manual, Johannes Kaufmann. Birkhauser Verlag, Basel, P.B.No. 133, CH-4010. SFr 68. 1996. 423 pp. Price: DM 78.

Several textbooks on parasitology and parasitic infections of domestic animals are available. These mainly focus on the parasites grouped according to zoological classification; give detailed descriptions of morphology and life-cycle; and small notes on pathology, symptoms and control. Some of the books contain

separate host-wise chapters on postmortem diagnosis and control, again under zoological grouping. Methods of diagnosis wherever mentioned are insufficiently described to be of much value to the field laboratory staff.

A few manuals extant on the subject contain accounts of diagnostic techniques and requirements for biological products of the listed diseases. Some manuals produced by commercial houses contain excellent coloured photographs of the parasites and lesions, but do not provide sufficient information on diagnosis and control.

All these are of limited practical help to field veterinarians and staff of field laboratories, in the diagnosis of the parasites involved. Kaufmann has addressed the problem of reaching rapid and precise diagnosis of parasites involved.

Kaufmann is eminently suited to undertake this stupendous task as he has the experience of dealing with the subject both in the laboratory (he heads the Diagnostic Section of the Institute of Parasitology at University of Berne, Switzerland) and in the field as he worked in a field laboratory in Gambia in late 1980s. Besides the material collected by him then and used in the book, he has incorporated in it a lot of information gleaned from about 300 institutions and universities. He is the principal author and has tapped the expertise of some 74 scientists based in Africa and Europe who collaborated as contributors or advisers, in producing the book. The result is a unique, beautiful, practical and self-contained manual for rapid diagnosis and control of parasitic infections of domestic animals and poultry.

Though the book was primarily meant for use in Africa, it is of equal relevance elsewhere for rapid diagnosis of economically important parasitic infections occurring worldwide. A few gaps in the information of local importance can be easily filled in. The book is unique as it deals with the parasites host-wise, system-wise and organ-wise as a veterinarian encounters them in the field. As he collects material from sick animals, or performs postmortem examinations, the book keeps pace with him by providing information as to which parasite(s) to expect, and in establishing rapid specific diagnosis.

The first chapter is on METHODS

for identification of parasites by direct and indirect techniques. The former includes up-to-date methods for examination of faeces, blood, skin scrapings and tissues. Detailed descriptions of these methods have been given, viz. counting of ova and oocysts and their identification, recovery of lungworm larvae, culture and recovery of third stage larvae of nematodes and their identification, haematology including quick staining methods, viz. Diff-Quick®, QBC®, dark ground/phase contrast buffy coat, and skin scrapings.

As most parasites produce antibodies in blood these are detected by indirect immunological techniques – indirect fluorescent antibody test (IFAT) enzyme-linked immunoabsorbent assay (ELISA), immunoblotting (Western blot) and complement fixation test (CFT) adequate descriptions of which have been provided. These are specific antigen-antibody reactions. Within the limitations, the tests are useful in diagnosis of parasitic infections.

The above-noted techniques meet routine diagnostic requirements of field workers. But for epidemiological studies, molecular biological techniques for detection and identification of parasites using nucleic acid probes come in handy. The last section of the chapter describes the techniques based on DNA probes and PCR (polymerase chain reaction) or both: DNA-random amplification of polymorphic (RAPD)-PCR. These techniques being extremely sensitive and highly specific are finding increasing use in diagnostic parasitology.

The next six chapters describe parasites of cattle, sheep, horses and donkeys, dromedaries, swine and poultry, respectively. Each chapter is divided into 5 sections representing stages in which parasites may occur: in gut and faeces, blood and circulatory system, urinogenital system, internal organs, and on body surface, respectively. Under each stage, the parasites are described under protozoa, helminths and arthropods. Information on the parasites is presented under sub-heads: location, hosts, species description (morphology and life-cycle), geographic distribution, symptoms, significance, diagnosis, therapy and prophylaxis.

Rickettsiaceae (*Ehrlichia* spp., *Anaplasma* spp., *Cowdria ruminantium*, *Eperythrozoon* spp., and others) – a group of parasite-like pathogens often

seen in blood or tissue smears are also described for differential diagnosis.

The book is parasitology made-easy for field workers. It is a unique and 'well-conceived manual, intelligently and copiously illustrated'. It has some 300 colour and 400 black and white illustrations of parasites, their developmental stages, lesions, affected animals showing cardinal symptom(s), schematic diagnosis of life-cycles, keys, etc. The text is precise and concise. All this facilitates rapid diagnosis of parasitic infections of domestic animals under field conditions.

The book has been 'very reasonably' priced due to generous financial aid from three Swiss institutions (Ciba, Swiss Development Corporation and University of Berne). This brings the book within reach of veterinarians, meat inspectors, and teachers and students of veterinary parasitology who need it most.

B. S. GILL

110-A Aggar Nagar,
Ludhiana 141 001, India

The State of Food and Agriculture. Food and Agriculture Organization of the United Nations, Rome, Italy. 1995. 301 pages.

The 1995 State of Food and Agriculture Report of FAO has chosen agricultural trade as its special feature. The other sections are common to the different reports and provide an overview of the current agricultural situation in the world. The data provided by FAO constitute the most authentic information available to agricultural researchers and policy makers. The data are dealt with both from a global and a regional perspective. Of particular interest is the detailed analysis of the food security challenges facing India.

In the section dealing with India, emphasis has been placed on the 1990 economic crisis arising from the large foreign debt and repayment liability. The steps taken by Government since then have been summarized in a meaningful manner. However, the following developments after the introduction of

BOOK REVIEWS

the new Economic Policy in 1991 highlighted in the report merit careful consideration.

- The inward-looking, import substitution development strategy, which was aimed at rapid industrialization, shifted resources from tradable agriculture to industry by turning the terms of trade against agriculture.
- The overvaluation of the exchange rate subsidized imports and adversely affected all exports, especially agricultural exports.
- Most sector-specific policies at all stages of production, consumption and marketing of agricultural produce, worked against agriculture. For example, the price policy was in practice designed primarily to help the consumers. Farmers were generally given low administered prices in the name of helping the urban poor even when they had to pay higher prices for domestically produced inputs because of the protection given to local industry. In addition, a major proportion of the costs of the inefficient functioning of parastatal organizations, such as the Food Corporation of India, were borne by farmers.

The above problems continue to affect India's agricultural progress. The flow of credit to rural areas had gone down very steeply. It is only during the

last two years serious efforts have been initiated to reverse the drain of resources from the village to the town and city. Globalization of Indian agriculture offers both opportunities and challenges to policy makers. However, there is need for a coherent policy towards issues arising from globalization with particular reference to their impact on employment generation and rural livelihoods. Mass production technologies will kill the *production by masses approach*, which alone is relevant to our conditions of expanding population and shrinking per capita availability of land and water.

There is a detailed discussion on all aspects of agricultural trade. The report stresses that markets alone cannot ensure environmental quality and sustainable agricultural development. Private values often do not take account of social costs. The principles recommended for multilateral action under the World Trade Agreement include: non-discrimination, transparency, choice of measures that have minimum adverse environmental impact and commitment to the cause of eco-technologies. There is need to ensure a proper match between trade and environmental objectives.

As in the past years, the *State of Food and Agriculture* 1995, includes a computer diskette with time series data for about 150 countries.

In his foreword to the Report, Jacques Diouf, Director General of FAO has drawn attention to the World Food Summit scheduled to be held in November 1996 in Rome for the purpose of mobilizing concerted global action to

overcome problems of hunger and food insecurity. Diouf has pointed out that the deaths and sufferings associated with food insecurity are as unnecessary as they are intolerable. The end of hunger and malnutrition, far from being a utopian or poet's dream, is within the reach of our modern society's technology, resources and understanding of the underlying problems.

A similar conclusion was arrived at the Science Academies Summit on 'Uncommon Opportunities for a Food Secure World' held at Madras in July 1996. A summary of the conclusions of this Summit has already appeared in *Current Science* (1996, 71, 342-346). The Ten-Point Action Plan recommended by the Science Academies provides a blueprint for achieving food security at the level of each individual. There is no scientific, economic, environmental or political excuse for inaction in converting the opportunities opened up by modern science and technology for making endemic and poverty-induced hunger a problem of the past into field level accomplishment. The decision of the Government of Tamil Nadu to initiate a Hunger-Free Area Programme in the State is the first decisive step taken in our country to stress that ending hunger is an idea whose time has come.

INDIAN INSTITUTE OF CHEMICAL BIOLOGY

4, Raja S. C. Mullick Road
Calcutta 700 032

ADVERTISEMENT NO. 1/96

Applications are invited for the undermentioned posts for Indian Institute of Chemical Biology, Jadavpur, Calcutta 700 032.

1. SCIENTIST, GR. IV(3): 2 (two) posts

Rs 3700-125-4700-150-5000/- (Total emoluments Rs 11,005/- in the initial of the grade).

QUALIFICATION & JOB REQUIREMENTS

POST NO. (i) (PROTEIN ENGINEERING):

Applicants must have a Ph D degree and outstanding scientific records in the area of structure-function analysis of proteins and protein engineering. Expertise in peptide synthesis and sequencing is desirable. The applicants would be expected to develop independent and extramurally funded research programme.

POST NO. (ii) (HUMAN GENETICS):

Applicants must have a Ph D degree and outstanding scientific records in the area of human genetics/genetic epidemiology and sound knowledge of linkage and association analysis. The applicants would be expected to develop independent and extramurally funded research programme.

AGE LIMIT: 40 years as on 31 October 1996, relaxable for exceptionally meritorious candidates.

Further information can be had from the Director, Indian Institute of Chemical Biology, 4, Raja S. C. Mullick Road, Jadavpur, Calcutta 700 032.

INDIAN ACADEMY OF SCIENCES

Discussion Meeting on Instability and Transition in Fluid Flows

22-25 November 1996 – Orange County, Coorg District, Karnataka

This discussion meeting is intended to get together Indian scientists active in the area to discuss current research as well as possible future directions, and to encourage formulation of any joint projects that might be of interest to them. Speakers at the meeting will include Indian scientists pursuing research in stability and transition as well as some visitors from abroad, including Dr Jitesh Gajjar (University of Manchester), Prof. Michael Gaster (Queen Mary & Westfield College, London) and Prof. K. R. Sreenivasan (Yale University). A small number of places in the meeting will be available for students, university faculty and other scientists either working in the area or seriously intending to do so. If you are interested in attending the meeting, please send a copy of your bio-data with a brief statement of interest to

Prof. Roddam Narasimha
Centre for Atmospheric Sciences
Indian Institute of Science
Bangalore 560 012
(Fax: 080-334 1683, e-mail: roddam@cas.iisc.ernet.in).

Participants will be required to be present in Bangalore before the evening of 21 November 1996 and will be brought back to Bangalore on the evening of 25 November. Arrangements for transport to and accommodation at the venue of the meeting will be taken care of by the Indian Academy of Sciences.

Current Science

SUBMISSION IN ELECTRONIC FORM

Authors who have been informed of acceptance of their manuscripts may send the final version in electronic form on floppy diskette (3.5" preferred; IBM PC format only, *not* Macintosh). The text of the manuscript only should be supplied as a plain ASCII file with no formatting other than line and paragraph breaks. (Wordstar 5.5 or 7.0 and Microsoft Word for Windows 6.0 are acceptable, but ASCII is preferred.) A hard copy of the text, with all typesetting information (italics, bold, mathematical type, superscripts, subscripts, etc.) must accompany the electronic copy. Tables and figures must be supplied only as hard copy. The diskette must be labelled clearly with the following: manuscript number, file name, file information (ASCII or Wordstar, version number, etc.).

Text may also be transmitted as ASCII only by e-mail to currsci@ias.ernet.in.

We expect that electronic submission will result in quicker processing for publication.

INFORMATION FOR CONTRIBUTORS

GENERAL

All manuscripts should be addressed to the Editor, *Current Science*, P. B. No. 8001, C. V. Raman Avenue, Bangalore 560 080. Submission of an article will be held to imply that it has not been previously published and is not under consideration for publication elsewhere; and further, that if accepted, it will not be published elsewhere. *Three copies of contributions of all categories* are required, with a letter of transmittal giving (i) names and complete addresses of the authors and (ii) title of the contribution and the category in which it is submitted (see below).

Current Science is a multidisciplinary journal and therefore research and review papers of general significance that are written clearly and well organized will be given preference. All papers will be first assessed by a Reviewing Editor. Papers found unsuitable in terms of the overall requirements of the journal will be returned to the authors. The others will be sent for detailed review. *Both solicited and unsolicited material will be reviewed.* Authors of these papers will be notified of acceptance, rejection, or need for revision of the paper. Returned papers cannot be resubmitted.

Illustrations and other material to be reproduced from other publications must be properly credited; it is the authors' responsibility to obtain permission for reproduction (copies of letters of permission should be sent).

CATEGORIES OF MANUSCRIPT

General articles (not exceeding 5000 words) discuss current trends in research in a field that will be of interest to readers outside the field; interdisciplinary topics: science policy and administration; or some aspect of the application of science and technology to human needs or the impact of science and technology on society/ecosystems/life. They should include a summary not exceeding 100 words, introductory paragraph(s), brief subheads at appropriate places to point to what follows, illustrations that will help a general reader, and references.

Review articles (not exceeding 5000 words) are expected to survey and discuss recent developments in a field. They should be well focused and organized, and avoid a general, 'textbook' style.

Research articles (not exceeding 4000 words) should report research results of fairly major significance. They should include an abstract not exceeding 100 words, introductory paragraph(s), and brief subheads.

Research communications (not exceeding 2000 words) should contain important findings that are novel and of fairly broad interest. They should include a brief abstract and an introductory paragraph. Text should not be broken up under subheads.

Correspondence includes letters, not exceeding 500 words, that are of general interest to scientists. All letters cannot be published.

Scientific correspondence contains technical comments, including those on articles or communications published in *Current Science* within the previous six months. Letters may be reviewed and edited.

Research news articles are intended to inform nonspecialists about recently published advances or important findings discussed at a meeting. Authors should also send a copy of the paper(s) on which the article is based. Meeting reports should avoid merely listing brief accounts of topics discussed, and must convey to readers the significance of an important advance.

Research accounts articles are intended to be personalized reviews of research from the authors' own laboratory, based on a body of published work. The articles must provide appropriate background to the area in a concise introduction, which should also serve to place the author's work in proper perspective. Articles will normally

not exceed 8 to 10 printed pages.

Opinion articles present views on issues related to science and scientific activity. **Commentary** articles should contain expository notes on issues related to science and scientific activity.

Book reviews. Unsolicited reviews will also be considered. Reviews that merely 'list' brief descriptions of the contents cannot be published. Reviews should have 'context' and convey some information about the subject of the book.

Historical commentary and notes inform readers about interesting aspects of personalities or institutions of science or about watershed events in the history/development of science; most are expected to relate to India. Illustrations are welcome. Brief items will also be considered.

MANUSCRIPT PREPARATION

Manuscripts should be typed double-spaced on one side of white bond paper (21×28 cm). The pages should be numbered consecutively, starting with the title page and through the text, reference list, tables and figure legends. The title should be brief, specific and amenable to indexing. Not more than five **keywords** should be indicated separately; these should be chosen carefully and must not be phrases of several words. **Summary** and **abstract** should not have more than 100 words and should convey the main point of the paper, outline the results and conclusions, and explain the significance of the results.

Text. All papers should have a brief introduction. The text should be intelligible to readers in different disciplines and technical terms should be defined. Tables and figures should be referred to in numerical order. All **symbols** and **abbreviations** must be defined, and used only when absolutely necessary. Superscripts and subscripts and ambiguous characters should be clearly indicated. **Units of measure** should be metric or, preferably, SI. Methods should, as far as possible, be described briefly in appropriate table and figure legends.

Figures. In the case of line drawings one set of originals (without any lettering) is sufficient, with two copies containing lettering. In the case of photographs good prints are required with each copy of the manuscript; photocopies are not acceptable. Line drawings should be roughly twice the final printed size. The correct orientation should be indicated if not clear.

Photomicrographs and other photographs that require it must have a scale bar, which should be defined clearly in the legend. Primary data should be submitted as far as possible (e.g. actual photographs of electrophoretic gels rather than idealized diagrams).

References should be numbered in the order in which they appear, first through the text and then through table and figure legends. The following are examples of ways of writing references.

1. Mukundan, T. and Kishore, K., *Curr. Sci.*, 1991, 60, 355-362.
2. Constantine, G., in *Biology of Bats* (ed. Wimsatt, W. A.), Academic Press, New York, 1970, vol. 1, pp. 319-322.

Acknowledgements should be brief. Footnotes are not allowed except to identify the corresponding author if not the first.

Cover photographs. Good photographs (colour or black and white) that pertain to a submitted paper will be considered for use on the cover. Good *prints* and a legend should be submitted with the manuscript. In the case of a colour picture, a transparency will be required for printing if accepted.

PROOFS AND PUBLICATION

Two sets of galley proofs are sent to the corresponding author. A reprint order form accompanies the proofs.

The ever-ready pollen

Nature's oddities are often well beyond the best imagination of human mind. Some of these have indeed been the inspirations for a few of the most artistic and aesthetic creations by man. Often these oddities also pose clear challenges to his inquiring mind. Indeed as Stephen Jay Gould remarks, these oddities of Nature are the scientists' bread and butter. One such bizarre feature of the plant reproduction is reported in this issue by Sharma and Koul (page 598): the precocious germination of pollen grains in a species of *Trifolium*.

Normally pollen grain are released as well-protected units such that they could beat the odds of weather during their long journey, often hitch-hiking on the body of insects or birds or mammals from the anthers of a flower to the stigma of another flower of probably another plant. Obviously they are induced to germinate only by the uniquely suitable conditions prevailing on the target stigma. The conditions are so unique to each species that plant breeders have to frequently struggle to construct suitable growth media for germinating the pollen grains of different species.

However, occasionally in certain species the pollen grains are precociously germinated even before they are released from the anthers. Sharma and Koul report that in *Trifolium dubium* the pollen grains germinate well within the anther in all the anthers of all the flowers of all the spikes of all the plants they studied. They also found that in some situations the pollen tubes enter the stigma from the undehiscent anthers. They interpret it as a strategy to facilitate obligate self-pollination. This, however, is not consistent with their statement that the

'species practices high pollen competition'; one cannot visualize a severe level of pollen competition in a species that is obligate self-pollinated. There could be alternate explanation also: precocious germination of the pollen grains has also been interpreted as a strategy for gaining a head start in the severe competition among the pollen grains for the limited ovules in the ovary – a form of male-female competition in plants. This possibility is especially likely in *Trifolium dubium*, as there are only two ovules of which one at the base eventually aborts. Thus pollen grains would indeed be selected to be competitive to gain access to the ovule at the stigmatic end. But if this be true, Sharma and Koul might have to reevaluate the level of selfing in this species.

Flow process modelling

Whether we like it or not, we have to face up to the fact that the whole world has now come under the spell of the American ethos. One of the more disturbing aspects of this ethos is the notion that one has to choose between selling and being sold, with no other alternative being available. In this harsh climate of hard sell, so many tall claims are made that we become very wary of any claim at all. Take the case of computational fluid dynamics (CFD). It has been very common among some of its practitioners (the school of *hard* CFD?), to claim that with sufficient computing power available CFD has made or will make expensive wind tunnels and experimentation obsolete; that given enough computing power, any fluid dynamic problem can be

solved. To more rational and knowledgeable people, these claims have sounded like sheer madness. But it would be very foolish to let the hysteria put one off from correctly estimating the true potential of CFD. What is its real potential?

The reason that fluid dynamics is so hard is because nonlinearity is at its core, and as we all know, there are no general ways of dealing with nonlinear problems. As a consequence, even after more than a century of effort, we still have no real handle on the central issue, of immense practical importance, of turbulence, which Feynman considered the last unsolved problem of classical physics. Since theory could do little, one was forced to rely on experimental testing to solve the kind of fluid dynamical problems that needed to be solved off campus. What is not often noticed or recognized, is that such experiments and testing were often ingenious and clever, often drawing, with the help of theory, useful conclusions of a general nature from a small number of tests; but there was no glamour. In this frustrating situation, enter that panacea of modern times, the computer. Suddenly, it appeared that people who knew little mathematics or physics or fluid dynamics could suddenly 'solve' difficult fluid dynamic problems and even present the results in the most attractive colours. It appeared that turbulence was licked or was about to be so. *By Golly, it could even be done on a PC!* Or so the claims went. But what was the truth? Yes, it is true that many problems can now be solved, especially for complex geometries and flows, that could not have been dreamed of a decade ago. More important, there are flows of great industrial importance that can now be modelled at least approximately, but usefully, by CFD using inputs

from experiments and theory. But the problem of turbulence has not been licked. The shameful truth is that we still cannot compute, from first principles, how much power we would need to pump a given volumetric flow of liquid through a pipe if the flow rate is high enough!

Yet great successes have been achieved and are being achieved. There is a large body of hard facts to show that in the aerospace industry, CFD is now playing a crucial role in design and development. I would go so far as to say that some of the planes flying today, would not have been the commercial successes that they have become if it were not for the economies that intelligent use of CFD brought about. Less well known is the role that CFD can play in non-aerospace industries. It is for this reason, especially in the Indian context, that Ranade's article (page 602) is timely and appropriate. At a time when Indian industry is being exhorted to be competitive in order to survive, when it is often suggested that Indian companies are backward in not supporting inhouse R&D, that no attempts are being made to improve existing technologies, let alone develop new ones. Ranade's examples and suggestions show us an alternate, positive path. By the intelligent use of modelling, of grafting on to existing codes

incremental new details and ideas, it is possible to make suggestions and predictions that could have a significant impact on technology and hence on the economy. Ranade points out, and I believe correctly, that important inputs will have to come from basic research if this programme is to succeed; further that this effort, in order to be really successful would have to be a collaborative effort of scientists working in the universities, the national labs and in industry. There is a lot more than hype here. Let us hope that the vision projected here comes to pass and that CFD comes to play the useful and key role that it is really cut out for.

Designing molecular locks

Emil Fischer's 'lock and key' concept of molecular recognition is a century old. Spurred by the exquisite specificity of biological receptors (invariably macromolecules), chemists have in the last few years turned their attention to the design of molecular hosts which can recognize specific guests. The game is conceptually simple; design molecules which are most often hollow or concave and attempt to find guests which can then fit snugly into cavities stabilized by a variety of non-covalent interac-

tions. Specificity is then achieved by tuning cavity size and the nature of the binding interactions. While crown ethers, cryptands, cyclodextrins and cyclophane based systems were intensely investigated in the period between the mid 1960s and the late 1980s, attention has turned to diverse molecular scaffolds in recent times. A particularly versatile unit is the bile acid skeleton in which polar, functionalisable hydroxyl groups lie on one face of an amphiphilic molecule. Maitra (page 617) provides an elegant account of the use of bile acids in generating novel, artificial receptors and as auxiliaries in asymmetric organic synthesis. Laboratory design is still far from achieving the specificity and versatility of biological receptors. 'Molecular locks' are frequently the products of sophisticated design strategies. The interactions which bind the lock and key together are hard to control, except in the case of hydrogen bonds. The organic chemist is, however, not really bound by the limitations of biochemistry. The expectation is that imaginative design approaches will lead to novel molecules which will have diverse applications including use as molecular devices and sensors.

CORRESPONDENCE

Biotechnology

The views expressed on Biotechnology by A. S. Rao (*Curr. Sci.*, 1996, **70**, 955–956), P. Tauro and M. V. Nayudu (*Curr. Sci.*, 1996, **71**, 169–170) are timely, thought provoking and highly relevant to the progress of Biotechnology in our country in future years.

Biotechnology being a multidisciplinary subject, requires coordinated efforts and expertise of scientists with different backgrounds to be put together in order to achieve success. I had stated in my earlier article (*Curr. Sci.*, 1994, **66**, 137–140) that Biotechnology is an 'Olympics' involving the interplay of Biology, Chemistry, Physics, Mathematics and Engineering – particularly in developing technology out of microbial fermentations and manufacturing products on commercial scale. As such no one can be a complete 'Biotechnologist' with absolute mastery in all the disciplines, but one can form a part of the networking that is essential for achieving realistic goals in commercializing Biotechnology.

Biology is essentially the basic science on which biotechnology progress depends and in the case of Microbial Technology, Microbiology is the bedrock from which newer developments in Biotechnology would emerge. I believe and I have emphasized on several occasions that natural microbial biodiversity is the resource pool for discovering novel bioactive metabolites and there is an urgent need for exploring natural resources for novel microorganisms by innovative techniques and conserving them in well-organized germplasm banks. In combination with application of modern techniques of genetic engi-

neering and recombinant DNA technology including PCR, gene amplification, etc., unlimited potential for developing new technologies based on indigenous discoveries would emerge and make our research and technology competent and globally competitive.

The question to analyse and answer is how far are we presently prepared to accept this challenge in our country and are we doing the right things to meet the challenges in the 21st century – with the GATT, WTO and IPR coming into full swing when we have to play our role and achieve international competitiveness in Biotechnology.

In my opinion, the following are the most essential points on which focussed decisions need to be taken and implemented fast to achieve this competence and competitiveness.

We need to establish active schools of research at Universities and national institutes to explore, identify and conserve in pure culture germplasm banks of indigenous microbial strains which must represent biodiversity of the native microflora from the diverse ecosystems which our country is abundantly endowed with. Among microbes, expertise in the taxonomy, physiology and biochemistry of fungi and actinomycetes is either non-existent or will be vanishing as the older generation of microbiologists fade off and these areas need the proverbial 'shot in the arm' urgently. Research work and capability build up in the modern aspects of genetic engineering must keep pace with the positive developments in the developed world – for example the present use of filamentous fungal systems with their

capacity for protein hypersecretion as the preferred hosts for heterologous expression of genes (the 'Cassette Expression System') which we need to develop expertise in and apply to our future technologies in bioproduct manufacture.

We need to establish the infrastructure as well as the technical competence of germplasm banks conforming to international standards on a priority basis. Culture collection(s) so established must get recognition under the Budapest treaty to enable our biotechnologists in future years apply for international patents without the necessity of having to deposit our patent strains in other recognized culture collections abroad. National patent laws including the patentability of both naturally occurring and recombinant strains must be debated in depth and policy decisions quickly taken and speedily implemented.

In the light of some of the points discussed, human resource development for biotechnology becomes most vital for future progress. The culture of working in teams respecting one another's competence and expertise and putting the heads together to work out new problems and find innovative solutions through individual and collective creativity is most essential for Biotechnology as a science to blossom into world class technology in our country.

In situ pollen germination and selective ovular abortion in *Trifolium dubium* Sibth

Trifolium dubium Sibth, an exotic leguminous weed, practices a special pollination mechanism and non-random pattern of ovule abortion.

A procumbent annual herb, the plant bears lemon yellow flowers in compact hemispherical spikes. Each plant is profusely laden with flowers. Individual plants bear 41–54 corymbose heads. The plants range between 28 and 35% in their reproductive effort (as per dry biomass estimations).

Reproductive apparatus of the species comprises 10 diadelphous stamens (9+1), and a small, 640 µm long pistil. The stigma is papillate and wet. When receptive, it gets covered with copious,

lipoidal secretion which stains positive with Sudan-black B. Although small, the style is so curved as to bring the stigma close to anthers. The ovary is unilocular with two ovules.

The species is obligately self-pollinated. Every anther within a flower, every flower of a spike, every spike on a plant and every plant in a population practices *in vivo* pollen germination. Pollen grains (40–60 per anther, $\bar{X} = 49.14 \pm 1.08$) germinate inside anthers when the latter are close to stigma. Anthers dehisce following secretion of stigmatic exudates. The stigma surface gets covered with hundreds of germinating pollen grains

(Figure 1). Occasionally, anthers get detached from filaments, clog the stigma, and cover the stigmatic surface with germinating pollen grains and pollen tubes emanating therefrom. In some plants only pollen tubes come out of the anthers of intact stamens and enter the stigma. Pollen tubes traverse the style in bundles. Later, they grow along the ovary wall and fertilize both the campylotropous ovules, within the unilocular ovary. The species practices high pollen competition with about 250 pollen grains available for siring one ovule.

Following fertilization, both ovules register increase in size. The rate and extent of increase is always significantly greater in the ovule closer to stigma. The basal ovule always aborts. The site of collection of plants and their age notwithstanding, the pattern of ovule abortion is always the same. All mature pods are therefore, single seeded. Seed abortion is obviously non-random.

Discotic liquid crystals – Self-organizing molecular wires*

Neville Boden, Richard Bissell, Jonathan Clements and Bijan Movaghar

WHEN considering the possibility of commercially viable applications for discotic liquid crystals, it is worth noting that in the case of calamitic liquid crystals some 80 to 90 years elapsed between their discovery in 1888 and their first application in displays. Since discotic mesophases were only discovered in 1977 (ref. 1), it is not surprising that the first applications are yet to be realized.

Recent research has established that the individual molecular columns in discotic liquid crystals can act as molecular wires for the transport of charge^{2,3} or excitons^{4,5}. This unique property is set to give rise to commercial applications in fast high-resolution light scanning and xerography, and in environmental gas sensors in the immediate future, and, in the longer term, to hybrid computer chips which will enable us to communicate electronically with molecules.

The reasoning behind this optimistic vision of the prospects for discotics is discussed in the context of recent and current research.

Discotics as arrays of molecular wires

The high mobility of charge carriers along the individual molecular columns (wires) in discotic liquid crystals stems from their unique architecture. They are comprised of disordered stacks of disc-shaped molecules, such as the hexaalkoxytriphenylenes, arranged on a two-dimensional lattice (Figure 1). The separation between the aromatic cores is of the order of 3.5 Å, so that considerable overlap of π^* orbitals of adjacent aromatic rings occurs. This produces a quantum band structure along the columns with a band gap of 2–4 eV and a band width of approximately 0.1 eV. Charge carrier mobilities are in the range 10^{-2} to 10^{-5} cm² V⁻¹ s⁻¹ and typically at least 10^3 greater than the corresponding mobilities in the perpendicular direction. The perpendicular transport is fluctuation controlled or impurity assisted.

Long-range one-dimensional transport is generally not realistic in molecular solids due to the presence of structural defects, or deep traps. However, in discotic mesophases the liquid-like fluctuations in columnar or-

der, which take place on a time scale of less than 10^{-5} s, provide a 'self-repairing' mechanism.

This combination of properties is quite unique and opens up new opportunities for applications of liquid crystals.

Applications

Fast, high-resolution xerography

Recently it has been demonstrated that mobilities for photoinduced charge carriers in the columnar phases of pure, triphenylene-based discotic liquid crystals are of the order of 10^{-4} to 10^{-3} cm² V⁻¹ s⁻¹ (refs 3, 6) and are as high as 0.1 cm² V⁻¹ s⁻¹ in the highly-ordered helical phase of hexahexylthiotriphenylene⁷. This makes them suitable for use as the active charge transport layer in fast and high resolution xerographic and laser printing applications.

For the last 30 years, polymer organic photoconductors have been widely used as photoconductive media in the field of xerography and laser printing. The efficiency of photocopiers and laser printers is primarily due to the mobility of charge carriers in the photoconductive layer. Polyvinylcarbazole (PVK), for instance, exhibits a mobility in the range of 10^{-6} cm² V⁻¹ s⁻¹. However, this is too slow for application in fast laser printing and photocopying, and toxic inorganic compounds of selenium and tellurium are therefore used.

The surface field effect gas-sensor

The present generation of 'electronic noses' are based on an array of 16–32 individual gas sensors, each made from a conducting organic polymer which displays reversible changes in conductivity when exposed to polar volatile odours. Although the response is non-specific to individual odour molecules, a characteristic odour 'fingerprint' is obtained from the response of an array of sensors. However, a serious limitation of conducting polymers is the lack of response to non-polar molecules.

The surface of a discotic liquid crystal has a unique topology (Figure 2). Fluctuations in the lengths of the columns result in a 'conductive' surface layer. The

The authors are in the Centre for Self-Organizing Molecular Systems, The University of Leeds, Leeds LS2 9JT, UK.

Figure 1. A schematic view of both the D_h phase in discotic liquid crystals and a simplified electronic structure of an isolated molecule and the condensed state showing the band gap E_g .

Figure 2. A schematic illustration of a gas sensor exploiting the surface conductivity of the discotic liquid crystalline film.

Figure 3. A schematic view of a hybrid discotic liquid crystal/silicon field effect transistor. The molecular wires generate a 2-D band structure in the silicon inversion layer. The source-drain current is therefore sensitive to signals along the columns produced by sensing molecules absorbed in the film.

carrier mobility along the surface is fluctuation assisted and the tunnelling rates are exponentially dependent on the molecular core spacings. The core-core separation fluctuates with the surface and changes as soon as the surface is disturbed: i.e. locally melts, freezes, reorients, etc. The electrical conductivity of this surface layer is, therefore, very sensitive to the absorption of molecules. Discotic liquid crystals can therefore be used

Scheme 1. Synthesis of 2,3,6,7,10,11-hexaalkoxytriphenylenes.

Scheme 2. Synthesis of unsymmetrical triphenylene polymer precursor.

Scheme 3. Nitration of 2,3,6,7,10,11-hexahexyloxytriphenylene

as very sensitive gas sensors for both polar and non-polar molecules. The response has a physical origin and does not rely necessarily on charge transfer between the adsorbed molecule and the discotic aromatic core.

Communicating with molecules

The narrow electronic band structure, and the slow speed of response in discotic liquid crystals rule out many traditional semiconductor applications. We can, however, envisage applications for hybrid systems which combine the unique electronic properties of discotic liquid crystals with current silicon technology (Figure 3). Discotic liquid crystals form high-quality insulating films and could, therefore, replace the traditional oxide insulating gate in a field effect transistor. The novel feature now is that self-assembled molecular

Figure 4. Examples of smectic and discotic tetrafulvalene mesogens.

wires in the liquid crystal can address the 2-D electron gas in the inversion layer of the silicon. This coupling is strong enough to give rise to a hybrid band structure in the inversion layer with the effect of amplifying perturbations in the molecular wires via restrictions imposed on quantum pathways. In this way we can transform molecular signals arriving in the molecular wires into electronic signals in silicon chips. Once in the chip, molecular signals, in the form of local current changes, or channel switching events ('on-off'), can be processed in the usual way.

Developments in design and synthesis

In our work we have used mainly hexaalkoxytriphenylenes. They are stable to heat, light and redox processes and their chemistry is fairly accessible. We are now able to produce large quantities of these materials of high purity and at an economic price. Routes for synthesizing low molar mass discotics⁸ (Scheme 1), polymeric discotics⁹ (Scheme 2), and for introducing substituents into the triphenylene ring¹⁰ (Scheme 3), are now available. The latter enables the electrical properties and phase behaviour to be fine-tuned. Device applications of discotic liquid crystals require the development of materials which are liquid crystalline at room temperature and can be easily processed as polymers.

Smaller band gaps can be achieved by using porphyrin, phthalocyanine or larger delocalized aromatic cores. Tetrathiafulvalene (TTF) and its many derivatives are principally studied in the context of solid state organic metals and superconductors. Significantly, we have recently made derivatives of (TTF) which, depending on

minor modifications to the core structure shown in Figure 4, form either smectic A or columnar discotic phases. In the former phase type there is no evidence of π - π stacking between the TTF cores and hence no pronounced electronic band structure in the material. The discotic phase, however, possesses ordered columns of TTF molecules arranged on rectangular lattice. We are currently investigating the electrical properties of this remarkable material. Thus by intelligent design, it is possible to introduce exciting functionality into discotic phases with the prospect of new applications for liquid crystals.

Modelling of industrial flow processes: Opportunities for performance enhancement

V. V. Ranade

Detailed flow modelling of industrial processes offers new possibilities for performance enhancement and innovation in design of process equipment. In this review, we describe the overall methodology of industrial flow modelling. Some examples of applications of flow modelling are described to illustrate the methodology. Challenges and opportunities with reference to the Indian context are discussed.

ALMOST all the processes relevant to the manufacturing industry (chemical, petrochemical, fertilizer, metallurgical, power, cement, etc.) involve flow of fluids in some way or other. The innovation and competitive edge of any manufacturing industry, therefore, rests on how well these flow processes are designed and operated. If the underlying flow processes are adequately studied and controlled, there is always scope for performance enhancement and for evolving innovative design solutions. There are many instances in the past where innovative analysis and clever engineering of flow processes have realized substantial enhancements even in the so-called 'mature' technologies. One of the most striking examples of using knowledge of fluid dynamics to substantially enhance the performance of the reactor is the development of super-condensed mode of operation of fluidized bed polymerization reactors¹. With the right selection of nozzle design and nozzle locations, it is now possible to increase the capacity of such polymerization reactors by 50 to 100% (this means producing fifty thousand to one lakh tonnes per year of polyethylene more from the existing reactor!)

Performance enhancement of existing or new processes may be realized in a variety of ways such as producing more from existing equipment, producing better quality products, having lower energy consumption and more safety of operations with less pollution and so on. Realization of enhancement in any of the aspects mentioned above requires expertise from various fields ranging from chemistry and catalysis to reaction engineering, fluid dynamics, mixing and heat and mass transfer. For the given fixed chemistry/catalysts, the performance of industrial processes or equipment is a complex function of the underlying transport processes. These transport processes are in turn governed by the fluid dynamics and therefore on a variety of design and

operating parameters of process equipment. Specialized techniques and tools (of flow modelling) are therefore required to understand these complex flow processes.

Traditionally, experimental and semi-theoretical methods (like cold flow simulations or tracer studies) have been used to obtain the information about the fluid dynamics and mixing required for the process optimization. The information obtained from these methods is usually described in an overall/global parametric form. This practice conceals detailed local information about turbulence and mixing which may ultimately determine the process/equipment performance. With the emergence of high performance computers and advances in numerical techniques and algorithms, a relatively new approach to flow modelling of process equipment, based on computational fluid dynamics (CFD), is now available to engineers. This approach was mainly used by aerospace engineers so far. However, there is enormous potential of using it for many other manufacturing sectors including chemical, automobile, steel and cement. CFD deals with the solution of fluid dynamic equations on digital computers.

Computational modelling of industrial flow processes allows detailed analysis, at an earlier stage in the design cycle, for less money, with lower risk and in less time than experimental testing. Simulations have added advantage in that, diagnostic 'probing' of a computer simulation does not disturb the flow and usual operation! Various alternative configurations can be screened quickly using the validated CFD model. The detailed predicted flow field gives an insight into fluid behaviour and can sometimes give information which cannot be obtained from experiments. Therefore computational fluid dynamics (CFD) models are proving to be powerful aids in design and analysis of industrial flow processes. A critical review of CFD techniques and their potential and use for realizing performance enhancement will be useful at this stage. In this article, we discuss various aspects of modelling of industrial flow processes and its potential for enhancing performance of existing

V. V. Ranade is with the Industrial Flow Modelling Group, Chemical Engineering Division, National Chemical Laboratory, Pune 411 008, India.

and new process equipment. Some examples of applications of flow modelling from our own research and consulting experience are described to illustrate the methodology. Challenges and opportunities with reference to the Indian context are discussed.

Computational fluid dynamics (CFD) framework

Computational fluid dynamics framework here means a complete tool for predicting the flow characteristics of the desired equipment. Various aspects of CFD framework along with key references are shown in Box 1. Several reviews describing the details of these aspects have been published (for example, refs. 2, 3). Here, we discuss some of the major issues without describing the mathematical details of specific formulations.

Transport equations

The closeness of predictions of the CFD model with the real flow behaviour depends on how well the user has represented the underlying physics in the mathematical formulations. Most of the industrial flow processes relevant to the process engineers, are complex and cannot be represented rigorously. The user, therefore, must appreciate the implications of the assumptions on which the formulation of the transport equations is based. Here we restrict ourselves to discussing major issues in the formulation of transport equations relevant for turbulent, dispersed multiphase flows, which are often encountered in chemical processing equipment.

Turbulence is often employed in industrial equipment to enhance the rates of transport processes. Turbulence is a three-dimensional, time-dependent, nonlinear phenomenon. The instantaneous velocity field in a turbulent flow is described by the Navier–Stokes equations. However because of the existence of extremely wide range of space and time scales in turbulent flow, direct numerical

simulation of turbulent flows is possible only at relatively low Reynolds number and that too if the geometry is simple. For most engineering applications it is still necessary to use turbulence models along with time averaged Navier–Stokes equations. It must be realized that most of the available turbulence models obscure the actual physical processes like eddies, high vorticity regions, large structures which stretch and engulf and so on. However, the cautious application and interpretation of turbulence models have proved to be a valuable tool in engineering research and design, despite their physical deficiencies.

A turbulence model is a set of equations which express relations between the unknown terms appearing in the time averaged Navier–Stokes equations and the known quantities. Two equation turbulence models are the simplest ones that promise success for flows in which length scales cannot be prescribed empirically. The k - ϵ model is the most widely tested model for a variety of complex flows. Many modifications such as multiple scale k - ϵ models or extra terms to compensate the shortcomings of standard k - ϵ model have been developed. At present, the two-equation model forms the basis for most engineering simulations of complex flows. More advanced models which do not use the assumption of isotropic turbulent viscosity or the concept of turbulent viscosity itself have been developed (algebraic stress models and Reynolds stress models). Recently, renormalization group theory based (RNG) models of turbulence have been developed^{4,5}. In RNG based k - ϵ model, the values of model parameters are evaluated by the theory. Moreover, the modifications of standard k - ϵ model like low Reynolds number modification, extra term of rate of strain are given by the RNG theory. While these models have not yet been sufficiently tested for engineering flow simulations, the initial results are promising. Considering that the framework of the standard k - ϵ model can be readily extended to RNG based k - ϵ models, the standard k - ϵ model is recommended for initiating simulations of industrial flow processes.

Multiphase flows are encountered in a variety of important industrial processes. For example, dispersed two phase flows are involved in steel making, cement manufacturing, polyethylene and polyvinyl chloride manufacturing, the fertilizer industry and in thermal power stations. It is indeed necessary to adequately represent the underlying physics of interaction of multiple phases in their mathematical models. An extensive literature exists on the modelling of dispersed two phase systems (reviewed recently by Ranade³ and Sommerfeld⁶ among others). There are two principally different approaches to simulate dispersed two phase flows, namely, the Eulerian/Lagrangian and the Eulerian/Eulerian approach. When dispersed phase hold-up is not very small and dispersed phase is introduced through a distributed inlet

rather than a single nozzle, it is easier and more efficient to use Eulerian/Eulerian approach in which both the phases are treated as continua.

Interphase coupling terms make two phase flows fundamentally different from single phase flows. In addition to the standard drag force, there are several other forces like virtual mass force (arising from the inertia effect) and Basset force (due to the development of a boundary layer around a bubble) which appear in the interphase coupling terms. An order of magnitude analysis presented by Hunt *et al.*⁷ suggests that for large vessels ($D > 0.15$ m), where the square of the terminal rise velocity of bubble would be smaller than the product of the gravitational constant and characteristics length scale, the interphase coupling term will be dominated by the drag force term. Various correlations are available to estimate the value of drag coefficient appearing in the interphase drag force term⁸.

For turbulent two phase flows, one can either use a standard Reynolds averaging procedure or one can use a practice similar to 'Favre' averaging in compressible flows. The time averaging of interphase interaction terms is tedious and involves several correlations. Johansen⁹ has derived an approximation for the low dispersed phase holdup case with the particles following Stokes law considering all contributions (drag, virtual mass, history term and lift force). The assumption of gradient transport can be used to model the correlation between fluctuating velocity and dispersed phase holdup. The gradient transport is strictly valid only when the size of the energy containing eddies is much smaller than the distance over which dispersed phase hold-up varies significantly. It should be noted that in principle, the value of turbulent Schmidt number used in such gradient transport will depend on the size of dispersed phase particles and integral scale of turbulence. Turbulent eddies smaller than dispersed phase will not contribute to the dispersion of dispersed phase particles. At present, however, there is no systematic data or theory available to estimate the values of Schmidt number for turbulent, two phase flows. The user, therefore, has to exercise his/her discretion in setting these values and interpreting the results.

There are a variety of different flow processes, not covered in the above discussion. For simulation of granular flows, additional modelling of stress in moving assembly of solid particles, viscosity of solid phase and effective pressure for solid phase need to be incorporated in the flow model. There is also a large class of industrial flow processes which involves laminar flows of rheologically complex fluids like polymer melt, inks, paints and detergents. Several studies and reviews on modelling of different classes of flows (for example, Gidaspaw¹⁰ for granular flows and Crochet *et al.*¹¹ for non-Newtonian flows) are available. Without describing

these issues in detail, we now discuss some aspects of numerical solution of transport equations.

Numerical solutions of transport equations

Numerical solution of transport equations mainly comprises the discretization of the governing equations and the solution of the resulting algebraic equations. Discretization of the governing partial differential equations can be done using finite difference, finite volume or finite element frameworks. The finite element methods have not yet been rigorously tested for multiphase flows in three-dimensional domains. The memory requirements of these methods are also much larger than the corresponding finite volume methods. For equipment engineering applications, conservative form of the governing equations discretized using finite volume methods is most appropriate (at least at present) from the point of view of accuracy and economy of computational resources.

The accuracy of a numerical solution depends on how close by the discretized equations represent the original partial differential equations. The desire to use higher order approximations for discretization must be balanced against the limitations imposed by the complexity of the problem being solved, the availability of the computing resources, stability and convergence of the solution algorithm and capacity to tolerate unphysical over and undershoots. Among the various schemes, QUICK (or in modified form of SHARP¹²) and second order upwind differencing schemes¹³ look more attractive from the point of view of accuracy and ease of implementation. In complex multiphase flows, a hybrid or power law scheme¹⁴ is recommended at least at the beginning.

The selection of algorithm for solving the transport equations requires consideration of the coupling and signal propagation among the equations (and boundary conditions). It must be realized that there is no single best algorithm for all types of problems. One has to make a choice by evaluating convergence performance and ease of implementation. For multiphase flows, additional coupling between two phases through interphase forces need to be handled. Spalding¹⁵ has proposed an inter-phase slip algorithm (IPSA) for this. In most of the two phase flow cases, the choice of algorithm for pressure-velocity coupling is often dictated by transparency and ease of implementation. After selecting a suitable algorithm for treating velocity-pressure coupling, the task that remains is to devise a suitable method to solve finite difference equations to obtain values of variables at all grid nodes. Because of interconnectedness and non-linearity, the task must be performed by iterative methods. Various methods such as point by point iteration (Gauss-Siedel or successive over-relaxation), linear

Gauss–Siedel and strongly implicit procedure (SIP) have been used for solving single phase flows. Convergence of pressure correction equation is often a rate limiting step especially for single phase flows. The rate of convergence depends quite strongly on the choice of under-relaxation parameters. Various techniques including methods based on additive correction philosophy have been proposed to enhance the convergence rates. Recently multigrid techniques have been shown to be very efficient in enhancing the convergence rates. Existence of dispersed phase raises further hurdles in the convergence of the iteration procedure because of additional coupling through the interphase terms. Spalding¹⁵ has proposed partial elimination algorithm (PEA) to treat the interphase coupling efficiently. PEA involves manipulation of finite difference equations of the velocities of both the phases at the grid node to eliminate the velocities of the second phase from the finite difference equations.

Computer codes for CFD simulations

It is necessary to translate the already described solution procedure into computer codes to generate useful simulations of engineering equipment. A CFD code needs to be designed to give appropriate importance to general applicability, ease of use and economy of computations. Recently Cross *et al.*¹⁶ have discussed the trends in CFD software engineering which are useful for the few code developer.

Our group (iFMg) has developed a CFD code called *SPARE* (for *SP*Arge*d RE*actors) based on a partial elimination algorithm (PEA) and an inter-phase slip algorithm (IPSA, ref. 15) along with the SIMPLER algorithm¹⁴. The sets of discretized equations for each variable are solved iteratively by means of an ADI technique. The non-linearities in the phase momentum and turbulence equations are handled by standard under-relaxation techniques. The core subroutines and problem specification routines have been organized in separate groups. The major routines are designed in such a way as to enable the user to construct various algorithms by modifying just one program. All the empirical information and boundary conditions can be specified through a single routine¹⁷. The performance of *SPARE* has been extensively tested both qualitatively as well as quantitatively³.

Instead of expanding the capabilities of an in-house research purpose code to carry out complex engineering flow simulations, it might be more efficient to use a commercially available general purpose CFD code. The development of a suitable mathematical model can be done using an in-house CFD code. The validated model can then be incorporated within the commercially-available code to carry out real life simulations. A num-

ber of CFD codes are available commercially (recently reviewed and compared by Dombrowski *et al.*¹⁸), each with its own particular set of features. Most of these codes provide user-friendly facilities for modelling complex geometries and grid generation. The powerful postprocessing facilities developed by professional programmers also aid user interpretation of simulated results. It should be noted here that though a variety of ready-to-use commercial codes are available, the experience and insight gained through the use of in-house codes turns out to be very valuable. The most important feature of the CFD code from the point of view of industrial application is the ability to incorporate or extend the code via user-written modules. Because no matter how general the code is, it will be necessary to develop specific submodels to simulate specific processes. Many of these commercial codes provide the ability to incorporate user-defined physical property models, source terms and new numerical features.

Methodology of flow modelling

Steps in a typical flow modelling project are described in Box 2. The first step of any flow modelling project is to relate the fluid dynamics with the overall objectives of the project and its implications for the performance enhancement. The complexity of the flow modelling tool can then be decided to achieve the set objectives. It is also essential to understand and quantify various time and space scales and the geometric complexity of the

system. This will enable one to represent the problem at hand in a mathematical framework. After finalizing the objectives and mathematical model, the next step is to map this mathematical model onto the computer code. The mapping of flow model mainly consists of specifying the geometry of the equipment under study, generation of appropriate grids within the solution domain, setting terms in the transport equations included in the CFD code or supplying additional problem-specific submodels to the CFD code and specification of corresponding boundary conditions. Prior knowledge of the various scales and likely regions of steep gradients will help in generating a suitable grid for the problem at hand. While generating the grids, extremes of aspect ratios and skewness should be avoided. The grid orthogonality has relatively little impact on flow accuracy in general, provided the angle between grid lines is not too small.

Once the appropriate grid is generated, the user has to select/specify the necessary information about the properties of fluids like molecular viscosity, density, conductivity. The correct specification of boundary conditions on the edges/external surfaces of the solution domain is crucial for the correct mapping of the problem. Care must be taken to understand and eliminate the influence of the location of outflow and inflow boundaries on the predicted flow results. Wall functions are routinely used to provide boundary conditions near the wall for turbulent flows which avoid the necessity of using very fine grids near the walls. However, one must be careful about such usage especially when heat or mass transport from the wall is important or when the accuracy of calculation of forces exerted by fluid on walls is important.

Once the problem has been mapped onto the CFD code, a user is interested in knowing details of simulated results. However, it is extremely important to understand the sensitivity of the predicted results to a variety of parameters like grid spacing, time step, boundary conditions and so on. This will normally involve some preliminary simulations to arrive at desired values of a variety of parameters involved in the simulations. It is often convenient to use grid sequencing techniques to solve complex problems. Normally, converged results can be obtained rapidly for the small number grids even with zero initial guess for all over the solution domain. These results can then be interpolated and used as initial guesses for the finer grids. It is also often desirable to increase the complexity of the problem in steps after starting with the most simplified situation. Underrelaxation factors for the different variables need to be employed appropriately to enhance the overall convergence rates. Patankar¹⁴ has listed many suggestions in this regard. The monitoring of convergence for each equation can also give clues about how to enhance the overall convergence rate of a CFD code.

Once the results are obtained on a sufficiently fine grid, it is necessary to formulate effective post-processing strategies to display these numerical solutions so that many aspects of the flow structure can be carefully studied. Appropriate validation exercise can then be carried out to verify whether the CFD model has captured the important flow characteristics of the problem at hand. The validated flow model can then be used to understand the various features of fluid dynamics and its relation to the process performance. The insight gained through such an exercise may lead to the evolution of better configurations or better operating protocols which will eventually lead to enhancements in process performance.

Flow modelling examples

Mixer design

Stirred mixers are among the most common process equipment in the chemical and allied industries. In such mixers, the contained fluids are circulated by the rotating impeller. The flow around the impeller interacts with stationary baffles and generates complex, three-dimensional, inherently unsteady flow. The fluid dynamics and therefore, the performance of the mixer depend on a variety of design and operating parameters such as size, number and shape of impeller blades, location of impeller(s), number of impellers, etc. Considering the

large parameter space, conventional design procedures rely on thumb rules and empirical correlations. New and innovative designs are often sidelined because of time and resource constraints on carrying out experimental studies. Flow modelling will prove to be an ideal tool to understand the fluid dynamics and performance of these mixers. The validated flow models can be used to screen the large parameter space to identify most promising configurations. The complex interactions of baffles, internals (like coils/spargers), shape of the vessel and impellers can be conveniently studied using the flow model.

We have developed a computational model, based on quasi-steady state approximation, to simulate flow generated by a variety of impellers in fully baffled stirred mixers^{19,20}. The vector plot of the predicted flow field generated by a downflow pitched blade turbine (PTD) is shown in Figure 1 for a typical r - z plane. This figure shows the well documented flow pattern of PTD. It should be noted that these results were obtained without using any empirical impeller boundary conditions. The model predictions also show satisfactory quantitative agreement with the experimental data (Figures 2 and 3) over the wide range of impeller Reynold number. The computations also revealed a wealth of details about the flow structure around the rotating impeller blades which are hard to obtain experimentally. The flow model adequately captures the influence of impeller location, blade width, blade angle, etc. on the generated flow and mixing. Other important details like interaction of baffles and rotating impellers, fluid forces on the impeller blades can be analysed using the flow model. The predicted flow results will therefore be useful for analysing and improving the blending, solids suspension, residence time distribution and scale-up performance of the mixers.

Enhancing selectivity of series-parallel reaction system in stirred reactor

Many high-value chemicals (pharmaceutical products) are manufactured in stirred semi-batch reactors, in which the limiting reactant is added continuously to maximize the yield of the desired product. If the chemical reactions are fast, the yield and selectivity is mainly a function of mixing²¹. A variety of design parameters such as feed pipe location, feed pipe, impeller type and location, etc. affect the overall performance of such reactors. A flow model including the reactive mixing will be a very effective tool to optimize these systems.

We have considered a series-parallel reaction scheme carried out in a semi-batch reactor (schematic diagram of the considered reactor set-up is shown in Figure 4 a). A model was developed to understand the interaction of turbulent mixing and fast chemical reactions²². This re-

active mixing model was integrated with the flow model of the stirred reactor (as described earlier). The overall model was successfully applied to predict the yield and selectivity patterns of series-parallel reaction schemes under a wide range of parameters. The comparison of computed results with experimental data is shown in Figures 4 and 5. The model was used to evaluate the influence of feed pipe locations, stirrer speeds, reactant concentrations, reactor size and feed time, etc. on reactor performance. The study resulted in identification of optimum feed pipe location and feed rate of limiting reactants.

Bubble column reactors

A bubble column reactor (in which reactant gas itself provides the required stirring and mixing) offers an attractive way to carry out gas-liquid reactions because of its simple construction and easy operation. However, because of their simple constructions, bubble column reactors also have an inherent limitation of having fewer

degrees of freedom available to control their performance characteristics. In bubble columns, local flow, turbulence and gas hold-up distribution are interrelated in a complex way with the operating and design variables. A detailed flow model therefore becomes a necessity to understand these complex interactions and to interpret the experimental results. One of the major disadvantages of bubble column reactors is the high degree of back-mixing prevailing in such reactors. Performance of these reactors can be substantially improved by appropriately tuning the degree of backmixing by employing suitable column internals like radial baffles. Flow models can be advantageously used to minimize the required experiments for identifying suitable internals and for confident scale-up with these internals.

We have developed²³ computational models to make quantitative predictions of turbulent fluid dynamics of bubble column reactors operated in a heterogeneous regime. Two submodels are proposed to account for the influence of bubble wakes and column walls on the motion of bubbles. Model predictions show satisfactory agreement with the published experimental data over the wide range of column diameter and superficial gas velocities. Figures 6 and 7 show the comparison of the predicted results with the experimental data obtained for bubble column of 0.29 m diameter for two different gas velocities. The influence of radial baffles on mixing in bubble columns was adequately represented by the computational model²⁴. Detailed three-dimensional predictions along with the submodel for the sparger will provide invaluable information for scale-up and fine tuning of large bubble column reactors.

Fixed bed reactors

Performance of fixed bed reactors crucially depends on the distribution of reactants. Deflection baffles are often employed to evenly distribute the feed vapours coming from the reactor inlet in the form of high velocity jets. A computational model was developed to optimize the design of deflection baffles for an industrial fixed bed reactor. Pressure losses can be accurately predicted. The reaction kinetics can be coupled with the flow model to predict the detailed temperature and concentration fields within the fixed bed reactors. Fixed bed reactors are also used in the radial flow mode for a variety of large scale processes (isomerization of *p*-xylene, ammonia synthesis, etc.). Fluid dynamics of radial flow fixed bed reactors (RFR) is very complex and involves abrupt changes in flow directions. Flow models can help to optimize the shroud and support screen design, to minimize the flow mal-distribution and to enhance the performance of the radial flow reactor. Such a study is recently reported by Ranade²⁵. The predicted flow field for three different conditions is shown in Figure 8. The corresponding ve-

Figure 6. Bubble columns (from ref. 23). Comparison of predicted axial velocities of gas and liquid phase and gas hold-up with experimental data. $D = 0.29$ m, $H = 4.5$ m, gas velocity = 0.02 m/s.

locity profiles at the outlet of the catalyst bed are shown in Figure 9. It can be seen that, unless support screens are appropriately redesigned, loading more catalyst in the reactor (by filling zones B and C) may not lead to the desired increase in the throughput of the reactor (because of the severe mal-distribution evident from the profile *b* of Figure 9). Detailed flow modelling and simulations are therefore necessary to realize the full potential of the available catalyst (and to develop better understanding and insight).

Figure 8. Radial Flow Reactor (RFR) (from ref. 25). Contour plots of stream function. Comparison of predicted flow field for three different configurations of RFR. *a*, Catalyst in zone A, top cover plate with shroud; *b*, Catalyst in zones A, B and C, no shroud, with screens same as in *a*; *c*, Catalyst in zones A, B and C, no shroud, with adjusted screen resistances.

The list of applications of flow modelling may be enlarged to encompass almost all types of process equipments. We have carried out flow modelling of jet mixers²⁶, flow meters²⁷, polymerization reactors, etc.

Industrial flow modelling: The Indian scenario

The opportunities and potential for enhancing performance of the existing assets of Indian process industries are truly enormous. Apart from improving the utility of existing assets, flow modelling tools offer a unique opportunity to bridge the gap between technology suppliers and technology buyers. The expertise built over the years of experimentation can now be developed within short span with substantially less resources by judiciously using flow modelling tools and expertise. Successful realization of these potential improvements

depends on several factors. Two of the most crucial factors are availability of flow modelling expertise to solve practical problems and willingness and commitment of Indian industries to upgrade their technologies by investing in indigenous flow modelling research.

Basic flow modelling requires expertise in fluid mechanics and numerical techniques. However successful modelling of industrial flow processes requires much more knowledge and expertise than just these two fields. More often than not, industrial flow problems cannot be modelled rigorously. Broad-based chemical and process engineering expertise along with the knowledge pool on different fields ranging from estimation of physical properties, rheology to kinetics and catalysis is therefore essential. New approaches of flow modelling need to be developed to make the complex industrial problems tractable without jeopardizing the objectives. We have made a small beginning at National Chemical Laboratory (NCL) by initiating an 'industrial flow modelling

Figure 9. Radial Flow Reactor (from ref. 25). Profiles of radial velocity at the bed outlet.

group (iFMg)¹. We have an advantage of availability of a large chemical and process engineering knowledge pool at NCL. We are working on a variety of performance enhancement projects sponsored by Indian as well as multinational companies from abroad.

It is, however, essential to form a critical mass of industrial flow modellers (from research laboratories and industries) in order to derive the maximum benefits. Many industries in India have purchased commercial flow modelling codes. However, as far as we know, the use of these codes to solve real life industrial problems is very limited. In order to increase the level of confidence in the flow modelling approach, it is necessary to have more interaction between flow modellers and engineers working on practical problems. It may be necessary to form CFD user groups or to organize workshops to facilitate such interaction. (In October 1995, we had carried out one such workshop, along with the applications group of C-DAC, on industrial flow modelling.) This will help us to address the crucial question of availability of the required flow modelling expertise.

The other key factor of willingness of Indian industries to invest in flow modelling research also needs to be discussed here. Complex industrial flow problems cannot be solved in a few days. In the initial stages, it is indeed necessary to painstakingly build the required expertise to solve industrial flow problems either with indigenous or commercial CFD codes. Indian industry should, therefore, be willing to invest funds to develop

such an expertise and computing facilities for realizing the potential performance enhancements. Considering the costs involved (of manpower, hardware, software and other facilities), it may be worthwhile to formulate a consortium of industries (private as well as public sector) to fund such research on flow modelling of industrial processes.

It must be added here that first rate work on modelling of industrial processes can be sustained only if it is backed up by basic research in complex flows. It is necessary to identify short and long term goals for further research on both computational as well as physical aspects of industrial flow modelling. The most important areas of computational character in which further work is needed are:

- ways of conducting fine-grid computations cheaply;
- minimizing numerical diffusion without jeopardizing the robustness;
- preserving order and flexibility in CFD codes as the complexity of their physical content increases.

Further research on problems of physical character primarily concerns the development of better turbulence models and formulation of tractable approaches for simulating industrial flows involving inherently unsteady large scale flow structures. Recent advances in applying renormalization group (RNG) theory need to be explored further. The consortium mentioned earlier should therefore also invest part of their funds for such basic research. Such investments on flow modelling research will help us to bridge the gap which separates us and technologically advanced nations.

Concluding remarks

In this review, we have described the overall methodology for modelling of industrial flow processes. The opportunities and potential of using flow modelling techniques for realizing performance enhancement were discussed. The basic framework of computational fluid dynamics was described. Application of the suggested methodology was illustrated with the help of case studies.

Predictions of CFD models can go wrong for two main reasons (other than human error and machine malfunction): they may be based on physically incorrect mathematical representations of basic physical phenomena or upon numerically deficient representation (incorrect discretization, inadequate resolution, incomplete convergence and so on). The inadequacies of the later kind are easier to quantify. The bounds of numerical accuracy of the specific code can be obtained by comparing results with the analytical solution of some simple but representative problem. Villasenor and

GENERAL ARTICLES

Spalding²⁸ have presented 14 flow problems which can be used for the benchmarking exercise. Recently Haworth *et al.*²⁹ proposed a useful approach to error estimation and physical diagnostics in multidimensional CFD simulations. Only a carefully planned validation and benchmarking exercise can transform the CFD model and code into a useful design tool. Inadequacies of the mathematical model are almost always present because the physics of complex, turbulent and multiphase flows is not yet properly understood. It is the duty of flow modeller to identify those aspects of flow, which are crucial to process performance and represent it with adequate accuracy in the mathematical model.

Despite their limitations, computational fluid dynamic models have been shown to be capable of predicting detailed flow fields within industrial process equipment. CFD models can also be used to study aspects of flow which are not easily amenable to experiments (e.g. high temperature). This unique capability of a computational tool may have most impact on equipment engineering practice. Detailed flow modelling of industrial processes offers new possibilities for performance enhancement and innovation in the design of process equipments. With the emergence of cheap, high speed computing platforms and availability of the commercial CFD codes and support, flow modelling needs to be properly exploited by the process industry to maximize the performance of the various processes and process equipment.

Transforming growth factor beta (TGF- β) in bone remodelling

S. K. Maiti and G. R. Singh

Division of Surgery, Indian Veterinary Research Institute, Izatnagar 243 122, India

The current concepts of the role of transforming growth-factor beta (TGF- β) with regard to bone metabolism and fracture repair are reviewed. The sources, types, chemistry, cellular activity and the clinical applications of TGF- β have been discussed. In low concentrations, this growth factor has significant effects on bone remodelling. The use of TGF- β for practical therapeutic purpose remains an exciting challenge.

BONE differs from other tissues not only in physiochemical structure but also in its extraordinary capacity for growth, continuous internal remodelling and regeneration throughout postfetal life. Bone formation is a complex process regulated by diet, vitamins, hormones and growth factors¹. Growth factors are polypeptides that increase cell replication and have important effects on differentiated cell function. Growth factors were initially considered as systemic agents, but current evidence indicates that they act primarily as local regulators of cell growth². The transforming growth factor- β family of proteins, which comprises polypeptide growth factors that have diverse effects on the growth, differentiation, and function of cells, is receiving considerable attention for potential clinical applications and is likely of physiological and surgical significance.

Transforming growth factors

It is one of the most important growth-promoting osteoinductive substances, which have been identified at the site of fractures and other places. Transforming growth factors (TGFs) have been categorized into TGF- α (alpha) and TGF- β (beta). TGF- α has not been isolated from bone tissue and cannot be considered a local regulator of bone remodelling, although it is mitogenic for bone cells and stimulates bone resorption. TGF- α shared amino acid sequence, receptor-binding and functional activity with epidermal growth factors but had only weak transforming growth factors activity³. Furthermore, TGF- β by itself was completely ineffective, but together with TGF- α it potently induced growth of colonies of cell-line³.

TGF- β is a multifunctional growth factor that has been shown to mediate normal cellular physiology and tissue

embryogenesis and to participate in a variety of responses associated with inflammation and tissue repair⁴.

Transforming growth factor-beta

Sources

TGF- β was originally purified from human platelets⁵, human placenta⁶ and bovine kidney⁷. The largest source of TGF- β in the body is the extracellular matrix of bone and platelets may represent the second largest reservoir for the peptide⁸.

Chemistry and types

TGF- β is a highly stable molecule that consists of two identical chains, each containing 112 amino acids. TGF- β s are a family of polypeptide growth factors encoded by closely related genes. There are at least five TGF- β s: TGF- β_1 to TGF- β_5 . TGF- β_1 , β_2 and β_3 have been found in many species, including humans; β_4 has been found in chickens and β_5 has been found in amphibians⁹. All share 64–82% similarity in their amino acid sequence¹⁰. Human platelets contain a single form of TGF- β composed of two identical polypeptides constituting a dimer of relative molecular mass (Mr) 25,000 (ref. 11).

A very high level (more than 95%) of sequence homology for a single isoform of transforming growth factor- β among many species indicates that these five isoforms are not simply species-specific variants¹². All the five isoforms might be expressed within a single species, in which all or a subset of the transforming growth factors β s may be synthesized by particular tissue at specific stages of development, or, after appropriate stimulation. A number of biochemicals featured are shared by most of these closely-related proteins⁴. The mature TGF- β subunit contains two identical chains, each containing 112 amino-acids (except TGF- β_4) and 9 cysteine residues whose locations are conserved in all five isoforms¹³. The active proteins are approximately 25 kDa and are composed of two, usually identical, disulphide-linked subunits¹⁴. Physical characteristics of the mature polypeptide subunits of TGF- β s are listed in Table 1.

REVIEW ARTICLE

Table 1. Physical characteristics of the mature polypeptide subunits of TGF- β s¹⁵

Protein	Amino acids per subunit	Molecular weight (Mr) (Da)	Conserved cysteine
TGF- β_1	112	12,500	9
TGF- β_2	112	12,500	9
TGF- β_3	112	12,500	9
TGF- β_4	114	12,900	9
TGF- β_5	112	12,500	9

TGF- β is synthesized in precursor form that requires proteolytic processing. It is released from the cell in an inactive high molecular weight complex composed of the processed dimer in combination with amino terminal fragments of each of the two TGF- β monomeric precursors and a third uncharacterized molecule. The physiological mechanism by which TGF- β is released from the inactive complex is uncertain but may require specific enzyme activation^{16,17}.

Cellular activity

Transforming growth factor- β has a broad range of cellular activities, including the control of the proliferation and expression of the differentiated phenotype of several types of cells specific to the skeleton, among them the pluripotent undifferentiated mesenchymal cells (pericytes) for chondrocytes, osteoblasts and osteoclasts¹⁸. *In vivo* and *in vitro* studies have demonstrated the synthesis of TGF- β by chondrocytes and osteoblasts and their expression is increased in fracture callus and specifically regulates bone-associated activities that may be important for the initiation of repair of fracture¹⁹. Studies on the potential role of transforming growth factor β in soft tissue wound healing have shown that this molecule is released from degranulating platelets at the site of an injury, possibly to initiate a cascade of reparative events²⁰.

Histologically, TGF- β increases nuclear 34-thymidine labelling in the osteoblast precursor cell zone²¹. Studies with isolated bone cells show that TGF- β is a potent regulator of osteoblastic cell activity and on a molar basis TGF- β is one of the most effective mitogens so far described for osteoblast-enriched cultures from fetal bone^{22,23}.

Studies have also shown that TGF- β is the most potent chemotactic factor released from macrophages⁸. In addition to attracting macrophages to sites of injury, this peptide activates the synthesis of other growth factors and deactivates the production of hydrogen peroxide by macrophages, so that young tissues are not destroyed²⁴. Moreover, TGF- β has been shown to stimulate fibroblast-directed tissue repair by upregulating the production of extracellular matrix components, such as

collagen, fibronectin and proteoglycan, by upregulating the expression of cellular integrin receptors for extracellular matrix proteins; and by inhibiting the action of proteolytic enzymes that could destroy newly-formed osseous tissue¹⁶.

TGF- β produce pluripotent and biphasic changes in the biochemical activities of cells at particular stages of differentiation within the osteoblast lineage⁴. To date, most studies to evaluate the effectiveness of TGF- β s in bone are performed with the prototypical isoform of TGF- β_1 derived from blood platelets, but TGF- β_1 , β_2 , β_3 each have identical qualitative effect in osteoblast enriched cell cultures²².

All the three isoforms potently increase synthesis of bone DNA at low concentration but have reduced mitogenic activity at higher levels⁴. These isoforms also enhance synthesis of collagen and non-collagen protein and decrease activity of alkaline phosphate in osteoblast enriched cultures, but TGF- β_3 appears to be 3–10 times more potent than TGF- β_1 and β_2 (ref. 25). Similarly, the TGF- β s enhance replication of cells and production of bone matrix in cultures of intact bone *in vitro*. In most instances, the TGF- β s enhance synthesis of type-1 collagen and non-collagen protein in bone cells²⁶. The mitotic response to TGF- β is biphasic; low concentrations (below 100 rM) are stimulatory, whereas higher levels produce less of a stimulatory effect. At higher, less mitogenic concentrations, TGF- β alters expression of various activities associated with the osteoblast phenotype in different ways; under these conditions, TGF- β decreases alkaline phosphatase activity and similar to its effects in a number of other connective tissue systems, enhances the synthesis of type I collagen, the major organic element in the bone matrix^{22,27}. Furthermore, TGF- β_1 and β_2 enhance chemotaxis of osteoblasts²⁸, suggesting an additional role involving the recruitment of differentiated osteoblasts that may be necessary for new bone formation and fracture repair.

Recent studies in osteoblast-enriched cultures have demonstrated that TGF- β_1 increases synthesis of type 1 collagen polypeptide in the absence of mRNA transcription and decreases non-collagen in the bone matrix as a result of the action of TGF- β probably occurs by multiple transcriptional, post-transcriptional and post-translational events⁴. Some other activities of TGF- β s associated with the function of osteoblasts have also been examined. TGF- β_1 and β_2 increase the transcriptional and polypeptide levels of osteopontin, a protein in the bone matrix that is thought to be important in adhesiveness of bone cells²⁹. In osteosarcoma cultures, TGF- β enhances Type 1 collagen synthesis as well as the production of a variety of bone matrix-associated polypeptides such as osteonectin, osteopontin and alkaline phosphatase^{29–33}, but decreases osteocalcin synthesis³⁴. These findings indicate that TGF- β enhanced bone matrix accumulation and consequently the maintenance of

bone mass. In general, the stimulatory influence of TGF- β on bone matrix protein synthesis may be attributed to effect at the transcriptional level^{22,27,31}.

However, a direct relationship between the influence of TGF- β on type I collagen mRNA and polypeptide levels is not observed in isolated bone cells, suggesting that TGF- β has an additional supportive role in increasing bone matrix formation²². The protein in the bone matrix termed osteonectin, which may be involved in the deposition of type-I collagen and the transition between cartilage and bone, was increased by TGF- β_1 , in an *in vitro* model that was used to study repair of fracture³⁵.

Much less information is presently available regarding direct effects of the TGF- β s on osteoclasts or osteoclast precursors. Recently, however, biphasic effects on the development of osteoclast-like cells have been reported, in which low concentrations were stimulatory and higher concentrations were inhibitory. TGF- β_1 induces resorption of bone on synthesis of prostaglandin E₂ (ref. 36).

In fetal rat long bones, TGF- β decreases bone resorption³⁷, and this effect may be related to the ability of TGF- β to inhibit the formation of osteoclast-like cells *in vitro*³⁸. This difference may be a significant distinction in bone growth and development between the fetus and the new born; within very early stages of bone formation, matrix formation may be more important to the organism than bone remodelling. It is therefore suggested that TGF- β has an additional, indirect role in increasing or maintaining body mass³⁷.

With regard to formation of cartilage, the TGF- β s appear to increase differentiation of mesenchymal cells, production of proteoglycans, and replication of chondroblasts³⁹. In contrast, these agents usually decrease the proliferation and function of differentiated cells by more mature chondrocytes. For example, TGF- β s decrease the activity of alkaline phosphatases²⁷. The highest levels of TGF- β mRNA were associated with osteoblasts in developing bone, whereas TGF- β transcripts decreased in chondroblasts/chondrocytes with increased type II collagen expression⁴⁰.

In general, it seems that one important role for the TGF- β s is to include developmental transitions in cells that are involved in formation of endochondral bone at particular stages of differentiation. The predominant trend of these effects appears to be toward eventual *de novo* formation of bone⁴.

Clinical applications

The use of TGF- β s to enhance wound healing was first investigated by Mustoe *et al.*⁴¹, who applied this peptide directly to and immediately after the creation of linear incisions through the dorsal skin of rats. These investigators demonstrated a 220% increase in the maximum strength at the site of the wound after five days and an

acceleration in the rate of healing by at least three days compared with that in the control animals.

It is also suggested that this peptide molecule has the capacity to stimulate both intramembranous and endochondral formation of bone³⁵. Noda and Camilliere⁴² studied the effect of daily injection of 1 μ g of TGF- β directly into the periosteum of the parietal bones of neonatal rats. They showed that (i) the thickness of the treated parietal bones increases approximately twofold, (ii) this effect was localized to the site of the injection, (iii) no changes were observed in the contralateral bones or at distant skeletal sites.

Joyce *et al.*¹⁹ performed a similar study in the femora of newly-born rats and found that on daily injection of either TGF- β_1 or β_2 into the subperiosteal region of the femora, mesenchymal precursor cells in the periosteum were stimulated to proliferate and differentiate much the same as is observed during the embryological formation of bone and early fracture healing. After cessation of the injection, endochondral ossification also occurred and this resulted in the replacement of cartilage with bone. In addition, it was shown that injection of TGF- β_2 stimulated the synthesis of TGF- β_1 in chondrocytes and osteoblasts, suggesting autoregulation of this peptide^{9,19}.

It has been demonstrated that a single injection of 25–100 nanogram (ng) of recombinant human TGF- β_1 adjacent to the ear cartilage of rabbits stimulated the formation of bone after 21 days⁴³. In a subsequent investigation, they showed that exogenously applied recombinant human TGF- β stimulated the recruitment and proliferation of osteoblasts in critically-sized defects in the skull of rabbits. By assessing the temporal dynamics of the formation of bone in these defects, they demonstrated the potent osteoinductive activity of this peptide and its potential therapeutic applications for non-healing osseous defects⁴⁴.

The function of TGF- β , both *in vitro* and *in vivo*, can be highly variable. In some instances this growth factor inhibits cell growth and matrix synthesis, whereas in others it stimulates these processes. These different functions depend on the target cell, the presence or absence of other cytokines and the dose⁴⁵. In their study, Sumner *et al.*⁴⁶ suggested that the response to treatment with TGF- β was dose dependent, with the lower dose being more effective for enhancing bone ingrowth, whereas, high dose of TGF- β inhibited mineralization. Synthesis of osteocalcin, a calcium binding protein important in mineralization⁴⁷ is inhibited, possibly due to this growth factor.

A similar observation was also reported by Nielsen *et al.*⁴⁸, who injected TGF- β , 4 to 40 ng in every alternate day for 40 days after creation of tibial fractures in rats. Mechanical testing showed that TGF- β induced a dose-dependent increase of the callus at the site of the fracture.

REVIEW ARTICLE

Enhancement of bone ingrowth with TGF- β was also evaluated in the canine model⁴⁶. Sumner *et al.*⁴⁶ observed that treatment of an implant (titanium fibre metal-coated rod) with a combination of a hydroxyapatite-tricalcium phosphate coating and TGF- β may result in better bone ingrowth than that obtainable from grafting of the gap with autogenous cancellous bone. The amount of new bone formation in the three millimeter gaps adjacent to the treated implants was twice that in the gaps of the paired controls, regardless of the dose. The differences between the treated and control implants with regard to architecture of the new bone in the gap indicate that the mechanism of action of TGF- β_1 may include both proliferation of osteoprogenitor cells and production of matrix by committed osteoblasts⁴⁶.

Histological study with two *in vivo* models of osteogenesis have also demonstrated an increase in net formation of bone by TGF- β_1 and β_2 , when the agents were tested either by direct application to the tissue or by subcutaneous injection⁴².

Summary

The transforming growth factor- β s are polypeptide growth factors encoded by a family of closely-related genes that are expressed in numerous tissues and species. Bone was one of the first tissues in which locally-produced molecules with TGF- β like activity appeared to regulate normal cellular function, and the skeletal matrix probably comprises the largest reservoir of TGF- β s. *In vitro* and *in vivo* studies have indicated that TGF- β s can have either stimulatory or inhibitory effects on replication, lineage development, and differentiated phenotypic function in many types of skeletal tissue cells⁴.

The effect may be biphasic in the sense that low concentrations of TGF- β s stimulate proliferations of cells, whereas high concentrations inhibit proliferation. Even within the same cell lineage, opposite effects have been noted with different concentrations of TGF- β s, or with skeletal cells at different development stages⁴.

In foetal tissue, TGF- β stimulates differentiation of mesenchymal cells, proliferation of osteoblasts and synthesis of bone matrix, but it may also induce maturation into and through the osteoblast, chondrocytes and osteoclast lineages⁴.

Most evidence to date leads to the conclusion that the TGF- β s have an important role in the formation of bone and this has tremendous potential in therapeutic application for non-healing osseous defects and in different types of fracture healing.

Finally, continued *in vivo* and *in vitro* studies of these molecules are needed in order to evaluate their effective doses, appropriate duration of treatment, tissue specificity, receptor-binding, intracellular signalling and the

regulation of their activities by other local and systemic factors.

RESEARCH ACCOUNT

Bile acids in asymmetric synthesis and molecular recognition

Uday Maitra

Department of Organic Chemistry, Indian Institute of Science, Bangalore 560 012, India

This account summarizes the progress made in our laboratory towards the development of new uses of naturally occurring bile acids. Applications in Asymmetric Synthesis (intramolecular coupling, and intermolecular reactions) and Molecular Recognition are described with suitable examples.

NATURE is asymmetric and almost all chiral molecules present in nature are homochiral (i.e. they exist in only one of the two possible enantiomeric forms). Organic chemists have always been fascinated by the possibility of constructing natural products by total synthesis. This approach was very successful till the sixties for constructing racemic modifications of chiral natural products. The methodology for synthesizing only one (the naturally occurring form) enantiomer was not present in the organic chemists' 'toolbox' until the seventies. During the past two decades, however, asymmetric synthesis of a variety of molecules has been accomplished by chemists using an assortment of techniques. In most of these examples, the inherent chirality of natural products (such as terpenes, sugars, amino acids etc.) has played important role.

The 'lock and key' concept of Emil Fischer for explaining the specificity of enzymatic action has been known for a century. Deliberate attempts to mimic such biological processes in the laboratory with small organic molecules, however, started much later. Early work with cyclodextrins and subsequently with crown ethers were forerunner to a new area of research towards the design, synthesis, evaluation and applications of synthetic molecular receptors. Carefully designed studies on molecular receptors have provided new insight into molecular interactions. In addition, recent research has shown that many molecular receptors can be designed to have tailor-made properties and hence can be used as a variety of molecular devices including molecular sensors (see, for example, ref. 15).

1. Bile acids: their properties

Bile acids, secreted by the liver, are important metabolites of cholesterol (Figure 1). These compounds are sometimes found in the form of conjugates, specially with glycine and taurine. Most bile acids are

Figure 1. Representative examples of bile acids.

Figure 2. Schematic representation of the bile acid unit acting as a template for a coupling reaction.

characterized by two distinct faces, one being the hydrophobic top (β) face, while the other (α , bottom) face is functionalized with polar hydroxyl groups. In addition, the side chain terminates in a carboxylic acid or other polar functionality. These acids are believed to aid in fat metabolism *in vivo*¹.

A great deal of work has been carried out during the past three decades on the inclusion properties of bile acid crystals². The crystals of cholic and deoxycholic acids contain channels, wherein guest molecules such as low molecular weight ketones can be trapped.

We were intrigued by the orientation of the hydroxyl groups of varying reactivity arranged on the α -face of the bile acid backbone. Until the mid-eighties, there were no reports on the use of the bile acid moiety towards the design of chiral auxiliaries and molecular receptors. We set out to develop new chemistry of bile acids, and use them for asymmetric synthesis and for the design of novel molecular receptors. The progress we have made in the past six years is summarized in this account.

2. Bile acids in asymmetric synthesis

Since the late seventies, there has been considerable progress towards achieving asymmetric synthesis of bioactive molecules³. Numerous chiral auxiliaries and catalysts, such as those derived from amino acids, terpenes, sugars, etc. have been utilized. Surprisingly, readily available optically pure bile acids did not receive any attention at all.

We have used bile acids in two distinct ways to induce chirality in reaction products. One approach, described in §2.1, was explored for *intramolecular* coupling proc-

esses. The other strategy (§2.2) made use of cholic acid as a chiral auxiliary for *intermolecular* reaction.

2.1. Bile acids as templates for intramolecular coupling

7-Deoxycholic acid, shown in Figure 1, has two hydroxyl groups whose chemical reactivities are different. We decided to examine the possibility of attaching two reactive units to the two hydroxyl groups, and couple them to make one or more bonds. Since the bile acid moiety is chiral, it was anticipated that if the coupling generates one or more stereogenic centers, the product might be formed stereoselectively. This concept is shown schematically in Figure 2.

Our first attempt involved the coupling of two 4-substituted aniline fragments covalently attached to the chiral bile acid template. The reaction of 4-toluidine with formaldehyde and hydrochloric acid was examined more than a century ago by Julius Tröger⁴. The product from this reaction (Tröger's base 1), and its derivatives, have recently attracted a lot of attention for their rigid V-shaped structure which allows one to use this structural unit as a scaffold for the design of molecular receptors^{5,6}. We have demonstrated that with a suitable precursor (2 or 3), the template coupling does indeed occur efficiently⁷, with diastereoselectivity approaching 75% (3 producing an excess of 5a) and with good chemical yield (Figure 3). The stereochemistry of the newly-formed stereogenic centers in the major product was unambiguously determined by a combination of chemical and spectroscopic means, including the X-ray crystallographic analysis of a single crystal (compound 4a)^{8,9}.

More recently, we have shown that a similar strategy can also be employed for the asymmetric coupling of two 2-naphthol fragments (6 to 7) on the template (Figure 4)¹⁰. Chiral binaphthols are increasingly being used for carrying out a variety of catalytic asymmetric transformations, and further developmental work might lead to a *practical* template-based asymmetric synthesis of this versatile chiral unit.

2.2. Bile acids as chiral auxiliaries for intermolecular reactions

A slightly modified approach was adopted by us for using cholic acid as a chiral auxiliary for *intermolecular* reactions. We reasoned that we could make use of the 3-position of cholic acid for tethering a reactive unit, and the 7-hydroxyl group to position a flat aromatic surface for *shielding* one face of the reactive group. The target molecule (acrylate ester 8) was synthesized readily in 7 steps from cholic acid in good overall yield. We found that the Diels-Alder reaction of 8 with cyclopentadiene at low temperature in the presence of a Lewis acid oc-

Figure 3. Template synthesis of Tröger's base derivatives on a bile acid template.

Figure 4. Template synthesis of a binaphthol unit on a bile acid template.

curred readily to give the adduct in very high yield and with diastereoselectivity approaching 90% (**9a** in excess, Figure 5). That the naphthalene ring was indeed functioning as anticipated was confirmed when the 3-acrylate ester containing an acetate at C-7 (instead of the naphthalene as in **8**) failed to show any stereoselectivity under identical conditions. The Diels–Alder product was removed from the adduct by an iodolactonization procedure, regenerating the chiral auxiliary in 88% yield^{11,12}.

The same strategy has also been shown to be moderately effective for the stereoselective reduction of 2-ketoesters as well. The steroidal chiral auxiliary was attached this time to pyruvic and phenylglyoxalic acids to produce **10** and **11**, respectively, and low temperature reduction with lithium borohydride resulted in 70% stereoselectivity in the diastereomeric product mixture (**12** and **13** were major products, Figure 6). The absolute configurations were assigned by comparison of spectral

Figure 6. Asymmetric reduction of an α -ketoester on a steroidal auxiliary.

data with those of authentic samples¹³. Efforts to improve the diastereoselectivity are currently in progress in our laboratory.

3. Bile acids in molecular recognition

During the past two decades, there has been an explosive growth in research in the general area of 'Molecular Recognition' with synthetic receptors. A variety of molecular hosts have been constructed and their properties studied¹⁴. A number of potential applications of such designer molecules, including their use as

sensors¹⁵, can be envisaged. At the time our work was initiated, not much attention was focused on the use of bile acids for the design of molecular receptors. During the past five years, however, bile acids have been utilized by a number of groups for this purpose^{16–21}.

The unique arrangement of the three hydroxyl groups, along with the rigidity of the bile acid backbone, prompted us to construct novel molecular structures on the bile acid backbone capable of complexing small molecules or ions. The long term goal in this work is the development of molecular and ionic sensors, synthetic catalysts, novel organic materials, etc.

Figure 7. Molecular boxes on a deoxycholic acid scaffold.

3.1. Molecular boxes

Figure 8. A space-filling representation of the INSIGHT II minimized structure of molecular box 14. The aromatic unit attached to C-3 (left) is blocking a part of the cavity.

A simple approach adopted by us is schematically shown in Figure 7, which utilizes the two OH-handles provided by 7-deoxycholic acid. It occurred to us that by attaching two molecular 'arms' to these two handles, and finally bridging them with a third linker unit, we will be able to generate bile acid-based molecular boxes. Even though synthetically it was feasible, as we demonstrated by efficiently constructing compounds **14** and **15** (ref. 22), these boxes surprisingly did not seem to have enough room in the interior to encapsulate any 'guest' which we examined. Recent calculations²³ suggest that the two arms which were attached to the bile acid tend to adopt conformations in which one of the aromatic rings protrudes inside the cavity, thereby blocking the entry of any guest (Figure 8). Nevertheless, we believe that further work along these lines with other more rigid arms will lead to cavities capable of encapsulation of molecular guests.

Figure 9. Cation binding with 'Chola-crown'.

3.2. Chola-crown

A variation of the molecular box approach which we examined was to build a crown ether by linking two of the three hydroxyl groups of cholic acid by a single pentaethylene glycol unit. Since cholic acid has three hydroxyl groups, we believed that a 'Chola-crown' having another available functional group (OH) will be a potentially useful system for the construction of metal ion sensors. Relative reactivity of the hydroxyl groups, and geometric considerations suggested that Chola-crown **16** shown in Figure 9 might be produced in *one* step from cholic acid. Indeed, this was found to be the case²⁴. The low yield (ca. 10%) in the synthesis was acceptable since both reactants (cholic acid and pentaethyleneglycol ditosylate) are readily available. Alkali metal ion binding studies have shown that this molecule shows a slight preference for K^+ over other cations. We believe that this system will provide opportunities for the construction of potential alkali metal ion sensors.

3.3. Molecular tweezer

A variety of tweezer-like molecules have been known, which are characterized by the positioning of converging binding sites available within a single molecule. In synthetic molecular tweezers, the binding interactions commonly employed are π -stacking and H-bonding interactions. Some recently-synthesized molecular tweezers have shown high (ca. 10^5 M^{-1}) binding affinities

towards 9-alkylated adenines²⁵. We felt that the functionalization of the 3- and the 12-positions of bile acids can lead to a new class of molecular tweezers. Unlike the synthesis of molecular tweezers constructed else-

where, this approach is rather straightforward. Accordingly, we attached 1-pyrenoyl groups to these two positions of bile acids to construct a series of three steroidal molecular tweezers (17–19). Molecular modelling studies showed that a family of low energy conformations (gas phase) existed in which the two pyrene units could adopt approximately parallel orientations, thereby generating a deep cleft in between. Detailed NMR titration experiments showed that electron deficient aromatic compounds shown in Figure 10 bind moderately well to these hosts in chloroform²⁶.

The molecular structure of a single crystal of 19 has recently been solved²⁷. It is interesting to note that the conformation of the molecule is different from what we propose to be the 'binding conformation' in chloroform solution. The steroid molecules pack back to back, forming a bilayer, with the pyrene units arranged in a 'herringbone' fashion. One view of the crystal packing is shown in Figure 11.

More recently, we have immobilized the molecular tweezer to Merrified resin. Binding experiments by HPLC showed that the relative binding affinities of the immobilized host followed the pattern observed in solution. Further research in this area can possibly lead to the design of molecular filters.

Conclusions and future outlook

We have shown in this brief account how readily available bile acids can be utilized for a variety of purposes. We are currently exploring many other possibilities, such as the design of transition metal complexes using bile acid-based ligands, construction of bile acid-based

dendrimers, design of host libraries based on bile acids, etc. We believe that the outcome of some of this work may possibly lead to the development of molecules of considerable interest for practical applications.

ACKNOWLEDGEMENTS. I thank my co-workers, mentioned in the references, for their hard work and intellectual contributions without which the work described here would not have been possible. I thank DST and DBT for financial support of our work. SERC (IISc) and SIF (IISc) at Bangalore, and RSIC (CDRI) at Lucknow are thanked for computational facilities, for recording of high-field NMR spectra and mass spectra, respectively.

RESEARCH ARTICLE

Molecular band polarization in Comet Hyakutake C/1996 B2

U. C. Joshi, S. Ganesh, K. S. Baliyan and M. R. Deshpande

Physical Research Laboratory, Ahmedabad 380 009, India

IAU/IHW filter set is used to study the polarization in Comet Hyakutake in various molecular bands. The observations were taken on March 13.97 and March 18.88 UT dates using 1.2 m telescope at Mount Abu Observatory, India. The errors in the measurement of the percent polarization are very low ($<0.5\%$). The phase dependence of the polarization of C_2 and CN molecular emission bands due to resonance fluorescence is in good agreement with theory. However, the observed polarization in C_3 molecular band is found to be about 3% which is less than the predicted value. In the case of CN molecule, significant deviation is noticed in the direction of polarization vector from normal to the plane of scattering.

COMETARY polarimetry provides a very good technique to understand the properties of gas molecules and dust. The level of polarization is strongly correlated with the activity of nucleus and the presence of jets which exhibit increased polarization over the surrounding coma. The mechanisms for the cometary polarization are now known to be: (i) scattering of sunlight by the cometary particles, and (ii) the resonance fluorescence emission by the cometary molecules. However, the molecular

band polarization in visible spectral range has not been explored much, neither observationally nor theoretically. The theory of polarization of molecular bands was studied a long time ago by Mrozowski¹, though this work does not deal with molecular bands observed in comets. Since then there seems to be no theoretical work done on this subject. As far as observations are concerned, Ohman^{2,3} showed for the first time the presence of polarization in comets due to resonance fluorescence emission. Further works are by Blackwell and Willstrop⁴, Bappu *et al.*⁵, Kharitonov and Rebristy⁶, Le Borgne *et al.*⁷, Sen *et al.*⁸ and Joshi *et al.*⁹, where they have made measurements for comets P/Halley, Hartley-Good, and Austin in molecular bands, OH (3090 Å), CN (3871 Å), C_2 (5140 Å), etc. In most of the cases earlier to 1987 it is not clear whether continuum light was subtracted correctly from the measurements. In case of Comet P/Halley's recent apparition, IHW group provided similar IAU/IHW filter set to several groups and therefore it was possible to generate homogeneous data base for this comet. Subsequently, we made use of the same filter set in case of Comet Austin and now on Comet Hyakutake C/1996 B2, making it possible to compare the results on different comets.

Here we report the linear polarization measurements in some molecular bands in Comet Hyakutake C/1996 B2.

Observations and analysis

Observations were made with a photopolarimeter on the 1.2 m telescope at Gurushikhar (longitude = $72^{\circ}46'47.47''\text{E}$; latitude = $24^{\circ}39'8.84''\text{N}$; height = 1680 m above sea level) near Mount Abu, operated by Physical Research Laboratory, Ahmedabad. The PRL photopolarimeter fitted with IAU/IHW filter set was mounted at the Cassegrain plane. The polarimeter works on the principle of rapid modulation of incoming light by a fast rotating superachromatic (in $0.3\ \mu\text{m}$ to $1\ \mu\text{m}$ spectral region) Pancharatnam half wave plate¹⁰. The details of the polarimeter used are given elsewhere¹¹. The comet observations were made, with an aperture of 26.5 arcsec centered on the nucleus, on March 13.97 and March 18.88 UT decimal dates. The IAU/IHW filter set, used for observations, contains three continuum bands, 3650/80, 4845/65 and 6840/90 free from any cometary emission, and five molecular emission bands, CN (3871/50), C_3 (4060/70), CO^+ (4260/65), C_2 (5140/90) and H_2O^+ (7000/175) (all figures are in Angstrom, central wavelength/band pass). The solar type stars HD105590 and HD191854 were observed for photometric calibration. The entire photometric procedure including the measurement of flux values in different emission bands is described by Ganesh *et al.*¹² (Paper I). The details of the polarimetric analysis procedure are discussed by Joshi *et al.*¹³ (Paper II) who report the continuum polarization behaviour of the comet on the two dates.

In the emission bands, the observed flux is equal to the sum of the flux due to reflected solar continuum (F_C) and the flux due to the fluorescence emission from gas molecule (F_E). The contribution of emission polarization to the observed polarization can be found out with the help of Stokes parameters: $Q = FP \cos 2\theta$ and $U = FP \sin 2\theta$, where P is the degree of polarization, θ is position angle and F is the flux. The observed values of polarization P_{obs} and position angle θ_{obs} in emission bands are due to the mixing of emission light with continuum. Using Stokes parameters Q and U , one can estimate the emission polarization P_E and θ_E . We can write: $Q_{\text{obs}} = Q_E + Q_C$ and $U_{\text{obs}} = U_E + U_C$, where the subscript E and C stand for emission and continuum respectively. We write the final equations in the form,

$$P_{\text{obs}}F_{\text{obs}} \cos 2\theta_{\text{obs}} = P_E F_E \cos 2\theta_E + P_C F_C \cos 2\theta_C, \quad (1)$$

$$P_{\text{obs}}F_{\text{obs}} \sin 2\theta_{\text{obs}} = P_E F_E \sin 2\theta_E + P_C F_C \sin 2\theta_C, \quad (2)$$

where F_C and P_C are respectively the contribution of continuum flux in the emission band and the polarization due to this continuum.

The observed degrees of polarization in continuum and emission bands are listed in Table 1 and are plotted in Figure 1. The polarization due to continuum, P_C , in a particular emission band is estimated from Figure 1 by interpolation. The molecular band polarization P_E has been calculated using equations (1) and (2) and the values obtained are given in Table 2 along with various physical quantities needed in the calculation. The values of F_E and F_C are taken from Paper I. The value of F_{obs} is simply the sum of F_C and F_E . After inserting the known values of F_{obs} , F_C , F_E , P_{obs} , and P_C in equations (1) and (2), we get the values of $Q_E = P_E \cos 2\theta_E$ and $U_E = P_E \sin 2\theta_E$. The value of P_E is calculated from Q_E and U_E using the relation $P_E = \sqrt{(Q^2 + U^2)}$. The emission band polarization values thus obtained are listed in Table 2 and shown in Figure 2 in the form of bar diagram.

Results and discussion

The observed continuum polarization is very close to the theoretically-calculated polarization value taking grain characteristics similar to comet Halley (Paper II). In general, the polarization vector is expected to be normal to the scattering plane. However, the observed values (see Table 1) show a small deviation in the position angle in U-continuum and in CN band on March 13.97. The position angle in 3650 Å band on March 13.97 is 16 ± 2 degrees whereas in 4845 Å continuum band its value is 13 ± 1 degrees. Within the errors both the values can be taken as same. However, on March 13.97, θ deviates by about 4 degrees in 3650 Å band compared to the value in 4845 Å band, which is more than three sigma and therefore can be taken as real. This small deviation may be attributed to several factors, some of which are described in Paper II.

The polarization vector for the molecular bands is perpendicular to the scattering plane within the error of observation (c.f. Table 1). The position angle in the CN band shows a significant deviation from the normal to the scattering plane on March 13.97. However, the observed molecular band polarization is contaminated by the continuum. It would be more interesting to study the polarization behaviour of pure molecular emission which is listed in Table 2. Before we discuss the polarization behaviour of molecular bands, it is appropriate to look for the error in estimating P_E .

If we assume that emission and continuum bands have the polarization vector in the same direction (i.e. perpendicular to the scattering plane), then,

$$P_E F_E = P_{\text{obs}}(F_C + F_E) - P_C F_C. \quad (3)$$

From the observed data we notice that the above assumption is quite reasonable. We also notice that the errors in polarization measurements are extremely low (S/N ratio being more than 10); the worst case being the

*Continuum bands.

Figure 1. The observed continuum and molecular emission band polarizations plotted as a function of wavelength. The continuum points for March 13.97 and March 18.88 observations are joined by solid line and dotted line, respectively. The observed data are shown by filled circles and filled triangles for March 13.97 and 18.88 UT dates.

3650 Å band in which ϵ_p is ~0.5% (Table 1). The main source of error in the estimation of P_E is the error in flux measurements. The accuracy of flux measurement is estimated at a level of ~10%. Neglecting the error in polarization values, the expected error in molecular emission polarization can be written as

$$\delta P_E^2 = \left(\frac{\delta P_E}{\delta F_C} \right)^2 \delta F_C^2 + \left(\frac{\delta P_E}{\delta F_E} \right)^2 \delta F_E^2. \quad (4)$$

The ratio $r = F_C/F_E$ plays an important role in error estimation. If $r \gg 1$ (which is the case with CO⁺ and H₂O⁺) we can simply write,

Table 2. Values of the polarization for considered molecules in different wavebands

Waveband	March 13.97				
	M_C	F_C	F_E	P_C	P_E
3871 (CN)	10.5	9.23E-12	2.14E-11	6.38	2.48
4060 (C ₃)	9.92	1.43E-11	6.02E-12	6.17	2.02
4260 (CO ⁺)	9.77	7.18E-11	1.58E-12	6.06	48.3
5148 (C ₂)	8.88	1.95E-10	7.62E-11	5.79	2.47
7000 (H ₂ O ⁺)	7.86	2.56E-10	9.58E-12	6.41	20.04

Waveband	March 18.88				
	M_C	F_C	F_E	P_C	P_E
3871 (CN)	9.84	1.75E-11	3.32E-11	5.03	4.41
4060 (C ₃)	9.19	2.79E-11	1.18E-11	5.11	2.40
4260 (CO ⁺)	8.99	1.46E-10	3.04E-11	5.15	5.52
5140 (C ₂)	8.02	4.19E-10	6.89E-11	5.37	1.30
7000 (H ₂ O ⁺)	7.45	3.75E-10	1.71E-10	6.06	5.49

$$\delta P_E \sim r ((P_{\text{obs}} - P_C)/F_E) \delta F_E. \quad (5)$$

Using the values from Table 2 we see that r is rather large for the ionic molecules CO⁺ (~50) and H₂O⁺ (~30) on March 13.97, and therefore the emission band polarization for ions derived by this method has large errors. Therefore, the values of P_E and θ_E for CO⁺ and H₂O⁺ molecules on March 13.97, as listed in Table 2, may contain large errors and should be taken with caution. The CO⁺ shows very high polarization value (48%). In case of Comet Halley also, CO⁺ showed large polarization⁸, though in that case also the errors were large. However, for other molecules the value of r is about 1 and therefore δP_E is small.

The value of P_E for CN, C₂ and C₃ molecules is estimated to be less than 3% on March 13.97. However, on March 18.88 polarization values for CN, C₃ and C₂ molecules are 4.41, 2.40 and 1.30, respectively. Thus neutral CN molecule shows higher polarization (4.58%) than one would expect from theory as discussed later but the value of P_E for C₂ band comes out to be lower than expected. This could be due to the overestimation of continuum polarization flux. Since the error in the de-

Figure 2. Bar chart showing a comparison of emission band polarization for CN, C₃ and C₂ molecules on March 13.97 and March 18.88.

gree of polarization is very small ($\approx 0.24\%$), the major source of error seems to be overestimation of the continuum flux at 5140 \AA obtained using formulae given in IHW Circular 3 Feb. 1984 which are basically for solar type flux distributions. The energy distribution of the comet on March 18.88 is found to be reddened (Paper I) and also peaking near 4845 \AA compared to the solar analog. In the interpolation formulae to estimate continuum flux at 5140 \AA , more weight is given to continuum flux at 4845 \AA . Therefore, the flux gets overestimated in this procedure and the angle is also found to be significantly deviated from the normal to scattering plane. On the other hand, we estimated flux by linear interpolation between 4845 and 6850 \AA , which comes out to be $\approx 2.559 \times 10^{-10}$ in the 5140 \AA band. Using this value of flux, we obtain polarization value as 4.5% and angle θ as 7° , which are closer to theoretical predictions. The actual value for the molecular polarization is expected to lie between 1.5 and 4.5% .

The molecular band polarization $P(\alpha)$ observed at a particular sun-comet-earth phase angle α , is supposed to follow the following theoretical relation³,

$$P(\alpha) = \frac{P_{\max} \sin^2 \alpha}{(1 + P_{\max} \cos^2 \alpha)}, \quad (6)$$

where P_{\max} is the maximum polarization observed at a phase angle 90° . At the time of our observations, the phase angles were 36.9° and 38.1° respectively on March 18 and March 13. Theoretical calculations carried out by Ohman³ predicted a value of 7.7% for P_{\max} for CN and C₂ molecules. Putting this value of P_{\max} in the above relation, we get $P_\alpha \approx 2.7\%$ and 2.8% respectively for phase angles 36.9 and 38.1° for CN and C₂ molecules. Therefore, the observed values are in good agreement with the theoretically calculated values. The observed molecular band polarization values for C₃ are 2.02 and 2.40% on March 13.97 and 18.88, respectively which are less than theoretically predicted value of $\sim 6\%$ (P_{\max} taken as 19%). Similar values of polarization for C₃ band have been reported for Comet Halley and Comet Austin⁷⁻⁹.

Conclusions

In the present work we have reported molecular emission band polarization in Comet Hyakutake C/1996 B2. The observations were taken on two UT dates: March 13.97 and March 18.88 using IAU/IHW set of filters. The errors in the measurement of the percent polarization are very low ($<0.5\%$). The values of the polarization obtained in the present work and those predicted theoretically are in fairly good agreement for CN and C₂ molecules. However, in case of C₃ molecule the measured polarization values do not agree with the theoretically predicted value of $P_{\max} = 19\%$.

Organochlorine pesticides and preterm labour in human beings

Mamta Sharma* and Pradeep Bhatnagar

Environmental Toxicology Unit, Department of Zoology, University of Rajasthan, Jaipur 302 004, India

*Present address: National Research Centre on Camel, PB No. 7, Jorbeer, Bikaner 334 001, India

In this study, we compare organochlorine pesticides, viz. aldrin, isomers of HCH, metabolites of DDT and heptachlor in the circulating blood, cord blood and placenta of pregnant women undergoing full term normal delivery with those in premature labour. The data and the statistical outcome of the study show that the mean concentrations of organochlorine pesticides in maternal blood of cases of premature labour were not found to be significantly different from those of controls (full term normal delivery). Similar results were obtained from the residue levels of cord blood and placental tissue. An attempt has also been made to correlate the high concentration of chlorinated hydrocarbon pesticides with the initiation of premature labour on the basis of existing evidences.

THE widespread use of organochlorine compounds as insecticides during the past few decades has led to their ubiquitous presence in the environment. These compounds are highly lipid soluble and are resistant to environmental degradation.

In human beings these compounds are stored in fat-rich tissues and are resistant to metabolism. These substances are present in women and the foetus is exposed during *in utero* development by transplacental transfer. Exposure of the foetus is related to the maternal body

burden. Several studies have reported values of organochlorine pesticides in maternal blood and cord blood¹⁻⁸. Relatively high residue levels of organochlorine pesticides have been reported in women with premature delivery⁹⁻¹¹. Also DDT residue levels were higher in California sea lions which gave birth prematurely than in those with full term pups¹². Organochlorine pesticides may disturb the hormonal balance of pregnancy and perhaps precipitate labour. Some DDT analogs (p-p'-DDT and o-p'-DDT) are reported to have oestrogenic effect^{13,14}. It is also reported that oestrogen and progesterone metabolism is greatly enhanced by the hepatic microsomal xenobiotic metabolizing enzymes stimulated by chlorinated hydrocarbons¹¹. Thus, an elevated level could theoretically cause premature labour by decreasing the amount of available progesterone which maintains the homeostasis of pregnancy. The report further states that DDT and p-p'-DDE were found in all cases of abortion but no correlation was found between the accumulation of organochlorine pesticides and incidence of labour¹¹. In the present study aldrin, HCH and its isomers, metabolites of DDT and heptachlor in the maternal blood, cord blood and placenta of pregnant women undergoing full term normal delivery are compared with those in premature labour.

The women subjects, 19 to 34 years of age admitted into Mahila Chikitsalya, attached to Department of Obstetrics and Gynaecology, SMS Medical College, Jaipur were used in the present study. Eight women went into labour during 24-32 weeks of gestation and were considered as cases of premature birth. The remaining 22 women had normal full term labour and were used as controls. In general they had no history of any occupational or accidental exposure to pesticides. However, they were asked to fill up a questionnaire incorporating

factors relevant to pesticide residue accumulation such as social status, dietary habits, area of residence, weight, parity, age, habits of pesticides use, etc.

Five ml of maternal blood from each case was collected by venipuncture in preheparinized vials 4–8 hours before parturition. A fraction of placental tissue was collected in acetone-washed aluminium foil at the time of delivery. Umbilical cord blood was collected by squeezing the cord into preheparinized vials. All the samples were stored at -10°C in deep freeze and analysed within 48 hours of their storage.

Pesticides were extracted and separated from samples by liquid partition and column chromatography so they may be analysed by GLC and TLC procedures.

Pesticides from maternal blood/cord blood extracted by a method given by Bush and his coworkers in 1984 with little modifications¹⁵. To 2 ml of maternal blood or neonatal blood, methanol (5 ml) and 1:1 diethyl ether/hexane (8 ml) were added and the contents were shaken for 3 minutes by hand. Loss of solvent due to evaporation was assessed by weighing the tube before and after shaking. The contents were then centrifuged for 10 minutes at 3000 rpm. It was re-extracted by adding 8 ml 1:1 diethyl ether/hexane. Pooled solvent so obtained contains the lipophilic organochlorine pesticides.

The method adopted for the extraction of pesticides from the placental tissue is nearly the same as that described for the blood since the main contents of placenta

RESEARCH COMMUNICATIONS

are blood and blood capillaries. Two g of placental tissue was homogenized in pestle and mortar with a little sea sand¹⁵. All reagents and chemicals used were of HPLC and analytical grade and checked for any pesticide contamination.

Florosil column was used for the clean up of extracted samples. It was prepared essentially in the same way as described by Bush and his coworkers¹⁵.

A Hewlett Packard 5890 series II gas chromatograph equipped with ⁶³N foil electron capture detector (ECD) and coupled with an integrator, HP 3396 A was used for the analysis of samples. Purified nitrogen (IOLAR-I) was used as the carrier gas. A coiled glass column (1.43 m × 4 mm L × I.D.) was packed with solid support, chromosorb 100/120 mesh size along with the liquid phase 1.5% OV-17 + 1.95% OV-210. A known volume of the sample was injected into the column with the help of a 10 µl Hamilton syringe. The different peaks in the samples were identified by comparing their retention times with those of the standards. Quantitation of the samples was done by the data obtained from the integrator and were based on peak areas. Standards were obtained from Environmental Protection Agency (EPA), USA.

Detected pesticides were further confirmed by thin layer chromatography. Since, sensitivity range of TLC is much less than GLC, therefore extracted and cleaned samples after their analysis on GLC were concentrated prior to their use in TLC.

The calculations are based on biological statistics and values are expressed as mean ± standard error (S.E.). The difference in the pesticide residue level between different groups was analysed with the help of Student's *t* test. Significance between the residue levels of different groups was judged at 5% and 1% levels.

The concentration of organochlorine pesticides was estimated in the maternal blood, cord blood and placental tissue of each subject undergoing premature labour and normal delivery and the data and statistical outcome of the study are shown in Tables 1–3. The mean concentration of organochlorine pesticides in maternal blood of cases of premature labour was not found to be significantly different from that of controls (full term normal delivery). Similar results were obtained from the residue levels of cord blood and placental tissue.

The data and the statistical outcome of the study show that mean concentrations of organochlorine pesticides in maternal blood, cord blood and placental tissue of premature labour were not found to be significantly different from those of controls (full term normal delivery). Our findings are contradictory to the findings of O'Leary and his coworkers¹¹ from Florida in which mean and range of DDE in foetal whole blood from healthy white controls were 4.9 ppb (2 to 13 ppb) while the values in the premature group were 22.1 ppb (18.7 to 26.8 ppb). Similar findings were observed in the

Negro infants. The Negro premature group had a mean of 6.1 ppb and range of 3 to 12 ppb, while the Negro premature infant had a mean of 19.0 ppb and range 6.6 to 34.4 ppb. The above results suggested the involvement of high levels of DDE in the initiation of premature labour.

Our results do not coincide with the findings of Siddique¹⁶ in which he reported that relatively high levels of organochlorine pesticides, especially DDT and DDE in cases of premature labour as compared to full term normal labour in the specimen of maternal blood and placental tissue, could suggest the involvement of these pesticides in the termination of pregnancy.

Since, we could not find any differences in the organochlorine pesticide accumulation between preterm and full term cases, our findings suggest that there are some factors other than pesticides such as stress, high blood pressure, poor nutrition, excessive physical activity, smoking, infections, teenage pregnancy, anaemia and other medical conditions such as diabetic nephropathy and uterine anomalies which are responsible for the initiation of preterm labour.

Data is not stratified with age, parity, dietary habits, weight, social status, area of residence and pesticide use habits because there were only limited number of cases of premature labour.

Hence, from the present study it is not clear whether the organochlorine pesticides play any role in the initiation of preterm labour (Tables 1–3). Therefore, further studies are to be conducted in order to draw any conclusion about the antagonistic role of organochlorine pesticides in pregnancy.

Transfer factors of radionuclides ^{137}Cs and ^{65}Zn from soil to pearl millet and sorghum

P. Sachdev, M. S. Sachdev and D. L. Deb

Nuclear Research Laboratory, Indian Agricultural Research Institute, New Delhi 110 012, India

The soil to plant transfer factors (TF) of ^{137}Cs and ^{65}Zn were determined for two crops, sorghum and pearl millet, under irrigated conditions in greenhouse and under rainfed conditions in field. In the greenhouse experiment, the accumulation of ^{137}Cs was almost doubled when the soil contamination level was doubled. Under field conditions, ^{137}Cs concentration in both pearl millet and sorghum grains as well as straw was nearly four times more at 148 kBq kg⁻¹ level of soil contamination as compared to lower level of 74 kBq kg⁻¹ soil. The TF values for ^{65}Zn determined under greenhouse conditions for both the crops were nearly a hundred-fold higher as compared to ^{137}Cs .

AFTER the Chernobyl nuclear station accident in 1986, worldwide concern has grown to evaluate the dose of radiation which may affect man. The *Handbook of Parameter Values* for prediction of radionuclide transfer in the ecosystems published by the International Atomic Energy Agency¹ is based on data entirely for crops, animals and conditions found in temperate climate zones. Very few data are available for radionuclide transfer and uptake in tropical and subtropical ecosystems. In the published literature, data for the uptake of radionuclides from soil for tropical cereals, fruits, herbs, tea and root crops are few in numbers and primarily limited to Cs. Although more data are available for rice, due to the complicated nature of production and the number of varieties, the data are not consistent. Currently it is assumed that transfers to animal and man are similar to those in temperate environments. Whilst this

assumption is probably not unreasonable, it has never been validated.

Keeping these points in view, a study has been initiated to assess the transfer of ^{137}Cs and ^{65}Zn from soil artificially contaminated with these radionuclides to pearl millet and sorghum under rainfed conditions in field and under irrigated conditions in pot culture.

The field experiment was conducted in the Gamma Garden of the Indian Agricultural Research Institute research farm in 1994 kharif season. In field experiments in the main yield plots of 9 m² (3 m × 3 m), microplots of 1 m² (1 m × 1 m) were made and contaminated with 74 kBq kg⁻¹ soil (2 µCi kg⁻¹ soil) and 148 kBq kg⁻¹ soil (4 µCi kg⁻¹ soil) with ^{137}Cs . The entire upper 5 cm soil of the microplots (75-80 kg) was dug out and sprayed with the 500 ml solution of radionuclide containing the required amount of activity. The radionuclides were mixed thoroughly with the entire soil and the soil was then transferred back to the microplots and brought to 50% water saturation level to a depth of 20 cm. Radionuclides were allowed to equilibrate in soil for eight weeks and during this period the soil was kept between 35 and 50 per cent moisture saturation.

After equilibration period, pearl millet variety M-179 and sorghum variety PC-121 were grown with a row-to-row spacing of 40 cm and plant-to-plant spacing of 20 cm. The crops were fertilized with 80 kg N ha⁻¹ through urea applied in two splits, 40 kg P₂O₅ ha⁻¹ through single superphosphate and 40 kg K₂O ha⁻¹ through muriate of potash applied as basal.

As maturity, the plants were harvested and separated into grain and straw. In grain and straw samples from microplots, ^{137}Cs activity was measured using a 3" × 3" NaI (T1) flat type detector for ^{137}Cs , 0.661 MeV peak as per the procedures given in the IAEA Technical Report². The soil samples were also drawn from microplots to a depth of 20 cm. Though the upper 5 cm soil was contaminated with radionuclide, the soil samples were collected to a depth of 20 cm from six locations in each microplots with a Viehmeyer tube and pooled to a composite sample as per the procedure described in IAEA Technical Report². The soil samples were air dried, ground in a wooden pestle mortar and counted in a well type NaI (T1) detector (2.5" × 2.5"). The counting efficiency for ^{137}Cs was 0.881% for flat type detector and 11.82% for the well type detector.

A similar experiment was conducted under pot culture conditions in the same soil. Eight kg soil was taken in ceramic pots and contaminated with ^{137}Cs and ^{65}Zn at the rate of 148 kBq kg⁻¹ soil and 296 kBq kg⁻¹ soil, respectively. In equilibrated soils, four seeds of pearl millet or sorghum were sown and on germination the plants were thinned to two in each pot. Here the results on transfer factors of ^{137}Cs under both field and pot culture conditions and of ^{65}Zn in pot culture condition are presented. The data on soil to plant transfer factors of the

RESEARCH COMMUNICATIONS

radionuclides were computed as ratios of (Bq kg⁻¹ dry-matter or grain)/(Bq kg⁻¹ dry soil).

In the greenhouse experiment, the pearl millet and sorghum plants were harvested at maturity and separated into grain and straw. The grain and straw yields of pearl millet were 9.34 ± 1.75 and 22.46 ± 2.33 g/pot, respectively. The similar figures for sorghum were 11.27 ± 1.38 and 27.62 ± 3.45 g/pot, respectively. The data for ¹³⁷Cs transfer factors presented in Table 1, revealed that under greenhouse conditions at lower level of soil contamination with ¹³⁷Cs (148 kBq kg⁻¹ soil) it

Table 1. Transfer factor of ¹³⁷Cs in pearl millet and sorghum grain and straw under pot and field conditions

Soil contamination level (kBq kg ⁻¹)		Plant contamination (Bq kg ⁻¹)	Transfer factor (×10 ³)
Pearl millet (Pot experiment)			
145.8 ± 1.43	Grain	877 ± 188	6.01 ± 1.24

Table 2. Transfer factor of ⁶⁵Zn in pearl millet and sorghum grain and straw under pot culture conditions

Soil contamination level (kBq kg ⁻¹)		Plant contamination (kBq kg ⁻¹)	Transfer factor (×10 ¹)
Pearl millet			
145.5 ± 2.98	Grain	101.0 ± 22.3	6.96 ± 1.63
	Straw	56.8 ± 8.5	3.91 ± 0.61
293.6 ± 1.21	Grain	95.2 ± 15.3	3.24 ± 0.52
	Straw	87.3 ± 9.0	2.97 ± 0.30
Sorghum			
146.3 ± 0.33	Grain	63.5 ± 0.7	4.34 ± 0.05
	Straw	82.8 ± 2.2	5.66 ± 0.16
295.3 ± 0.44	Grain	117.7 ± 1.3	3.98 ± 0.03
	Straw	150.5 ± 10.3	5.10 ± 0.35

was 6.01×10^{-3} and 11.80×10^{-3} in pearl millet grain and straw respectively. At higher level of soil contamination (296 kBq kg⁻¹ soil), the transfer factors were much less both in grain and straw, the values being 4.49×10^{-3} and 6.38×10^{-3} , respectively. The transfer factor values for sorghum grain were 4.52×10^{-3} and 5.80×10^{-3} respectively, and for sorghum straw, 12.52×10^{-3} and 8.98×10^{-3} respectively at single or double levels of soil contamination with ¹³⁷Cs. Gerzabek *et al.*³ have reported from two field studies at two sites contaminated by Chernobyl fallout, the transfer factor values for potato tuber of 1.7×10^{-3} and for wheat straw 0.7×10^{-2} . McCee *et al.*⁴ calculated the plant soil concentration ratio, transfer factor and plant-plant ratios from fallout ¹³⁷Cs data of soil and plants and found that the greatest spread was associated with plant soil transfer factors. In absolute terms, however, the accumulation of ¹³⁷Cs in pearl millet and sorghum grains (Bq kg⁻¹ grain) almost doubled when the soil contamination level was doubled.

In the field experiment, the grain yields of pearl millet and sorghum were 24.14 ± 0.99 , and 22.44 ± 1.08 and straw yields were 73.67 ± 3.37 and 89.42 ± 4.24 q/ha, respectively. Under field conditions the transfer of ¹³⁷Cs from soil to pearl millet grain was 2.15×10^{-3} and 4.45×10^{-3} at lower level (74 kBq kg⁻¹ soil) and higher level (148 kBq kg⁻¹ soil) of ¹³⁷Cs contamination of soil, respectively. In sorghum grain the transfer factor of ¹³⁷Cs was 2.01×10^{-3} and 6.13×10^{-3} at lower and higher levels of soil contamination. Similar trend was observed in both pearl millet and sorghum straw. However in absolute figures (Bq kg⁻¹ dry matter), the ¹³⁷Cs concentration in both pearl millet and sorghum grain as well as straw was nearly four to six times more at higher level of soil contamination (148 kBq kg⁻¹ soil) compared to that at lower level of 74 kBq kg⁻¹ soil.

The transfer factor values of ⁶⁵Zn determined under greenhouse conditions and presented in Table 2, were found nearly a hundred fold higher than compared to ¹³⁷Cs for both pearl millet and sorghum. As an example, at lower level of soil contamination with ⁶⁵Zn (148 kBq kg⁻¹ soil or 4 µCi kg⁻¹ soil), it was 6.96×10^{-1} for pearl millet grain and 4.34×10^{-1} for sorghum grain respectively. The probable reason for higher transfer factor for ⁶⁵Zn observed is that, zinc being an essential plant nutrient is absorbed by plant roots in large amount and translocated to above ground portions, while ¹³⁷Cs enters the plant system along with potassium. A similar trend is also reported earlier for rice crop by D'Souza and Mistry⁵. However, the transfer factors for ¹³⁷Cs and ⁶⁵Zn reported here are lower than for rice crop under field capacity moisture regime, probably due to the differences in soil properties of tropical laterite, black and alluvial soils. Further, in absolute amounts, the ⁶⁵Zn concentration was higher in pearl millet grain than in straw portion, whereas in sorghum it was otherwise,

more in straw than in grain. It has been reported by Tulin *et al.*⁶ from a study in soils contaminated due to Chernobyl accident that the increasing levels of potassium fertilization reduce the absorption of ¹³⁷Cs from soil by oats. Similar observations were reported by Orlovius and Sattler⁷. Although in the present investigation the crop was fertilized with 40 kg K₂O ha⁻¹ and has illite as the dominating clay mineral, the contamination level did not show a decline in soil to plant transfer of ¹³⁷Cs in both pearl millet and sorghum.

The results reported here indicate that release of considerable amounts of radionuclides from nuclear facilities resulting in contamination of soils, may find their way into crops in the tropical regions and eventually into the food chain of man.

Stylar length variation in *Caesalpinia pulcherrima* (Caesalpinaceae) – Basic patterns

R. Lokesha, R. Vasudeva*, B. S. Sarala, P. Palakonda Reddy and S. N. Nayak

Department of Genetics and Plant Breeding, College of Agriculture, P. B. No. 24, Raichur 584 101, India

*Forestry Degree Programme, Sirsi 581 401, India

Caesalpinia pulcherrima (Caesalpinaceae) produces four categories of morphologically distinguishable flowers within the same inflorescence, viz. flowers with long, medium, short and rudimentary styles. The stylar length variation within an inflorescence was found to be discontinuous. The long-styled flowers were functionally hermaphroditic and are produced towards the basal region of inflorescences whereas medium, short and rudimentary styled flowers were essentially males and are produced towards top region. The adaptive significance of this variation has been discussed in the light of stochastic events of resource availability and plant-pollinator interaction.

STYLE lengths of flowers borne on different individuals vary notably among species exhibiting di and tri-stylous condition^{1,2}. Among andromonoecious species, male plants bear flowers with rudimentary styles while flowers of hermaphrodite plants possess normal styles^{3–5}. However, among angiosperms, perfect flowers borne on a plant or even within an inflorescence also exhibit subtle differences in floral morphology and/or function. For instance, flowers of *Callonia grandiflora* (Polemoniaceae) exhibit intra-individual differences with respect to style length, pollen tube growth rate and

morphology of stigmatic papillae⁶. Cruden and Hermann-Parker⁷ have shown that *Caesalpinia pulcherrima* produces two types of flowers within an inflorescence: hermaphroditic flowers with abundant nectar and normal style; male flowers with rudimentary style and poor nectar.

Of late, floral variations within an inflorescence have been viewed as a result of dynamic interaction among plants and their pollinators. In a recent study Ganeshiah *et al.*⁸ have shown that figs guard their flowers against depredation from agonid wasps by varying the stylar length among flowers within a synconium. Stochastic events of fruit set and availability of resources to developing young buds within an inflorescence may also determine the extent of variation in floral features. Hence intra-inflorescence variation in floral features may be more common in flowering plants and might also represent an important mechanism to increase pollination efficiency. However, studies documenting such variations are scanty.

We have attempted to assess variation in stylar length within inflorescences in *Caesalpinia pulcherrima* (Caesalpinaceae), its association with floral functioning and also the possible adaptive significance of such variations.

The experiment was undertaken at College of Agriculture, Raichur (16°15'N, 77°20'E; 389 m above MSL), Karnataka, India.

Caesalpinia pulcherrima (Caesalpinaceae) is a perennial woody shrub of Indo-Malayan origin⁹. Plants bear either bright red or yellow flowers throughout the year. The flowers exhibit psychophilic syndrome and hence are pollinated by butterflies and moths⁷. In *Caesalpinia*, the inflorescence is a compound raceme with primary, secondary, tertiary and quaternary inflorescences emerging from a common axis and blooming occurs in

RESEARCH COMMUNICATIONS

an acropetal succession (basal floral buds bloom first and proceed in upward direction). The flowers anthesis around 8.00 am and are retained on the inflorescence for well over two days. The older flowers change their colour to deeper shades. Generally fruit set is maximum in primary inflorescences followed by secondary inflorescences. In most cases tertiary and quaternary inflorescences fail to produce fruits.

During 1993 in each of the 18 plants found growing in the campus (nine with yellow and nine with red flowers), six randomly chosen inflorescences were tagged before blooming. The flowers were observed for the stylar character (length) throughout the blooming period and grouped into four categories, viz. long (if the style length was > 4 cm, extend above or at the same height of the anthers), medium (if the style length was between 3 and 4 cm), short (style length between 1 and 3 cm) and rudimentary (< 1 cm). The observations were repeated during 1994 for the same set of plants.

To assess the function of different styled flowers, they were separately pollinated artificially. Pollen derived from them was analysed for their size and percent fertility using acetocarmine stain test². The number of ovules per ovary was counted under a stereo-binocular dissection microscope.

Means were compared between groups by Student's *t* test, the frequency distribution by Kolmogorov Smirnov Test¹⁰.

Caesalpinia pulcherrima produces four morphologically distinguishable flowers varying in stylar length within an inflorescence (Table 1). Although the style length varies from 0.4 to 6.5 cm, flowers could be categorized into four groups viz. long styled (mean \pm SE = 5.67 ± 0.046 & 5.74 ± 0.048 for yellow and red morph respectively), medium (3.79 ± 0.110 ; 3.44 ± 0.143), short (2.06 ± 0.058 ; 2.09 ± 0.042) and rudimentary (0.65 ± 0.022 ; 0.67 ± 0.020) (Table 1). The frequency distribution of stylar length was multi-moded and departed statistically from the normal distribution (Table 1 and Figure 1; KS tests were significant with $P < 0.001$ between frequency distributions). The mean stylar length of each of these categories did not differ between red and yellow morphs but differed significantly within a morph (Table 1).

Table 1. Stylar length variation (in cm) in *Caesalpinia*

Flower type	Yellow		Red	
	<i>n</i>	Mean \pm SE	<i>n</i>	Mean \pm SE
Long styled	67	$5.67^a \pm 0.046$	56	$5.74^a \pm 0.048$
Medium styled	25	$3.79^b \pm 0.110$	20	$3.44^b \pm 0.143$
Short styled	44	$2.06^c \pm 0.058$	63	$2.09^c \pm 0.042$
Rudimentary styled	40	$0.65^d \pm 0.022$	67	$0.67^d \pm 0.020$

Mean values with same superscript (within a flower morph) do not differ statistically ('*t*' test significant $P < 0.001$).

Figure 1. Distribution of stylar lengths of *Caesalpinia* (Yellow morph – open circle; red morph – closed circle).

Table 2. Result of artificial crossing/selfing between the flower groups in *Caesalpinia*

Category	Fruit set
Long (self)	Yes
Long \times long	Yes
Long \times medium	Yes
Long \times short	Yes
Long \times rudimentary	Yes
Medium (self)	No
Medium \times long	No
Medium \times medium	No
Medium \times short	No
Medium \times rudimentary	No
Short/Rudimentary \times Long or medium or self	No

There was a clear spatial segregation of different styled flowers within an inflorescence (Figure 2). The flowers towards basal region were more often long styled, while rudimentary styled flowers were borne towards the upper portion of the inflorescence. The medium and short styled flowers were distributed in the middle region (Figure 2). Generally, the style length of the flowers reduced from bottom to the top of the inflorescence. Owing to acropetal blooming pattern, in any inflorescence long-styled flowers bloomed first followed by medium, short and rudimentary. The long-styled flowers constitute about 44% ($44.52 \pm 8.63\%$) of the total flowers in an inflorescence, medium $5.64 \pm 3.11\%$, short $19.54 \pm 4.80\%$ and rudimentary-styled flowers $30.63 \pm 7.98\%$.

The long-styled flowers produced mature fruits when pollinated with pollen derived from flower of any other stylar class as well as self pollen (Table 2). This indicates that the long-styled flowers are bisexual and pollen from all categories is fertile (Table 3). However, medium, short and rudimentary-styled flowers did not set fruits when they were pollinated from any other group or selfed hence function as males (Table 2). No differences

Table 3. Pollen size (value $\times 50$ microns), fertility (per cent) and ovule number (per flower) in different categories of flowers in *Caesalpinia*

Mean values with same superscript (within a morph) do not differ statistically but with different superscripts differ statistically ('*t*' test significant $P < 0.001$).

These results show that in *Caesalpinia pulcherrima*, four morphologically distinguishable flowers based on stylar length are produced within primary inflorescences (Figure 1). Further, *Caesalpinia* plants produce nearly 45% flowers within an inflorescence which normally set into fruits while 55% flowers are functionally pollen donors (Table 3). Hermaphroditic flowers require higher levels of energy for their construct and maintenance and also require higher energy during pod-filling stage when compared to functional male flowers (Table 4).

Interestingly, it was observed that if the basal long-styled floral buds were either removed intentionally or predated, the subsequent medium and short styled floral buds reverted to long-styled flowers and set into fruits (personal observation). This suggests that failure of fruit set in categories like medium, short and rudimentary may largely be determined by post-fertilizational events. Infact, competition for limited resources among developing pods has been shown to be severe in *Caesal-*

RESEARCH COMMUNICATIONS

*pinia*¹¹. Flowers with rudimentary styles never set fruit, because they are devoid of a normal style and stigma, however, the function of the ovules in this category is not known.

Caesalpinia produces energetically expensive flowers during early stages of inflorescence growth while less energetic and less expensive medium and short styled flowers at later stages might act as a reserve for the possible risk of floral predation^{12,13}. This developmental plasticity of floral function mediated by energy constraints may also be adaptive in increasing pollination efficiency. Because flowers are retained on the inflorescence for more than two days after blooming, the display size of an inflorescence would increase substantially when terminal flowers in an inflorescence are in bloom. This would also increase pollinator visitation, hence the plant may gain more through pollen export in the later stages of inflorescence growth^{14,15}.

Trondhjemite of the Alwar basin, Rajasthan: Implications of late Proterozoic rifting in the North Delhi Fold Belt

M. K. Pandit, Maher Khaled Khatatneh and Rakesh Saxena

Department of Geology, University of Rajasthan, Jaipur 302 004, India

Ajitgarh pluton, a minor granite–trondhjemite body, intrudes the Delhi metasediments of Alwar basin in the North Delhi Fold Belt (NDFB). The granite and trondhjemite, representing different pulses of anorogenic felsic magmatism, are distinct from the syntectonic granites of NDFB. The present work is also the first report of trondhjemite from Proterozoic environs of northwestern Indian peninsular region. Ajitgarh trondhjemite (AT) demonstrates trondhjemite mineralogy and chemical characters consistent with parameters prescribed for trondhjemite nomenclature. It is enriched in silica and depleted in CaO, MgO and FeO, as compared to the Archean TTG, and appears to be genetically related to the anorogenic magmatism of sodic affinity.

THE Trondhjemite–Tonalite–Granodiorite (TTG) association, a characteristic feature of the Archaean granite–

greenstone terranes, is hitherto unreported from the Proterozoic Delhi Super-group rocks from northern fringe of Indian peninsular shield. We report here the trondhjemite occurrence from a trondhjemite–granite suite from Ajitgarh pluton (27°26'N: 75°50'E), a minor intrusive body in the North Delhi Fold Belt.

Ajitgarh pluton, a composite granite–trondhjemite body, intrudes the sericite quartzite of Delhi Super-group. The geological set-up of the area is shown in the lithostratigraphic map (Figure 1). The contact between country rocks and the intrusive granitoids is obliterated by alluvial sand cover. Intrusive nature of the pluton is manifested by its emplacement discordant to the regional structural grain. Post-orogeny emplacement of granitoids is evident from absence of planar fabric, other textural characters and discordant nature of the pluton.

The generalized geological set-up of the area is summarized below:

Quartz–pegmatite veins
Granite
Trondhjemite
–Intrusive contact–
Sericite quartzite

The trondhjemite (AT), occupying the southeastern part of the pluton is in sharp contact with granite and

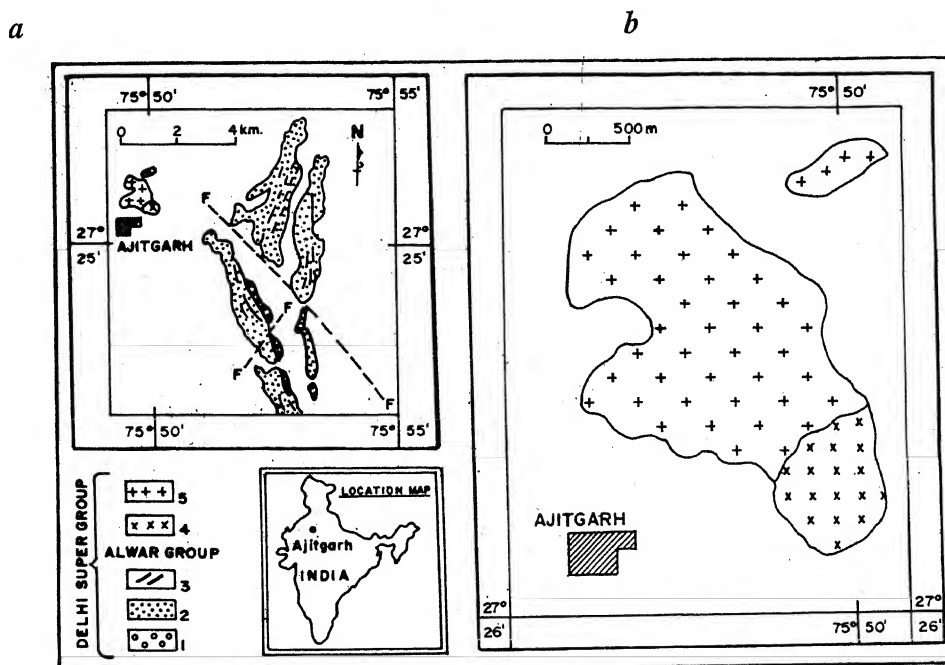

Figure 1. *a*, Map of Shahpura area showing regional lithological setting. *b*, Lithological map of Ajitgarh pluton showing distribution of trondhjemite and granite. Map of India showing location of Ajitgarh is also given in the inset. 1, Conglomerate; 2, Sericite quartzite; 3, Amphibolite; 4, Trondhjemite; 5, Granite.

Table 1. Modal composition of Ajitgarh trondhjemite

Sample no.	1	2	3	4	5	6	7	8	9	10
Quartz	39.5	38.0	43.0	45.5	47.0	44.5	40.0	47.5	44.5	45.5

Opaque	0.2	—	0.5	0.5	2.0	0.5	2.0	1.5	0.5	1.5
Others	0.5	0.5	—	0.5	0.3	0.5	0.5	—	—	0.5

Hb, Hornblende; Others: Allanite, Zircon, Epidote.

represents an earlier magmatic phase. Both trondhjemite and granite are dissected by younger tourmaline pegmatite veins.

Ajitgarh trondhjemite (AT) is a medium to coarse-grained holocrystalline, non-foliated, massive and compact, leucocratic rock with predominant hypidiomorphic granular texture. Major mineral phases are quartz and plagioclase (oligoclase) with minor alkali feldspar, augite and hornblende. Sphene is the most abundant accessory mineral besides less significant zircon, epidote and allanite. Biotite is conspicuously absent.

Quartz, the most abundant mineral, is present as equant, anhedral grains. Plagioclase (oligoclase), ranging from An_{24} to An_{14} (determined by Michel-Levy method) shows limited compositional variation. The plagioclase laths show moderate sericitization and also

demonstrate replacement relationship with quartz. Augite ($Z \wedge C = 24^\circ$), occurring as anhedral grains, invariably shows replacive relationship with hornblende. Subhedral hornblende grains are characterized by strong pleochroism in shades of dark bluish green to pale green ($Z > Y > X$). In majority of cases, hornblende shows perfect reaction texture with augite where it is seen mantling the latter. K-feldspar is mainly microcline microperthite with a few grains of orthoclase. Sphene is present both as rhombic crystals and as anhedral grains. In the hornblende free varieties, it is the only coloured mineral noticed. In majority of cases it appears to be a late crystallizing phase. Well developed zircon crystals are usually present as inclusions within larger plagioclase laths. Epidote, allanite and opaque are the other minerals noticed.

Figure 2. Modal QAP diagram of Ajitgarh trondhjemites. T, Tonalite; Gd, Granodiorite; MG, Monzogranite; SG, Syenogranite and AG, Alkali granite.

Figure 3. Na₂O-K₂O diagram showing tonalitic character of AT. 1, Tonalite; 2, Granodiorite; 3, Adamellite; 4, Granite.

Table 3. Comparison of AT with trondhjemite values

	Trondhjemites ¹	Ajitgarh trondhjemite (Present data)
SiO ₂	68–75%	73.27–78.65%
Al ₂ O ₃	<14% at 75% SiO ₂	12.07–12.96%
FeO(t) + MgO	<3.4	0.75–3.08
Na ₂ O	4–5.5%	3.96–4.80%
K ₂ O	<2%	1.38–1.66%
CaO	1.5–3%	0.53–1.51%

Paragenetic relationships indicate initial plagioclase–pyroxene crystallization, followed by separation of quartz and hornblende. Sphene and epidote mark the terminal phase of crystallization. The textural characters do not suggest any deformation as evident by equant nature of quartz grains, absence of preferred mineral orientations and absence of recrystallization.

Modal mineralogical composition of AT shows predominance of quartz and plagioclase (together constituting more than 80–85% of total rock volume) over other

Figure 4. Na_2O - K_2O - CaO diagram showing tonalitic character of AT. 1, Granite; 2, Quartz monzonite; 3, Granodiorite; 4, Tonalite.

Figure 5. Normative Ab-An-Or diagram showing trondhjemitic nature of AT. 1, Granite; 2, Granodiorite; 3, Tonalite; 4, Trondhjemite.

minerals (Table 1). K-felspar concentration is about 10% whereas augite and hornblende, together show minor variation from 1 to 4.5% (with one sample having a high value of 8.5%). Sphene concentration is quite consistent, varying from 0.5 to 3%. In the modal Q-A-P diagram the AT plot in the tonalite-granodiorite fields (Figure 2).

The trondhjemitic character of AT is further substantiated by chemical parameters. The major element data on ten representative AT samples are given in Table 2. Chemical homogeneity indicates their cogenetic nature. High $\text{Na}_2\text{O}/\text{K}_2\text{O}$ ratio (2.68 to 3.33) underlines sodic affinity. Appearance of normative corundum is attributed to low CaO and K_2O and does not indicate any alumina over saturation. Major element data for AT are within the prescribed ranges for trondhjemite and elemental abundances are coherent with typical trondhjemite values¹ (Table 3).

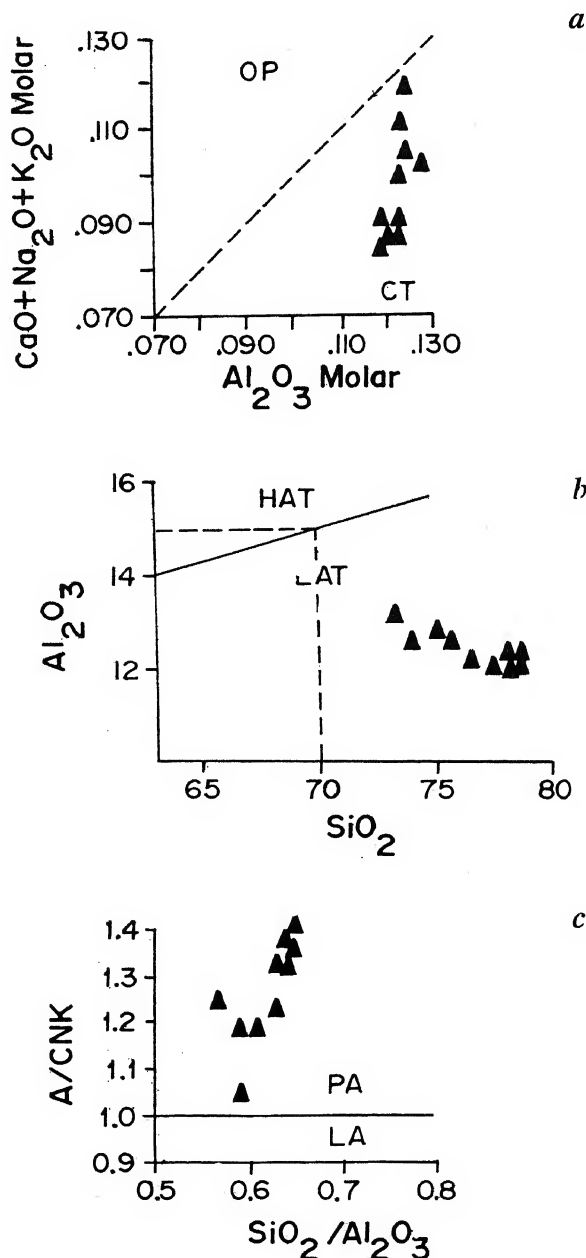

Figure 6a-c. a, Molar A-CNK diagram showing continental trondhjemitic affinity of AT. CT, Continental Trondhjemite; OP, Oceanic Plagiogranites; b, SiO_2 - Al_2O_3 diagram showing low alumina nature of AT. HAT, High Alumina Trondhjemite; LAT, Low Alumina Trondhjemite; c, A/CNK- $\text{SiO}_2/\text{Al}_2\text{O}_3$ diagram. PA, Peraluminous; LA, Low aluminous.

The AT shows slightly higher silica and lower CaO than prescribed for trondhjemitic rocks. The highest CaO value of 1.51 is at par with the lower limit for trondhjemite. An FeO/MgO ratio of 2 to 3 has been suggested for trondhjemite. In the present case the ratio varies from 1.33 to 12.73, with majority ranging from 2.54 to 5.06.

Alkali ratio has been a significant parameter in granitoid nomenclature and felsic rocks with sodic affinity

Figure 7. AFM diagram showing trondhjemitic trend.

Figure 8. Na-K-Ca diagram showing trondhjemitic differentiation trend for AT. Tdj, Trondjemite; CA, Calc-alkaline.

Figure 9. Normative Ab-Q-Or diagram showing trondhjemitic trend for AT. Tdj, trondjemite; CA, calc-alkaline.

($\text{Na}_2\text{O}/\text{K}_2\text{O} > 2$) have been named as tonalite². In the $\text{Na}_2\text{O}-\text{K}_2\text{O}$ and $\text{Na}_2\text{O}-\text{K}_2\text{O}-\text{CaO}$ diagrams³, AT plot in the tonalite field (Figures 3 and 4). In the normative

Ab-Or-An diagram¹ also, the AT shows discrimination with tonalite and unambiguously plot in the trondhjemitic field (Figure 5). Continental trondhjemitic affinity of AT is reflected in A/CNK ratio of > 1 . In the molar A-CNK diagram (Figure 6), these plot in the continental trondhjemitic field, quite distinct from oceanic plagiogranites⁴. In the A/CNK- $\text{SiO}_2/\text{Al}_2\text{O}_3$ diagram, these plot in the peraluminous field. In the $\text{Al}_2\text{O}_3-\text{SiO}_2$ diagram these plot in the Low Alumina Trondhjemitic field. The fields, proposed for a silica range up to 70% have been extended to accommodate silica-rich AT (Figure 6).

Trondhjemitic fractionation trend of AT is faithfully reflected in various sensitive discrimination schemes. In the AFM diagram, the AT plot along trondhjemitic trend (Figure 7). The distinction between classical calc-alkaline and trondhjemitic trends is also seen in Na-K-Ca and normative Ab-Q-Or diagrams (Figures 8 and 9) wherein the AT defines trondhjemitic path of descent.

Thus the mineralogical composition and chemical signatures establish the AT to be continental trondjemite, *sensu stricto*.

Trondjemites are characterized by moderate CaO, MgO and FeO for a given value of silica. A comparison of AT with Archaean trondjemites underlines broad chemical similarity although minor deviations are discernible. The AT are relatively enriched in silica and depleted in CaO, MgO and FeO, however, the alkali abundances are comparable. The average CaO abundance of 0.82% (range 0.53 to 1.51%) for AT is much below the usual values for Archaean TTG. However, a CaO value below 1% is not uncommon in Archaean TTG and CaO concentration as low as 0.29% has also been reported⁵. Relatively higher A/CNK for AT can be attributed to low CaO. The plagioclase in Archaean TTG is usually of oligoclase-andesine variety and in the present case the plagioclase (oligoclase) composition varies from An_{24} to An_{14} . Absence of biotite is a characteristic feature of AT. Minor biotite is usually present in Archaean TTG though pyroxene and amphiboles as the main mafic phases have also been reported.

Each felsic pluton has a distinct source and unique petrogenetic history, constraining any generalization. The difference between AT and Archaean TTG can be attributed to their distinct tectonic environments and evolutionary trends.

A 170 km long NNE-SSW trending lineament (extending between Khetri and Dudu), the 'albitite line' of Ray⁶, represents a post orogeny rejuvenation of the rift system that controlled Delhi sedimentation. This intraplate magmatism has tentatively been correlated with 800 Ma anorogenic event⁷. Instead of a single 'albitite line' the intrusion seems to be along a number of subparallel fractures⁸. The lineament passes to the west of Ajitgarh pluton in close proximity. Post-orogenic emplacement of AT, its anorogenic tectonic

environment⁹, sodic affinity and close proximity with intraplate sodic magmatism (albitite line) suggest a possible genetic link between two events. The relationship needs to be understood through detailed trace element and isotopic data.

SUBMISSION IN ELECTRONIC FORM

Authors who have been informed of acceptance of their manuscripts may send the final version in electronic form on floppy diskette (3.5" preferred; IBM PC format only, *not* Macintosh). The text of the manuscript only should be supplied as a plain ASCII file with no formatting other than line and paragraph breaks. (Wordstar 5.5 or 7.0 and Microsoft Word for Windows 6.0 are acceptable, but ASCII is preferred.) A hard copy of the text, with all typesetting information (italics, bold, mathematical type, superscripts, subscripts, etc.) must accompany the electronic copy. Tables and figures must be supplied only as hard copy. The diskette must be labelled clearly with the following: manuscript number, file name, file information (ASCII or Wordstar, version number, etc.).

Text may also be transmitted as ASCII only by e-mail to currsci@ias.ernet.in.

We expect that electronic submission will result in quicker processing for publication.

BOOK REVIEW

Quantum Biology by S. P. Gupta. New Age International Pvt. Ltd., 4835/24, Ansari Road, Daryaganj, New Delhi 110 002. 1996. 102pp. Rs. 250.

There is a never-ending demand for specialized text books, which can be easily accessible to research workers and post-graduate students. Although quantum biology is not a very new subject, the emphasis on use of different methods has changed from time to time. This was mainly due to progress in the computer hardware and availability of software at a reasonable price. Thus in the sixties people had access to 16 or 32-bit computers like IBM 1600, Honeywell 400 M, etc. and use of nonhomogeneous empirical methods as Del-Re method for σ and Huckel method for π electrons were popular. The most popular books were *Quantum Biochemistry* by B. Pullman and A. Pullman (Inter Science, New York, 1963) and *Electronic Aspects of Biochemistry* (ed. B. Pullman, Academic Press, 1964). In late sixties and early seventies, methods based on Self Consistent Field (SCF) theory approach with neglect of differential overlap as: Parriser-Parr-Pople (PPP), CNDO, INDO, etc. were developed and became popular because of availability of IBM 360, CDC 3200 and UNIVAC 1400 computers. The books *Approximate Molecular Orbital Theory* (J. A. Pople and D. L. Beveridge, McGraw Hill, 1970), *The World of Quantum Chemis-*

try (eds R. Daudel and B. Pullman, D. Reidel, Dordrecht, 1974) were found to be extremely useful. Much of the information was still available in good review articles like 'Organic molecule studies by semiempirical method', by Fonnandez-Alonso. The applications of biology were covered in books by Kier like *Quantum Pharmacology* (Academic Press) or *Molecular Orbital Theory in Drug Research*. Application of *ab initio* methods became popular with the availability of better IBM and CDC machines and computer programs through quantum chemical program exchange (QCPE) at University of Bloomington, Indiana, USA. There had been several short reports and even a dictionary of *ab initio* charges by Richardson was available. There had also been some specialized books like *Chemical Applications of Atomic and Molecular Electro-static Potential Molecular Electrostatic Potentials* by P. Politzer and D. C. Truhlar (Plenum Press, 1981).

Today the most important thing is to select the right method for a particular problem since lot of software is already available from commercial vendors as Biosym, Tripos Asso, Gaussian Inc. and also freely supplied as a public domain software. Hardware prices are reduced and their speeds have increased fantastically. The main difficulty for a researcher, especially of a biology origin, is to have training enough to carry out his work. Most of the time, the user is not interested in development of hard core theory or writing his own software.

He just has to know essential details of the methods and use in particular cases so that he can just pick up the method and do calculations. This demands more concise books which should be easy to follow. S. P. Gupta's book represents an ideal book for this purpose. It is concise and gives basic principle of ZDO approximation. He has enumerated essential details of CNDO, CNDO/1, CNDO/2, INDO, NDDU, PCILO, EHT, HMO, Del-Re, and Pariser-Paar-Pople method. He has given use of these methods for nucleic acids, proteins and phospholipids. He has also given a chapter on the use of these methods for quantum mechanics and transport in biological systems and drug-biomolecule interaction. The book is a perfect textbook for post-graduate and post-doctoral students in biomedical sciences. I only felt that the author could have given some information on *ab initio* method and molecular electrostatic potential maps, using different MO methods, their applications and some information on software packages. That would have benefitted the reader. The book on the whole is well written. The author and publisher have taken great efforts to set the mathematical equations.

Tadeus Reichstein (1897–1996) – An obituary

Tadeus Reichstein, Nobel Laureate and Foreign Fellow of the Indian Academy of Sciences, passed away on August 1, 1996 at the age of 99 years.

T. Reichstein was born on July 20, 1897 at Wloclawek, Poland. Due to unsettled conditions in Eastern Europe, he emigrated initially to Berlin and later to Zurich where he was granted the Swiss citizenship in 1914. Reichstein studied at the Zurich Technical University, graduating with a degree in Chemical Engineering in 1920. For his work on the odiferous constituents of coffee under the supervision of Hermann Staudinger, he was awarded the doctorate degree. This work formed the basis for the production of powdered coffee.

Reichstein joined the Zurich Technical University as a lecturer in 1930 in the new research specialty of physiological chemistry. He was promoted to assistant professor in 1934 and associate professor in 1937. During this period he worked on the structure and synthesis of carbohydrates, a field which he pioneered, especially in the crystallization of carbohydrates. During these years, his work on the synthesis of vitamin C involving an oxidation

process is noteworthy and several thousand tons of this vitamin are manufactured worldwide using his process. In

1938, he moved to Basel University as the head of the pharmacy department where he did the pioneering work on the isolation, structure, partial synthesis and biological effects of the adrenal cortex hormones and also cardiac

glycosides. Several corticosteroids were named after him. In 1950, he shared the Nobel prize for Physiology and Medicine for this work along with P. S. Hench and E. C. Kendall.

In 1950, Reichstein became the first director of the world renowned Institute of Organic Chemistry at Basel and retired in 1967. During the last 25 years, Reichstein became interested in chemotaxonomy and was responsible for the classification of ferns.

Reichstein received many honours and awards, the most important being the Royal Society's Coplay Medal (1968) besides the Nobel Prize for Physiology and Medicine. The Swiss Society of Pharmaceutical Sciences created the Reichstein Medal for excellence in pharmaceutical sciences in honour of Reichstein.

Reichstein had many Indian collaborators, most notably S. Rangaswami. Tadeus Reichstein married Lousie von Ufford in 1927, and is survived by a daughter.

Chandrasekhar – some reminiscences*

S. Ramaseshan

Introduction

Friends,

I consider it a great honour that I have been asked to deliver the bicentennial lecture of your historic Institute. For me the Indian Institute of Astrophysics has always been the home of Indian Optical Astronomy. It has been in the vanguard of building optical telescopes for India.

I first went to Kodaikanal when I was eight years old. The Kodaikanal solar telescope was the first telescope I had ever seen. I shall never forget the excitement I felt. Nor the thrill I got when I saw for the first time sunspots projected on a screen. I have visited Kodaikanal several times later. The old clocks of IIA at Kodaikanal have to be seen to be believed. The renovated Evershed hall – commemorating a great discovery – is beautiful. The 2.3 m telescope at Kavalur is a magnificent achievement. I now understand that the entire Institute is united in pursuing the goal of setting up a two-metre telescope and possibly a much larger one in Hanle or Ladhak which may prove to be one of the best telescope sites in the world. I wish you all luck. All this warms my heart. For I was closely associated with your Institute when it was formally formed; when it moved to Bangalore; and when the money for the Kavalur telescope, the dream of Vainu Bappu, was sanctioned. I feel quite embarrassed by the way I have been introduced by Prof. Cowsik, today, and more so with what is written in the brochure. He must have done much archaeological digging about me and my science.

Some time ago Cowsik requested me to give this bicentennial lecture. He said, 'It will be befitting if you talk about S. Chandrasekhar this year. He

was an Honorary Fellow of this Institute'. I too felt that Chandrasekhar would be an appropriate topic – as he was associated with an Optical Astronomical Laboratory – Yerkes – for almost 25 years. Cowsik requested me so earnestly that I should not say NO.

This reminds me of a cartoon in *New Yorker*. A middle aged lady is pictured surrounded by children of differing ages and of various nationalities, Japanese, Indian, Arab, Caucasian, African and so on. The legend says – 'she worked for the foreign service. Her problem was she could not say NO'.

I now regret having accepted this invitation. I was wondering what I should talk about – Chandrasekhar's science – How can anyone cover it in one hour even if one were competent to do so. There is Rajaram Nityananda's talk at IPA Madras entitled 'The six faces of Subrahmanyan Chandrasekhar' punning on the belief that God Subrahmanya is a six-faced god.

Should I talk about the great human being he was? Wali has done this in 325 pages. Then there are these wonderful articles by Abhay Ashtekar, G. Srinivasan and others again in *Current Science* – which I presume you have read – if not you must. I must be pardoned for mentioning *Current Science* again and again. For this has been my obsession for the last 6 or 7 years. Sometime ago I heard Radhakrishnan telling someone – 'I have known Ramaseshan for almost 60 years – we always discussed every subject under the sun – Optics and Astronomy, Physics and Aerodynamics, Cars and Gadgets, Planes and Gliders, Materials and devices, etc. etc., we have had a great deal of fun together. But now I find it a little difficult to talk to him. For instance if I tell him I saw a very pretty girl – so strikingly beautiful that it may even make his heart flutter.' Ramaseshan replies: 'That is very nice – can you write it up for *Current Science*'.

I can therefore talk to you only about my personal interactions with Chandrasekhar. That is why I gave the present title to this talk. Here again I

have a problem. Since he first left India in 1930 I have met him many times and after each meeting I have come back exhilarated. I have four files of letters we have exchanged. And providence has showered on me an unexpected gift – we became very good friends.

'I should not be writing this letter' he wrote 'if I were not sure of your long standing friendship'.

Even today this appears to me to be unbelievable. You can therefore understand my reluctance to wash linen in public even if it is not dirty. I fear also I may commit the cardinal error of making myself a central player. For what is Chandrasekhar's stature and where am I?

I have taken seven or eight incidents from my large collection which may possibly interest you and have prepared this talk. Three things I have to say. The incidents I relate are essentially correct. But memory can be deceptive. When I use the active voice, the words might not be the exact ones spoken at that time. Finally I lace the stories with my comments which you may ignore if you like.

The last conversation and his death

My last conversation with him was in July 1995. I called him up from Canada on my way to Montreal. We talked of many things for a long time. He said he had finally received the printed copy of his book on Newton's *Principia* – 'I like the cover. It is magnificent'. He had worked on this book for almost 5 years. 'My work is finished' he said. Did he see the figure of the Grim Reaper close by. On hearing that I was not going to Chicago due to reasons of my health, he asked almost in a wailing voice – 'Sivaraj (that is me) aren't you coming to see me?'. That question still haunts me – for within two months he was dead.

I was quite ill, when in the early morning of August 22 I got a telephone

*A verbatim account of the bicentennial lecture given at the Indian Institute of Astrophysics, Bangalore on March 14, 1996. Reproduced from *Bull. Astron. Soc. India*, 1996, 24, 537–550.

S. Ramaseshan is in the Raman Research Institute, Bangalore 560 080, India.

call telling me that he was no more – it was a few hours after his death on 21st in Chicago. I was calm – I phoned a few friends in USA. It appears he had a slight pain in the chest on the 19th morning. As it was on the right side he and Lalitha were not too worried. In fact so unworried that they even discussed, I am told, what they should do on the occasion of their 60th wedding anniversary which was to come a year later in September 1996. He phoned his sister who was in USA that he was preparing a series of lectures to be given at various universities. He therefore requested her to postpone her visit to Chicago by a week – he obviously died in harness.

On 21st morning after breakfast he drove to the University Clinic to get himself checked. Doctors told him that he was having a massive heart attack and were horrified that he had driven to the clinic himself. His car was not parked in the regular parking area but in the emergency one. One guesses that he had the heart attack during the drive. They phoned Lalitha. She came and was with him for 10 minutes. He was heard to tell her 'I think it is time for you to start making the preparations we had planned'. He died sometime later. It is almost certain he did not suffer much. He had stipulated that there should be no memorial service or meeting. He was to be cremated and no one was to be present and the ashes should be brought to Lalitha. As Plato says of his master the great Socrates, I quote:

Such was the end of a man who I think was the wisest and the justest and the best man I have ever known.

I was calm and collected. I told myself he was almost 85, he had become a legend in his time and was the greatest astrophysicist of this century. He had chosen perceptively fields which were seemingly unfashionable which later were to blaze new trails. He had produced 50 or more remarkable students who were dotted all round the world. He had written essays on science, literature, and the arts which were master-pieces. He had said to me – my work is finished and it seemed to me as though he had arranged with Providence for his passing away.

When I was invited to Montreal to speak at the memorial meeting for Dorothy Hodgkin (who also considered me a friend) – Kausalya, my wife, said

that on no account must I break down and cry before a western audience.

Today she told me: you have a good Indian audience, familiar with Kannada, Tamil and Hindi films: you could therefore break down and cry, if you wish!

Polarization of the sunlit sky

I met him first when he came to Calcutta to bid goodbye to my mother on the eve of his going to England in 1930. I was then less than seven. Again in Calcutta when I was 12 years old, I heard his lecture at the Indian Association for the Cultivation of Science. He wore the traditional cylindrical dhoti and a coat which was to become his standard dress whenever he was in India. I still remember him mentioning a mnemonic used for classification of stars. O BE A FINE GIRL AND KISS ME RIGHT NOW SALLY.

Fifteen years later in 1951 when he came to Bangalore he was received at the airport by C. V. Raman. He came to lunch at our little house at the Indian Institute of Science, I was recently married. He was full of laughter, made fun of us, quipped with Kausalya and discussed with her sari fashions.

I think it was then that he told us of the experiences he had in Russia. The following story he told us is the same he also related at a party in his house in Chicago.

He was shocked when he had to share a small cabin with three women in a boat during his North Sea passage to Russia. The women too were horrified. They developed an elaborate ritual for undressing so that the man would have no opportunity of seeing them undressed. They all undressed and went to bed. The women insisted on keeping the little port hole window open so as not to make the cabin too private! North Sea became quite rough as it normally does; even then the women refused to permit Chandrasekhar to close the port hole. Finally a very big wave came and splashed into the cabin through the port hole and drenched them; all jumped out of their beds in a state of undress. When Chandrasekhar told this story everyone at the party laughed. There was a woman post doc who said, 'Are we to take it Chandra that you had a shower with three undressed women at the same time – it was very very naughty of you'. This provoked an immense roar of laughter.

In many of the stories that Chandrasekhar told he was often the target of the joke*.

He told us how he had met a large number of brilliant astronomers and physicists in Russia. All of them were later sent to Siberia, purged or executed. Landau and Ambartsumian were the exceptions – thanks to the heroic intervention of Peter Kapitza.

The next day he gave a lecture 'On the polarization of the sunlit sky'. It was perhaps the best scientific lecture I have ever heard. It was the pinnacle of his monumental work on Radiative Transfer. He told us how he got interested in this problem – the problem of the atmosphere of a star. The need to treat coupling by photons of the different layers with varying properties. He told us how the principle of invariance was evolved – following the work of the Armenian astrophysicist Ambartsumian I referred to earlier (in Russia from his first name in the passport he was often taken for an Armenian as it had the same ending – Subrahmanyan – Ambartsumian) – He developed 'invariant embedding'. This he applied to explain the polarization of skylight – the radiative transfer in a finite slab of air which scatters the sunlight in the sky. He went back to the Great Masters, he discovered Stokes' paper published in late 1870s from which he obtained the Stokes parameters for the description of polarized light. He formulated integral equations which were so complex that even very good mathematicians would have abandoned them. To quote Rajaram Nityananda 'He talked to these equations personally and intimately till they gave up their secrets'. It is a saga that has to be heard or read to be believed. At the end of the lecture Raman who was in the audience commented 'Rayleigh formulated the theory of light scattering to explain the blue of the sky in 1871. For eighty years the problem of the experimentally observed complex polarization of skylight has defied the efforts of the great masters. Today we have had a most extraordinary exposition by another Master. We have heard how the problem was solved by the combination of physical intuition and powerful mathematical analysis.' Then he asked: 'Professor Chandrasekhar can you tell us how long it took you to work out the results which you have pub-

* I have heard many versions of this story but this is the one I like best.

lished in the four-page paper in *Nature*?. Chandrasekhar after some thought answered 'More than two and a half years'. That issue of *Nature* (1951) had not reached Bangalore then. But Chandrasekhar, as was his habit, had sent a reprint or preprint by airmail to Raman.

One realized that if one had some previous knowledge of the subject (as I had on polarization of light and the Stokes parameters, etc.) one can get much more from an outstanding lecture by one like Chandrasekhar. But the awful disadvantage is that such a lecture exposes one's inadequacy unforgettingly.

I jump 35 years – as this relates to another Indian who was also an expert in the same field. Chandrasekhar once wrote to me:

Stimulated by the handsome references to Pancharatnam by Michael Berry, my colleagues and I are interested in the *Collected Works of Pancharatnam*, I should like to buy a copy.

I sent him a complimentary copy of the *Collected Works*. As the High Priest of Polarization Optics of this century I asked him whether he would be inclined to write for the Pancharatnam issue of *Current Science*. He wrote,

I am too far away from this subject – It is almost 45 years since I even thought of Polarization of Light. Further I may not have anything worthwhile to say. However I always congratulate myself that when I read Pancharatnam's classic paper long ago I did recognize its merits.

Time does not permit me to talk to you about my meeting him in Yerkes in 1954; his accounts of his collaboration with Enrico Fermi, Fermi's death which had occurred just a few weeks earlier (He told me the well-known story of the elephant which all of you must have heard). How he decided and took the US citizenship in 1953 (without consulting his father). 'Now Lalitha has been appointed as the peace maker' and he told me of her efforts to appease the old man. I remarked 'You coward'. He told stories of his and Raman's encounter with colour prejudice in USA, his introducing me to Otto Struve, whom Blaauw described as the man who knew all of astrophysics, and many other stories. I shall never forget this meeting.

Einstein's view of God

I mentioned that he and I had exchanged many letters. I give an example which illustrates how meticulous he was in answering questions asked of him, the effort he takes to make his listeners understand, his consideration and his strong views.

'I am writing this letter, however, with respect to two questions you asked of me at the airport prior to our leaving Bangalore a week ago'.

First, with regard to Einstein's different views of God: in 1919 when he said 'I would be sorry for the Lord' and his later statement in the late twenties 'God does not play dice'.

Chandrasekhar was always uncomfortable when the word God was mentioned. The letter contains a few typed pages and has some equations. His argument is that the same metric (using the post-Newtonian approximation) gives the precession of the perihelion of mercury to be 43 seconds of arc per century and the deflection of light grazing the Sun to be 1.75 seconds. A theory which is consistent with one crucial test, if it fails in another – then one would be justified in being sorry for the "Lord". 'Ignoring the word 'Lord' I do not think anyone would disagree with what Einstein intended to say.'

'Your second question really concerns the spin of the photon. That the photon must be associated with an angular momentum $s = 1$ which is as old as Einstein's concept of the photon (remember the weight 2 in Planck's formula).' Then a long discussion follows on Bohr's correspondence principle, Rubinovicz' derivation, the demonstration of the spin of the electron by the Mottdouble scattering experiments and the need for explicitly demonstrating the spin of the photon etc., etc. He ends the letter by saying,

I hope you will not consider me too impertinent, if I quoted Eddington in this context. In the off chance that posterity may find wisdom in our words is no reason for making meaningless noises.

In another context, he wrote: 'Einstein's judgment on the uncertainty principle is one of personal conviction only. It is not any reasoned scientific argument. His later official judgement on the quantum theory does not invalidate his own personal conviction of the truth of

general relativity.'

Wali's biography and Raman

He asked me once what I thought of Wali's biography.

'It is a remarkable biography. It reads like a novel'.

'Do I detect a slight undertone of disapproval' he asked.

'Yes, I do not like those parts where by implication it is derogatory to you'.

'Derogatory to ME' – the Me became a high monotone – reminding me of his uncle. I think he could not believe, that Wali his Votary, could have said anything derogatory to him.

'When Raman offered you a position at the Indian Institute of Science in 1935 – you wrote to him a very fine courteous and what I consider to be an honest letter; that you were flattered, you were not sure whether you would fit into an experimental group and finally you were afraid that the media attack against Raman would increase if you, his nephew, were appointed. And this may affect your performance as a scientist. Therefore you were, with great regret, not accepting his offer.' Wali, on the other hand, has written it in such a way that one gets an impression that you were really responding to your father's request to stay away from Raman. This implies the letter was a false one – that you were dissimulating. I have now known you for a long time. I cannot imagine you dissimulating or playing the hypocrite.

Chandrasekhar was silent for some time and said with a smile,

I did not write the biography it was Wali who did.

Chandrasekhar was always reluctant to talk about Raman. I once cornered him and made him speak on this topic.

In your letter when Lalitha and you presented Ramanujan's bust you say:

As a companion to the bust of Raman so that the bust of the greatest physicist of India could be along with that of the greatest mathematical genius of our times who happened to be an Indian

'Do you really think Raman was the greatest physicist of India?'

'Of course I have no doubt on that

score – and you yourself have sometime ago given me a certificate that I do not dissimulate.'

People in India remember him for the discovery of the Raman Effect which won him the Nobel Prize. One discovery advances science, but it cannot be a criterion to judge the quality of a physicist. Raman's work on acoustics is first rate – his work on the violin is considered a classic even today. Acousticians wonder how he could have done these beautiful experiments and theories in those days. In optics he was a Master, in the class of Rayleigh and Michelson. It is a great pity his *Lectures in Physical Optics* which I used for giving an advanced course in Optics is not widely known.

His Nobel Prize, in my view, retarded his science – probably it was because the effect it had on his psychology, I may be wrong. Even so his later work on Brillouin Scattering and crystal transformations are again world class. One feels sorry he committed major errors in his latter life – and he became aggressive too. Unfortunately this is what many remember him by, not the excellent physics he did earlier. I consider him to be a brilliant classical physicist who made a spectacular experimental discovery of a quantum mechanical phenomenon. It has influenced physics, chemistry and even technology as he predicted in his Nobel Lecture.

Most of the other Indian physicists of repute, of those days, had practically no outstanding students. On an invitation from CSIR I had the opportunity of visiting a large number of laboratories and scientific institutions of India. I realized Raman's contribution to the growth of Indian Science and Technology, after India's independence, was also in the form of students. Many of them had established very competent research schools – many had headed and built laboratories. They must have imbibed from him the spirit of science for they, in turn, produced excellent students.

'How do you rate Raman by world standards?'

'As an experimental physicist'

'Yes'

'For that we have to compare him with men like Rutherford and Fermi – the answer is obvious'.

'If that is the yardstick you use would not all experimenters of the world except perhaps those like Michael

Faraday fall by the wayside?'

After some thought he remarked: 'Yes, that is probably true.'

He enters general relativity

The following story was told to me by Chandrasekhar himself. He wanted to go to Warsaw to the Conference on General Relativity which was to be attended by the established figures in the field like Richard Feynman, Leopold Infeld, Paul Dirac and the younger ones like Roger Penrose and Ted Newman. The National Science Foundation wanted to support his travel. He did not fit into the standard categories they had.

Q1 Are you chairing a session NO

Q2 Are you giving an invited talk? NO

Q3 Are you making a presentation? NO

Q4 Are you an expert? NO

I want to be there as I am seriously thinking of entering the field of General Relativity. They found an appropriate excuse to give him travel funds.

A friend of mine was visiting Chandrasekhar. They were walking down the corridor. Suddenly he saw someone coming at the end of the corridor. He was a young man, wearing dirty torn jeans. Chandrasekhar was of course immaculately dressed, in his charcoal grey suit, handsome as ever. He straightened up his tie, went forward at a fast pace, greeted the young man, shook his hand, talked to him for some time, opened the door of the car and the young man got in and drove off. Chandrasekhar came back and joined my friend who asked 'who is that hippie?'

'He is Geroch.'

'Who is Geroch?'

'He is one amongst the most outstanding relativists of today – he is in his twenties. I have invited him to lecture in Chicago this summer. I am attending his course. It takes me the entire weekend to work out and understand some of the equations he puts on the black board – to be ready for his Monday lecture. When I am stuck. I ring him up, even if it is late at night, to bail me out.'

At 60 he was humble enough to learn

relativity from youths, at 70 held his head high amongst the brilliant young relativists. At 80 he was respected by all for his unparalleled contributions to General Relativity.

It was about this time that Chandrasekhar told me

The trouble with Einstein was that he did not believe sufficiently in the Theory of General Relativity.

I honestly felt that he was going gaga. Many years later after he wrote his monumental treatise on Black Holes I told him of the fears I had. He laughed loudly in his characteristic way.

It was later when Abhay Ashtekar wrote the following that I understood what Chandrasekhar meant.

'If Einstein had believed in his general relativity sufficiently and deeply enough, he would have worked out the consequences of the nonlinear aspects of the theory in the strong field regime. Chandrasekhar believed that Einstein was the *only* person who could have done this at that time. Then General Relativity would have entered the mainstream of physics four decades earlier.'

Chandrasekhar told me that many authors had not considered the gravitation radiation reaction in General Relativity. 'When all my old problems were reexamined, very unexpected results turned up. For example I was able to show that all rotating stars are unstable due to radiation reaction.'

Abhay Ashtekar says:

Chandrasekhar more than anyone else played a decisive role in bringing the beautiful creation of Einstein to its natural home – Astrophysics, and

His intuitive feeling that the radiation reaction in general relativity is important is one of the deepest insights in relativistic astrophysics.

Music, literature and the arts

Chandrasekhar's appreciation of Music, Literature and the Arts was staggering. He mastered each of these fields in his own way. He heard each of the symphonies of Beethoven and the Operas of Wagner many times. His attachment to western music was both intellectual and emotional.

Often he read out to us pieces from poetry and prose which he liked. His

readings from T. S. Elliot were delightful. When he read passages from Virginia Woolf in his sing song voice you felt you even understood this rather difficult author. But I think it was Shakespeare that he loved best. He must have read every play of Shakespeare many times. He could lecture on any play better than any Oxford don – especially Hamlet and Tempest. I think Shakespeare gave a sort of direction to his life. He often told me that reading Tempest helped him in the attitude he had in doing research. I can easily imagine Chandrasekhar to be Prospero of the Tempest. If I now allow my imagination to run riot: Like Prospero he was –

Far away in a distant land – nursing a grievance and – biding his time for vengeance.

Then he was –

Drawn deep into books – succumbing to his overwhelming thirst for knowledge – and in splendid isolation – taking long years of preparation – and long years to perfect his art.

He discovered to his amazement –

The more he pursued his science (Shakespeare calls it the enchanted arts), the more single minded he became in its pursuit. Thus finally it cleansed him as it did Prospero.

When the time did come, a transformation had already taken place and like Prospero he had become free. His grievance was gone and he had no desire for vengeance.

However, I think what finally liberated him and his soul was his complete surrender to his god – whom he called 'The unmatched and unmatchable Newton'.

It would be impossible for me to convey to you the thrill and excitement of the exposition he gave us on Newton's *Principia* on one of our visits to Chicago. Almost true to his chosen title, *Newton's Principia for the Common Reader*, he lectured to Kausalya the Common Woman. I felt that he was really constructing the sentences that he was to write in the introduction two years later. We cherish a photograph of Kausalya and Chandrasekhar which I took. He is holding Cajoris 2nd edition of the *Principia* which he had bought for Eight Thousand Dollars.

Once when we were in his drawing room Kausalya asked 'Is that a Monet?',

'Yes – only a print – I cannot afford an original'. He told us that a chance remark by Roger Penrose that his excursions into General Relativity reminded him of the series paintings of Monet – triggered him off. It is the same Monet – whose Sunrise – an impression started the impressionist movement. He studied everything written about Monet and by Monet. He collected excellent prints of all his paintings – especially the Series Paintings of Haystacks, Poplars and Mornings on the river Seine. His word pictures of these paintings were such that he could make us see things we would not have seen otherwise.

I feel I am exploring the landscape of the mathematics of General Relativity as Monet explored his Haystacks which took new forms in the changing colour of light during the day and during different seasons.

He showed us how in Monet's poplars and their reflections were vertical lines while the tops of the other trees appeared near horizontal lines forming a wavy and beautiful grid – such exquisite wavy grids, according to him, inspired newer trends in geometric painting like those of Mondrian.

'The parallel in physics is', he said, 'just as the quantum theory of scattering of gravitational waves by stars led to a deeper understanding of the theories of scattering themselves'.

We sat there with our mouths open. It was an entrancing half hour. We can remember almost every word he spoke. Did we understand whatever he said. We do not know. His enthusiasm, his sparkling eyes, the cadence of his voice remained with us for a long long time.

Basilis Xanthopoulos

My visits to USA were never for more than 10 to 12 days. A day in Chicago was a must. I phoned him once. He said, 'I am flying over to meet Roger Penrose this evening. Can you come after three days?'. I went on the specified date. He received me at O'Hare airport. I again felt greatly privileged.

He was at that time probably working on black holes and cosmic strings.

Whenever I come across a stumbling block I go and meet Roger Penrose. We spend an hour together early in the morning when I present him with my problem. We have 4 to 5 hours of

discussion after lunch, then dinner, when we talk of other things – and I fly back. In no case has he not cleared up my doubts in physics or mathematics. An amazing man.

Chandrasekhar always followed where his mathematical and aesthetic instincts led him. During this period he collaborated with Basilis Xanthopoulos in Crete and Valeria Ferrari in Rome. He visited them often – but never for more than four or five days. It was with them that he discovered the underlying similarity between the mathematical theory of black holes and of colliding gravitational waves. We at the Raman Research Institute had the privilege of listening to his latest work which had not yet appeared in print. On every occasion during his formal or informal lectures, he mentioned with gratitude and affection Basilis Xanthopoulos and Valeria Ferrari.

So when I read the horrible story that while lecturing at his University, in Crete, Xanthopoulos was murdered by terrorists, I wrote to Chandrasekhar a condolence letter. He was touched and he wrote: 'My association with Basilis was the most enduring personal relationship I have had in all my 60 years in Science'. He also sent the foreword Basilis had written to Volume 6 of his collected works; This was published in *Current Science*.

When we met him next time and I referred to Xanthopoulos' death, we could see in his eyes the agony that I saw in my father's when he lost his much loved son. I realized then more than ever that those like Basilis Xanthopoulos and Valeria Ferrari were truly his Children – Children that he and Lalitha never had.

Return to India?

The following episode extended over four or five meetings in Bangalore, Chicago and Cambridge. I will try to give a connected account.

One day I asked him – you say in an essay you wrote about 30 years ago:

I have been a foreigner all these years except for a brief vacation for eight weeks when I was in India. By foreigner I mean that I have never been allowed to feel otherwise. Yet people from other countries migrate to distant

lands, build homes on new soils, adopt and are adopted by their neighbours. But why is it not so for me, an Indian.

I then asked 'has that feeling changed now?'

'Unfortunately no, I thought it would when we become citizens of USA in 1953. But even today I feel at home only in India. I think it is a great pity – why do you ask?'

I always poke my nose into other people's business. If you feel I offend you, stop me. Have you ever thought what will happen to you if Lalitha dies – and what will happen to Lalitha if you die. For I feel the US can become a very very lonely place.

(I remember he and Lalitha most graciously visiting the great physical chemist Mulliken. They took me with them. Mulliken was suffering from Alzheimer's disease. There was literally no one with him and Lalitha had to make tea for all of us.)

'Have you a solution?'

'Yes, I have.' Why don't you come back to India. Bangalore would probably be the best place. You can be at the Raman Institute. People always say RRI means Raman's Relatives Institute. He said 'some of his relatives who were at RRI have been very able scientists – of world renown'. I said, 'please do not interrupt me at this stage' and I continued. 'It would be nice if his most distinguished Relative can also be at RRI. You can stay with your brother who is in Bangalore. But it may be better for you and Lalitha to be in a cottage maintained by RRI or its Trust. It will provide you with help, transport, etc. You can invite any of your collaborators to Bangalore. Now and then, if you so desire, you can give courses of lectures. I can assure you very bright young people, and they are in plenty in India, will swarm around you. You can select the best of them to work with you. You would also be fulfilling Radhakrishnan's dream of having a Gravitation and General Relativity Group'.

He said 'I have also been thinking about this problem', and always the gentleman, he said 'It is most gracious of you to have thought of me and to have invited me. The offer is very at-

tractive. I shall surely think about it'.

I informed Radhakrishnan that there were chances – even though slim – of his accepting our offer. So a part of the new building was redesigned – special permission was obtained to put a lift – for Chandrasekhar had had his share of heart attacks and heart surgery.

He told me later he had given some careful thought – 'The only other place I could have considered was Oxford, because Roger Penrose is there. But there are some difficult conditions. Firstly, *I would not like to give up my US citizenship – for it was the US that gave me conditions that made my work possible, conditions which I could not have got anywhere else.* Secondly, I am not a rich man. I would get a pension. We need money to travel to conferences, to meet my colleagues and my collaborators. I am told that the Indian tax laws are formidable'.

I knew nothing about tax laws. I consulted the best people – the private and Government experts, I met persons at the highest levels. I was assured that Chandrasekhar could retain his US citizenship, even if he lived in India. They also assured me that steps could be taken to see that he was exempted from paying tax during his lifetime. Even an annual grant could be given to RRI for the sole purpose for the maintenance of Lalitha and he and for his research, travel, etc. I conveyed all this to him. At that time he had finished his work on Black Holes and had started his work on the collision of gravitational waves.

In 1983 he was awarded the Nobel Prize. I wrote him a congratulatory letter – also saying that my children were ecstatic, RRI and indeed the whole country were thrilled about it. A month later in January 1984 he phoned me saying that he would be accepting my invitation to give the inaugural address at the Golden Jubilee of the Indian Academy of Sciences – and that he was preparing an essay specially for the occasion. I was greatly excited.

He also conveyed the sad news that after getting the Nobel Prize it would be ungracious and appear ungrateful if he should leave the United States. Again a perfect Gentleman! He went on to thank me for all I had done and apologized that all my efforts came to naught.

Conclusion

In conclusion I say:

'There were two faces of Chandrasekhar, the stern aloof, and difficult to approach person and the kindly charming laughing human being dispensing jokes and anecdotes.'

'He had an inexhaustible supply of anecdotes – from his own association with scientists and from the history of science. He never repeated the same story to the same individual – For he had a phenomenal memory.'

'Each time you talked to him he opened up a new door for you and you saw a new vista – a new surprise'.

I was always flattered that he listened so intensely to one such as me. When I look back I shudder to think that I lived when he lived, that I knew him and he befriended me. For me this was the proof of the theory of Karma. I must have done something good long long ago.

About his science he said once 'I work on my own for my personal satisfaction generally outside the scientific mainstream'. It always became the mainstream a few years later. His earliest work led to the concept of the neutron stars and black holes. His survey of Brownian motion started new fields, many not at all related to astronomy. His concept of Dynamical Friction has become as much a part of the astrophysics vocabulary as the Chandrasekhar limit. With his work on Radiative Transfer began a brand new field in mathematics called invariant embedding. His ellipsoidal figures of equilibrium have become important to fast-rotating pulsars. One can go on and on.

His prescience in taking up any problem makes one gasp.

Believers would say – 'he was touched by the hand of God – a touch that remained with him till he died'. This of course would have made him very uncomfortable and even annoyed.

But there are simpler explanations. For him, like Srinivasa Ramanujan, doing science was like breathing. He did what he could not help doing – As the poet said:

'As in yonder valley the myrtle breathes its fragrance into space.'

MEETINGS/SYMPOSIA/SEMINARS

X Southern Regional Conference on Microbial Inoculants

Date: 10–11 December 1996
Place: Poondi

Sessions include: 1. Field applications of bacterial, algal and mycorrhizal inoculants, 2. Production problems, 3. Marketing problems, 4. Farmer's views on inoculants. Satellite meetings will also be conducted on biocontrol of pests and diseases, Training programme on sugarcane specific microbe *Acetobacter* species for sugar industries, Training cum awareness programme on biofertilizers for PG and research students on 12, 13 and 14 December 1996, respectively.

Mathematical and Theoretical Models in Biology

Date: 12–19 January 1997
Place: Puri

Applications are invited for participation in a workshop-cum-discussion meeting sponsored by the Department of Science and Technology to be held at Puri from 12 to 19 January 1997. The aim of the workshop is to expose advanced post-graduate students and young research workers to models in a whole range of areas in biology including immunology, developmental biology, genetics and behaviour. Participants are expected to be familiar with mathematical techniques at about the P. U. C. (12th standard) level.

Selected participants will have their travel (II class return rail fare) and living expenses at the venue of the workshop covered. A brief c. v. and statement of reasons for wanting to attend (within half a page) should be included. The last date for receipt of applications is 15 November 1996. Selected participants will be informed by the second week of December. Those interested should write to:

Dr V. Nanjundiah
Developmental Biology and Genetics Laboratory
Indian Institute of Science
Bangalore 560 012
Fax: 91–080–3341683

National Workshop on Remote Sensing and GIS Applications for Watershed Management

Date: 21–22 January 1997
Place: Bhopal

Themes include: 1. Applications of Remote Sensing and GIS in – a. Geology and Geomorphology, b. Landuse and Urban planning, c. Forestry, d. Soil and Agriculture, e. Environment, f. Water

resources. 2. Application of Remote Sensing and GIS techniques as a tool in watershed management.

National Symposium on GIS and Geological Remote Sensing

Date: 5–7 February 1997
Place: Tiruchirapalli

Themes include: Applied remote sensing in – Spectral behaviour of rocks and minerals, Digital image processing in geosciences, Lithological mapping, Structure and tectonics, neotectonics and seismotectonics, Geomorphology, Mineral and hydrocarbon exploration, Water resources, Engineering and environmental geomorphology, Geohazard zonation mapping and Geographical Information System.

National Conference on Energy Crisis and Environment

Date: 7–8 March 1997
Place: Chennai

Topics include: Non-conventional energy, Environmental energetics, Environmental Bio-technology, Environmental engineering, Environmental chemistry, Environmental management, Environmental ethics.

Contact: Dr Francis P. Xavier, SJ
Convenor/Director

Symposium on Tropical Crop Research and Development, India – International

Date: 9–12 September 1997
Place: Pattambi

ISTCRAD (International Society for Tropical Crop Research and Development) is organizing this symposium. Critical analysis on research/developmental activities in all the tropical crops are included in different sessions. Concurrent sessions are arranged

for all the disciplines including basic and applied research in agriculture and allied subjects.

UK/INDIA SCIENCE AND TECHNOLOGY RESEARCH FUND

Department of Science and Technology (DST) of the Government of India and the Office of Science and Technology (OST) of the British Government jointly invite applications from scientists for financial support under the Indo-British Science and Technology Research Programme to develop and implement joint projects in specific areas of Telecommunications and Associated Information Technologies, Agro Food and Advanced Manufacturing Technologies.

Whilst considering proposals, particular importance is attached to scientific merit, value of money and likely long-term industrial relevance. Preference will be given to projects with clear industrial relevance or identifiable industrial potential. The participation will be taken automatically as evidence of such relevance.

Financial support will be limited to international travel. Funding for equipment, bench fees, institution overhead, etc. will not be provided under this programme.

Application forms along with the guidelines for S&T collaboration may be obtained from:

Programme Office,
International Division (UISTRF),
Department of Science and Technology,
Technology Bhavan, New Mehrauli Road,
New Delhi 110 016
Phone: 667373/662135
Fax: 6862418/6863847

British Council Division (UISTRF),
British High Commission,
17, Kasturba Gandhi Marg,
New Delhi 110 001
Phone: 3711401/3710555
Fax: 3710717

Request for applications may be made latest by 15 November 1996 along with a self-addressed envelope (12 cm × 27 cm). The project proposal completed in all respects should be submitted latest by 15 December 1996.

Current Science, founded in 1932, is published by the Current Science Association in collaboration with the Indian Academy of Sciences. The journal is also intended as a medium for communication and discussion of important issues that concern science and scientific activity. All articles published in *Current Science*, especially editorials, opinions and commentaries, letters and book reviews, are deemed to reflect the individual views of the authors and not the official points of view, either of the Current Science Association or of the Indian Academy of Sciences.

INFORMATION FOR CONTRIBUTORS

GENERAL

All manuscripts should be addressed to the Editor, *Current Science*, P. B. No. 8001, C. V. Raman Avenue, Bangalore 560 080. Submission of an article will be held to imply that it has not been previously published and is not under consideration for publication elsewhere; and further, that if accepted, it will not be published elsewhere. *Three copies of contributions of all categories* are required, with a letter of transmittal giving (i) names and complete addresses of the authors and (ii) title of the contribution and the category in which it is submitted (see below).

Current Science is a multidisciplinary journal and therefore research and review papers of general significance that are written clearly and well organized will be given preference. All papers will be first assessed by a Reviewing Editor. Papers found unsuitable in terms of the overall requirements of the journal will be returned to the authors. The others will be sent for detailed review. *Both solicited and unsolicited material will be reviewed.* Authors of these papers will be notified of acceptance, rejection, or need for revision of the paper. Returned papers cannot be resubmitted. Illustrations and other material to be reproduced from other publications must be properly credited; it is the authors' responsibility to obtain permission for reproduction (copies of letters of permission should be sent).

CATEGORIES OF MANUSCRIPT

General articles (not exceeding 5000 words) discuss current trends in research in a field that will be of interest to readers outside the field; interdisciplinary topics: science policy and administration; or some aspect of the application of science and technology to human needs or the impact of science and technology on society/ecosystems/life. They should include a summary not exceeding 100 words, introductory paragraph(s), brief subheads at appropriate places to point to what follows, illustrations that will help a general reader, and references.

Review articles (not exceeding 5000 words) are expected to survey and discuss recent developments in a field. They should be well focused and organized, and avoid a general, 'textbook' style.

Research articles (not exceeding 4000 words) should report research results of fairly major significance. They should include an abstract not exceeding 100 words, introductory paragraph(s), and brief subheads.

Research communications (not exceeding 2000 words) should contain important findings that are novel and of fairly broad interest. They should include a brief abstract and an introductory paragraph. Text should not be broken up under subheads.

Correspondence includes letters, not exceeding 500 words, that are of general interest to scientists. All letters cannot be published.

Scientific correspondence contains technical comments, including those on articles or communications published in *Current Science* within the previous six months. Letters may be reviewed and edited.

Research news articles are intended to inform nonspecialists about recently published advances or important findings discussed at a meeting. Authors should also send a copy of the paper(s) on which the article is based. Meeting reports should avoid merely listing brief accounts of topics discussed, and must convey to readers the significance of an important advance.

Research accounts articles are intended to be personalized reviews of research from the authors' own laboratory, based on a body of published work. The articles must provide appropriate background to the area in a concise introduction, which should also serve to place the author's work in proper perspective. Articles will normally

not exceed 8 to 10 printed pages.

Opinion articles present views on issues related to science and scientific activity. **Commentary** articles should contain expository notes on issues related to science and scientific activity.

Book reviews. Unsolicited reviews will also be considered. Reviews that merely 'list' brief descriptions of the contents cannot be published. Reviews should have 'context' and convey some information about the subject of the book.

Historical commentary and notes inform readers about interesting aspects of personalities or institutions of science or about watershed events in the history/development of science; most are expected to relate to India. Illustrations are welcome. Brief items will also be considered.

MANUSCRIPT PREPARATION

Manuscripts should be typed double-spaced on one side of white bond paper (21 × 28 cm). The pages should be numbered consecutively, starting with the title page and through the text, reference list, tables and figure legends. The title should be brief, specific and amenable to indexing. Not more than five **keywords** should be indicated separately; these should be chosen carefully and must not be phrases of several words. **Summary** and **abstract** should not have more than 100 words and should convey the main point of the paper, outline the results and conclusions, and explain the significance of the results.

Text. All papers should have a brief introduction. The text should be intelligible to readers in different disciplines and technical terms should be defined. Tables and figures should be referred to in numerical order. All **symbols** and **abbreviations** must be defined, and used only when absolutely necessary. Superscripts and subscripts and ambiguous characters should be clearly indicated. **Units of measure** should be metric or, preferably, SI. Methods should, as far as possible, be described briefly in appropriate table and figure legends.

Figures. In the case of line drawings one set of originals (without any lettering) is sufficient, with two copies containing lettering. In the case of photographs good prints are required with each copy of the manuscript; photocopies are not acceptable. Line drawings should be roughly twice the final printed size. The correct orientation should be indicated if not clear.

Photomicrographs and other photographs that require it must have a scale bar, which should be defined clearly in the legend. Primary data should be submitted as far as possible (e.g. actual photographs of electrophoretic gels rather than idealized diagrams).

References should be numbered in the order in which they appear, first through the text and then through table and figure legends. The following are examples of ways of writing references.

1. Mukundan, T. and Kishore, K., *Curr. Sci.*, 1991, **60**, 355-362.
2. Constantine, G., in *Biology of Bats* (ed. Wimsatt, W. A), Academic Press, New York, 1970, vol 1, pp. 319-322.

Acknowledgements should be brief. Footnotes are not allowed except to identify the corresponding author if not the first.

Cover photographs. Good photographs (colour or black and white) that pertain to a submitted paper will be considered for use on the cover. Good *prints* and a legend should be submitted with the manuscript. In the case of a colour picture, a transparency will be required for printing if accepted.

PROOFS AND PUBLICATION

Two sets of galley proofs are sent to the corresponding author. A reprint order form accompanies the proofs.

COVER. Lifescape of the earth: In this depiction relative sizes of organisms are proportional to the number of species in the different groups known to science. These include: Monera: 4800; Fungi: 69,000; Algae: 26,900; Higher plants: 248,000; Protozoa: 30,800; Porifera: 5000; Cnidaria and Ctenophora: 9000; Platyhelminthes: 12,200; Nematoda: 12,000; Annelida: 12,000; Mollusca: 50,000; Echinodermata: 6100; Insecta < 751,000; Non-insectan arthropods: 123,400; Fishes and lower chordates: 18,800; Amphibians: 4200; Reptiles: 6300; Birds: 9000; Mammals: 4000. With 2.2% of the landscape and 0.6% of the seascape, India harbours 7.5% of the known diversity of the earth's lifescape. [Watercolour by Sanjeeva Nayaka.] See page 688.

In this issue

Sálim Ali and the project 'Lifescape'

A special section is included in this issue of *Current Science* to mark the occasion of the birth centenary of the late Dr Sálim Ali – ornithologist extraordinary, naturalist par excellence, a great popularizer of natural history, a most inspiring teacher.

The project 'Lifescape', launched by the Indian Academy of Sciences to celebrate the birth centenary of Dr Sálim Ali, has been described by Madhav Gadgil on page 688. To begin with, this project plans to publish illustrated accounts of 2500–5000 species of living organisms – from the lowly viruses, bacteria, algae, fungi, through mites, insects, spiders and ferns, up to reptiles, birds, mammals and trees – found in the different parts of India. This exercise, even by itself, would be a fitting tribute to the memory of Dr Sálim Ali, who had remarked that 'the absence of illustrated books was, in my opinion, the most serious obstacle to the development of bird-watching'. Though Dr Sálim Ali completely demolished this obstacle by writing a series of outstanding books as far as birds are concerned, the drawbacks continue to be serious for other, less glamorous creatures. Now, though some are certainly more equal, all living organisms are equal – especially in the light of the Rio summit and the Biodiversity Convention. Preparation of such illustrated accounts of different groups of living organisms is in fact a fundamental necessity for fulfilling our national mandate of inventorying and monitoring biodiversity. (Of course, this could, in the process, lead to the discovery of the locations of rare, endangered but commercially highly lu-

crative species – and thus possibly abet the violation of the third mandate of conserving biodiversity; but it is an acceptable risk.)

However, these illustrated accounts are also meant to be the thin end of the wedge, aimed at enhancing the quality of science education in the country, to begin with, by suitable alterations in the syllabi. It is well-known that the study of biology, from the school level right up to the post-graduate level, places great emphasis on the text-book/laboratory approach – to the almost exclusion of the living world around us (though there are welcome signs of change, especially with the rising importance of environmental science). Madhav Gadgil points out that studying the living should be at least as important as studying the dead (i.e. watching birds, counting butterflies and collecting seeds should be as important as dissecting frogs). Students would no doubt wholeheartedly embrace this point of view! In his autobiography *The Fall of a Sparrow*, Dr Sálim Ali describes how, as a schoolboy, 'watching the behaviour and actions of his pet birds for hours together gave immense joy ...' and 'found this to be a far more pleasant way of passing time than doing homework'. And the new syllabus proposed in the article makes sure that not just homework, but even classwork involves activities of this kind. (It is tempting to speculate if students are opposed to classwork/homework per se, regardless of the intrinsic merit or interest of the topic. Assuming that the new syllabus is implemented, would the students a few generations from now equally wholeheartedly welcome a change from this crazy pursuit of creepy-crawlies in slushy swamps in pouring rain to the air-conditioned

comforts of dissecting a frog on the computer screen, using the latest virtual-reality software obtained by surfing on the internet.)

But, coming back to the Lifescape project, curriculum development is just one of its objectives. The more important goal is the compilation of the invaluable information generated from such studies involving projects by school, college and university students. For a nation as vast and as richly diverse as India, it is impossible either for the government or for any other central agency to collect country-wide information on location, distribution, abundance, etc. even for species of great economic importance – pests, pollinators, disease vectors and the like. On the other hand, student projects bring in thousands (if not more) of highly enthusiastic and motivated volunteers, who for weeks together would cheerfully brave all hardships of working in inaccessible places at unearthly hours, and generate high-quality information, while educating themselves about many subdisciplines of biology in the process. The article also describes in depth the philosophical underpinnings, the national status and the logistic aspects of the project.

A tribute to Dr Sálim Ali by one of his close associates J. C. Daniels, reproduced on page 686 of this issue, brings out the continued reverence felt towards the 'Old Man' by his colleagues and students. Of particular relevance is the description of gravity and care exercised by Dr Sálim Ali in the handling of public funds, a trait extremely worthy of emulation. Daniels also brings out the sense of wonder evoked by the enormous amount of valuable scientific information generated by Dr Sálim Ali,

with little more paraphernalia than a notebook, a pencil and a pair of binoculars (but then there was his extremely alert and analytical mind).

A brief sketch highlighting the quintessential features of Sálím Ali, the scientist, by Madhav Gadgil (page 685) describes Sálím Ali as 'the greatest whole organism biologist of 20th Century India' – (Now the phrase 'whole-organism-biologist' is a curious one – making one wonder if it includes those who work on whole viruses, whole bacteria and the like, and conjures up images of 'whole-molecule chemists' and 'whole-membrane-biophysicists' scoffing

at the lesser mortals who work merely on the constituent parts). Beginning with the description of an important experiment conducted by Dr Sálím Ali when he was all of eleven years old, the article traces his scientific career from Burma to Berlin to Bombay Natural History Society. It is interesting that the Burma stint was triggered by the evils of mathematics (logarithms and higher algebra) being taught in the first year of college. Mathematics thus seems to have made singularly important (and alas, totally unrecognized) contributions to the study of the ecology of the birds of Burma. The write-up also emphasizes what a pleasurable

reading Dr Sálím Ali's books make.

Talking about the status of ornithology in India in the 1920–1930, Dr Sálím Ali had described it as the 'Cinderella of Indian Zoology'. As of 1996, this poor sister has been magically transformed into a princess (if not the queen). There can be no doubt that this magic spell was cast almost entirely by a single individual. In the words of R. E. Hawkins

William Shakespeare's a master of words
And a tusker a leader of herds
But wherever you fare
Over land, sea or air
Sálím Ali is the raja of birds.

N. V. Joshi

SUBMISSION IN ELECTRONIC FORM

Authors who have been informed of acceptance of their manuscripts may send the final version in electronic form on floppy diskette (3.5" preferred; IBM PC format only, *not* Macintosh). The text of the manuscript only should be supplied as a plain ASCII file with no formatting other than line and paragraph breaks. (Wordstar 5.5 or 7.0 and Microsoft Word for Windows 6.0 are acceptable, but ASCII is preferred.) A hard copy of the text, with all typesetting information (italics, bold, mathematical type, superscripts, subscripts, etc.) must accompany the electronic copy. Tables and figures must be supplied only as hard copy. The diskette must be labelled clearly with the following: manuscript number, file name, file information (ASCII or Wordstar, version number, etc.).

Text may also be transmitted as ASCII only by e-mail to currsci@ias.ernet.in.

We expect that electronic submission will result in quicker processing for publication.

CORRESPONDENCE

Gene therapy

The introductory puff piece on page 339 and the article itself (P. N. Rangarajan and G. Padmanaban, *Curr. Sci.*, 1996, 71, 360-368) on Gene Therapy seemed strangely anachronistic in 1996. The authors seem to be totally unaware that gene therapy like King Balshazzar has been weighed in the balance of actual practice and found wanting. The US National Institutes of Health, having funded this narrow field for a decade at about \$200 million per year conducted its own in-house evaluation. This 'Report and Recommendations of the Panel to Assess the NIH Investment in Research on Gene Therapy (December 7, 1995)' finds that in spite of the huge expenditures *not one human has been cured* by gene therapy (see page 658).

Quite a record. The cost to society per life saved so far is infinite. Even after your authors' 'light at the end of tunnel' appears, those costs will not come down much. Indeed such high-tech medicine aimed at a few patients, however heart-rending the stories, is a major cost driver in medicine today. It is also a major attention-diverter for the scientific community away from the enormous problems in preventive medicine which affect tens of thousands.

Today research funds are driven more by the number of researchers and their need to be kept busy in their subspecialties. That is a major part of the cause of the impending crash of the US health care system. As a science policy analyst I have been emphasizing to governments that the *only* way to contain runaway research costs is to allocate research funds by the potential benefits, in this case the number of persons affected, and the seriousness of the disability. Those of us paid from the public purse for our research

must very seriously ask whether the public has a reasonable chance of obtaining any return on its investment. Or have scientists become 'welfare queens in white coats' expecting to be supported for doing our research irrespective of the outcome.

Rangarajan and Padmanaban reply:

It is easy to be critical and cynical with information interpreted to one's own way of thinking. Every emerging area including molecular biology as a field and recombinant DNA as a technology have faced strident criticisms in terms of utility, before they were accepted as powerful tools not only in basic research but also in terms of applications. When the introduction of a single new drug into the market is estimated to take 15 years and in excess of \$300 million, we are surprised that gene therapy is expected to deliver on its promises within a decade of investment. The euphoria created on gene therapy due to public pressure, commercial interests and media hype is well known. We are quite aware of the NIH panel report, which has characterized NIH spending of \$200 million as 'appropriate', but has recommended instituting short-term grants to fund innovative research and to test new ideas (*Nature Medicine*,

1996, 2, 7-8). Another commentary states 'Human gene therapy has not yet come of age, but there can be no justification for doubting its eventual success, as an adjunct to traditional therapies or as a definitive therapy on its own. The most revolutionary aspect of human gene therapy has been the conceptual one and that phase is over. We have now reached the difficult evolutionary stage of making it work.' 'Human gene therapy is not yet ready for prime time at least at the clinical level. But it is ready for and needs prime time nurturing and development' (*Nature Medicine*, 1996, 2, 144-147). Hopefully, these will not be considered as anachronistic in 1996! The consensus is to 'go back to the basics' and fill in the missing links as discussed in our article. The fact remains that gene therapy offers hope of cure not only to genetic disorders, but also to cancers and infectious diseases. Infact, serendipity has led to the birth of DNA (genetic) vaccinations, a facet of gene therapy research that holds tremendous promise. One is not just thinking of unaffordable treatment to a few patients, but approaches based on direct DNA injection, genetic immunization, etc., that will be cost effective and benefit millions, especially in the developing world. Once again, there are hurdles to cross and these are worth crossing.

Professional science analysts and those who are in a position to advice governments should necessarily have a balanced view. It is easy to give populist advice such as to allocate research funds on the basis of potential benefits, number of persons affected, seriousness of disease, etc. Such advice will be lapped up by politicians but history is replete with instances of blue sky research, serendipity

CORRESPONDENCE

as well as goal-oriented research contributing to human welfare. While, governments in general should be helped to decide on priorities, gene therapy as such has tremendous possible applications for mankind and sweeping gener-

alities will only harm a great cause. Let us not straight jacket issues and make scientists appear as in 'white coats for self-preservation'. The community is as much interested in human welfare as any one else professing the same.

Report and recommendations of the panel to assess the NIH investment in research on gene therapy

Executive summary of findings and recommendations

Dr Harold Varmus, Director, National Institutes of Health (NIH), appointed an *ad hoc* committee* to assess the current status and promise of gene therapy and provide recommendations regarding future NIH-sponsored research in this area. The Panel was asked specifically to comment on how funds and efforts should be distributed among various research areas and what funding mechanisms would be most effective in meeting research goals.

The Panel finds that:

1. Somatic gene therapy is a logical and natural progression in the application of fundamental biomedical science to medicine and offers extraordinary potential, in the long-term, for the management and correction of human disease, including inherited and acquired disorders, cancer, and AIDS. The concept that gene transfer might be used to treat disease is founded on the remarkable advances of the past two decades in recombinant DNA technology. The types of diseases under consideration for gene therapy are diverse; hence, many different treatment strategies are being investigated, each with its own set of scientific and clinical challenges.
2. While the expectations and the promise of gene therapy are great, clinical efficacy has not been definitively demonstrated at this time in any gene

therapy protocol, despite anecdotal claims of successful therapy and the initiation of more than 100 Recombinant DNA Advisory Committee (RAC)-approved protocols.

3. Significant problems remain in all basic aspects of gene therapy. Major difficulties at the basic level include shortcomings in all current gene transfer vectors and an inadequate understanding of the biological interaction of these vectors with the host.
4. In the enthusiasm to proceed to clinical trials, basic studies of disease pathophysiology, which are likely to be critical to the eventual success of gene therapy, have not been given adequate attention. Such studies can lead to better definition of the important target cell(s) and to more effective design of the therapeutic approach. They often can be carried out in appropriate animal models. Pathophysiologic studies may also suggest alternative treatment strategies.
5. There is a clear and legitimate need for clinical studies to evaluate various aspects of gene therapy approaches. Although animal investigations are often valuable, it is not always possible to extrapolate directly from animal experiments to human studies. Indeed, in some cases, such as cystic fibrosis, cancer, and AIDS, animal models do not satisfactorily mimic the major manifestations of the corresponding human disease. Clinical studies represent not only practical implementation of basic discoveries, but also critical experiments which refine and define new questions to be addressed by non-clinical investigation.
6. Interpretation of the results of many gene therapy protocols has been hindered by a very low frequency of gene transfer, reliance on qualitative rather than quantitative assessments of gene transfer and expression, lack of suitable controls, and lack of rigorously defined biochemical or disease endpoints. The impression of the Panel is that only a minority of clinical studies, illustrated by some gene marking experiments, have been designed to yield useful basic information.
7. Overselling of the results of laboratory and clinical studies by investigators and their sponsors—be they academic, federal, or industrial—has led to the mistaken and widespread perception that gene therapy is further developed and more successful than it actually is. Such inaccurate portrayals threaten confidence in the integrity of the field and may ultimately hinder progress toward successful application of gene therapy to human disease.

Based on these findings, the Panel recommends the following:

1. In order to confront the major outstanding obstacles to successful somatic gene therapy, greater focus on basic aspects of gene transfer, and gene expression within the context of gene transfer approaches, is required. Such efforts need to be applied to improving vectors for gene delivery, enhancing and maintaining high level expression of genes transferred to somatic cells, achieving tissue-specific and regulated expression of transferred genes, and directing gene transfer to

*Stuart H. Orkin and Arno G. Motulsky, Co-chairs.

- specific cell types. To stimulate innovative research, the Panel recommends the use of interdisciplinary workshops, specific programme announcements in these areas, and the use of short-term, pilot grants for testing new ideas and for encouraging investigators from other areas to enter the field of gene therapy.
2. To address important biological questions and provide a basis for the discovery of alternative treatment modalities, the Panel recommends increased emphasis on research dealing with the mechanisms of disease pathogenesis, further development of animal models of disease, enhanced use of pre-clinical gene therapy approaches in these models, and greater study of stem cell biology in diverse organ systems.
 3. Strict adherence to high standards for excellence in clinical protocols must be demanded of investigators. Gene therapy protocols need to meet the same high standards required for all forms of translational (or clinical) research, whatever the enthusiasm for this (or any other) treatment approach.
 4. To enhance the overall level of research in this area, the Panel recommends that NIH support broad interdisciplinary post-doctoral training of M.D. and Ph.D. investigators at the interface of clinical

- and basic science. Mechanisms for physician training in this area might include use of career development awards based on a programme announcement in gene therapy.
5. Investigators in the field and their supporters need to be more restrained in their public discussion of findings, publications, and immediate prospects for the successful implementation of gene therapy approaches. The Panel recommends a concerted effort on the part of scientists, clinicians, science writers, research advocates, research institutions, industry, and the press to inform the public about not only the extraordinary promise of gene therapy, but also its current limitations.
 6. NIH has already provided an appropriate initial investment in gene therapy. Future gene therapy research should compete with other forms of biomedical research for funding under stringent peer review. Only with fair, yet critical, peer review will high standards be met and maintained. The Panel specifically does not recommend special gene therapy study sections, expansion of existing centre programmes in gene therapy, or expansion of the recently funded core vector production programme. To ensure that the level of support remains appropriate, the

NIH investment in this field should be reexamined periodically.

7. To enhance the contribution of industry to the field, the Panel recommends that NIH encourage collaborative arrangements between academic institutions and industry that complement NIH-supported research, and also implement mechanisms that facilitate the distribution and testing of vectors and adjunct materials for use in clinical studies.
8. In an effort to improve gene therapy research and reduce duplication of effort, the Panel urges better coordination and scientific review of such research throughout the NIH Intramural Programme. In addition, NIH Institute Directors should resist pressures to include gene therapy research in their portfolios (either intramural or extramural) to 'round out' their programmes or compete with other Institutes. Instead, they should include such research only when there are compelling scientific reasons to go forward. Institute Directors should take the lead, where it seems appropriate, to focus efforts on improvement of diagnosis and understanding of disease pathogenesis and await further developments in vector technology before expanding clinical gene therapy programmes.

Asteroids and Earth's evolution – A new perception

Shaking the very foundations of long-accepted geological and geophysical theories, some new unorthodox views which cannot be brushed aside have been put forward by H. R. Shaw, a researcher in the US Geological Survey, in his recent book *Craters, Cosmos and Chronicles: A New Theory of Earth* (Stanford University Press). Shaw feels that asteroids and comets had a much greater role in shaping Earth's geological evolution than has been presumed so far. These celestial bodies did not impact randomly all over Earth, but hit only particular spots, determined by their nonlinear interactions with members of the solar system. The repeated batterings that the Earth has taken in its long past have contributed to the various geophysical phenomena

like the distribution of continents, disposition of Earth's magnetic field, triggering of volcanic eruptions and the evolution and extinction of life forms.

Along with colleague William Glen, he chronicled several asteroid impacts between the time period 50–100 million years ago, and surprisingly found that their impact sites fell along a line encircling the globe, which they aptly called the K–T swath, after the famous asteroid impact during the Cretaceous–Tertiary period (Figure 1). Still older impact sites dating back to 600 million years ago were also found to group into three distinct clusters in North America, Eurasia and Australia, instead of being randomly distributed among all continents.

Shaw feels that chaos arising from

nonlinear interplanetary gravitational influences dictates the orbits assumed by asteroids which are believed to have been ejected out of the main asteroid belt. Their chaotic trajectories bring them into inner solar system, where they come within the grip of the Earth (or other inner planets) and once within its influence, the uneven distribution of mass inside the Earth causes the paths of these asteroids to shift gradually to specific orbits, in tune with the fluctuating gravity profile over the Earth. In due course, they end up crashing to the Earth, always along circular tracks corresponding to their gravity-tuned trajectories. According to Shaw, these bodies have been crashing along a limited array of sites or 'cratering nodes' over the past half-billion years.

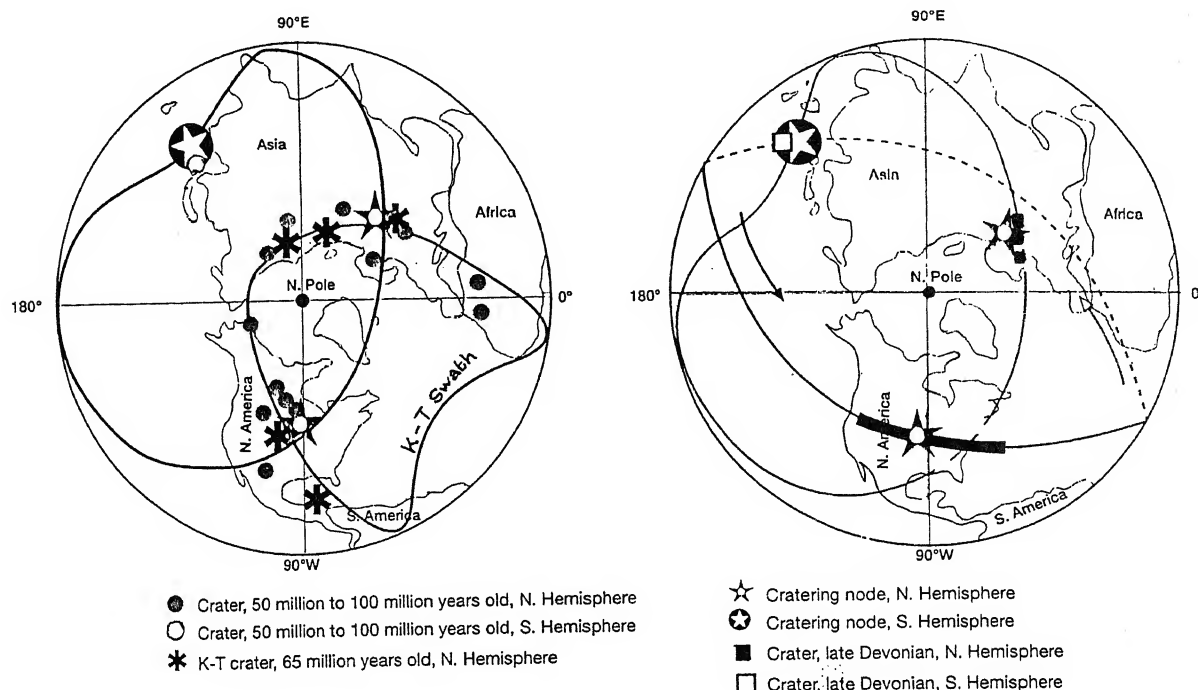

Figure 1.

After elaborate computer calculations, Shaw has derived a potential orbit for Earth-circling asteroids.

While the postulated mechanics of asteroid capture appear plausible, their role as prime agent shaping Earth opposes well-accepted theories. For example, Shaw feels that their powerful impacts in the past triggered some of the flood basalt eruptions which he finds located along the great circle. This runs counter to the accepted idea that they arise as plumes of hot lava from Earth's molten interior. Similarly, his hypothesis is

opposed to current theories of plate tectonics, or the drifting of continents. He finds that the regions frequently hit, i.e. the cratering nodes, have remained the same during the vast span of 600 million years, thereby implying that the continents have not drifted for long periods, or they did so, much less than what is believed, or they have been returning again and again to the same location. Even the well-documented shifting of the Earth's magnetic field, believed to be caused by drifting currents of molten iron within the Earth's core is attributed by Shaw to

powerful asteroid impacts inducing the drifts.

Although a few scientists in the past have linked asteroid impacts to the onset of volcanism and drifting of magnetic field, it is however Shaw who unified these by applying nonlinear dynamics and predicting patterns in their paths, otherwise not apparent.

The manganese hide out in the photosynthetic reaction centre

M. K. Raval

A manganese cluster oxidizes water to oxygen in the reaction centre II of oxygen evolving photosynthetic organism. This photochemical reaction is crucial for production of biomass and maintenance of

oxygen level on earth. Therefore, the study of structural and functional aspects of the Mn-centre has received much attention¹. Knowledge of structural organization of Mn and its ligands in the

catalytic centre and mechanism of photo-oxidation of water might lead to design of synthetic Mn-centre mimicking photosynthetic reaction centre II for harvesting solar energy². However, it has not been

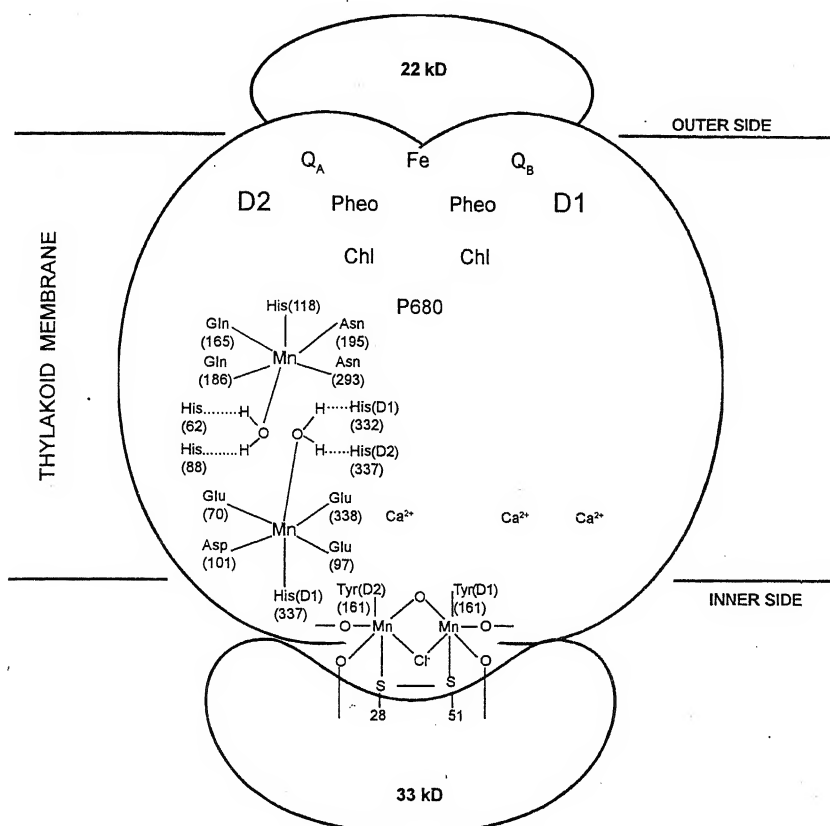

Figure 1. A model for structural organization of Mn in photosynthetic reaction centre II of higher plants⁹. D1, D2: heterodimeric proteins of reaction centre II; P680: Special pair Chlorophyll a absorbing at 680 nm; Chl: Chlorophyll a; Pheo: Pheophytin a; Q,A: Quinones A and B.

possible to discover the nature of this cluster (two dimers or a tetramer) as well as the hide out (amino acid residues ligating to Mn cluster) in the heterodimer proteins D1/D2, even after an untiring endeavour of almost two decades by scientists with elegant techniques like electron spin resonance (ESR)³ and extended X-ray absorption fine structure spectroscopy (EXAFS)⁴. X-ray crystal-

lographic structure determination of purple bacterial photosynthetic reaction centre and its similarity with oxygen evolving reaction centre II, inspired building of a number of models for the catalytic site of reaction centre II.

Recently, site-directed mutagenesis has shown promise to locate the manganese hide out. Debus and colleagues have reported some amino acid residues as

probable ligands to Mn through mutant study in cyanobacteria^{5,6}. The probable Mn binding ligands are H332, E333 and H337 of D1 protein. Earlier in 1990 Vermaas *et al.*⁷ had reported probability of E69 of D2 protein in cyanobacteria (E70 of D2 in higher plants)⁷. These results coincide with theoretical propositions made earlier. We had reported in 1990 in a theoretical model of reaction centre II, H332, H337 of D1 and E70 of D2 as ligands to Mn (Figure 1)⁸. The theoretical model of Coleman and Govindjee also proposes E70 of D2 and E333 of D1 to be possible Mn ligands⁹.

Though cumbersome the site-directed mutagenesis appears to be the only effective technique next to X-ray crystallography to discover the Mn hide out.

Giant magnetoresistance: New concepts

Magnetic coupling has played a key role in the discovery of the Giant Magnetoresistance (GMR) effect in thin films. In certain multilayers consisting of alternating ferro- and non-ferromagnetic films

(e.g. Co/Cu), adjacent ferromagnetic films couple to each other through the nonferromagnetic film separating them. When an external magnetic field is applied to overcome this coupling, the ferromagnetic moments align and as a result, a change in the electrical resistance of an unprecedented magnitude is observed. This is referred to as Giant Magnetoresistance or GMR effect.

The large drop in electrical resistance of a solid in a magnetic field is an important phenomenon that has a potential application in magnetic storage media like magneto-optical recording and magnetic sensing devices. Lanthanide manganites doped with alkaline earth metals like calcium or strontium having the formula $\text{La}_{1-x}\text{A}_x\text{MnO}_3$, (A = Ca, Sr) exhibit a

perovskite structure. Such oxides also exhibit a spectacular magnetoresistance effect and suppress the resistance in magnetic field of ~ 6 Tesla to $\sim 100\%$ at room temperature. While its utility is yet to be exploited commercially, at the fundamental level, the underlying cause of GMR effect has to be understood.

Among the hypotheses put forth so far by experts in this field, one hypothesis believes that the crucial cause of GMR is the so-called double-exchange (DE) phenomenon which involves the hopping of electrons between heterovalent $\text{Mn}^{3+}/\text{Mn}^{4+}$ pairs in the lanthanide oxide. Additionally, a strong Jahn-Teller distortion associated with the octahedrally coordinated $\text{Mn}^{3+} : 3d^4$ experienced in these materials also contributes to GMR.

An interesting development is the discovery of the GMR effect in another manganese oxide ($\text{Ti}_2\text{Mn}_2\text{O}_7$) which exhibits an entirely different type structure (the 'pyrochlore structure'). A recent paper in *Science* by Subramanian *et al.* (1996, 273, 81) has established that the GMR effect caused by this oxide is due to neither of the two earlier effects noticed among the earlier oxides. This new oxide is actually a stoichiometric compound having no mixed valency that is characteristic of the $\text{Mn}^{3+}/\text{Mn}^{4+}$ group. It has been postulated that magnetic ordering driven by superexchange and a strong spin-fluctuation scattering above the Curie temperature are the causes of GMR in this oxide. In addition, thallium(III) has also been implicated to have a role in GMR, as it tends to complicate the electronic structure by its own mixed valency ($\text{Ti}^{\text{I}}/\text{Ti}^{\text{III}}$). This role has already been well-established in thallium cuprate superconductors.

J. Gopalakrishnan

Once upon a (Jurassic) time...

Was the Archaeopteryx really the 'early bird'? For that matter, during the course of evolution, did crocodiles ever go vegetarian? Recently, old skeletons that have tumbled out from the lands of the Far east have provided several interesting answers to these queries. Avian fossils from

the Liaoning province in Northern China have thrown light on the existence of a new fossil bird, about the size of a pigeon, that is reverently referred to as *Confuciusornis sanctus* (Lian-Hai Hou *et al.*, *Nature*, 1995, 377, 616). Its external features bear the resemblance of both the modern birds (in the Cretaceous times) as well as the bird that existed during the earlier period (viz. the Archaeopteryx). These discoveries are considered to be very exciting in as much as they have questioned the existing views of Archaeopteryx ancestry to modern birds. Evidence now points out to a possibility of the existence of other side branches to the Avian tree. While the Archaeopteryx may also be one such branch, it had somehow met with a dead end. These findings lead to the obvious conclusion that if birds were already diverse in the Jurassic period, the still more primitive of the species must have taken to wings as early as the late Triassic—some 60 million years before Archaeopteryx even flapped its own, in the Jurassic skies.

Three decades ago, Chinese geologists surveying for petroleum in the Hui province of Central China stumbled upon a fossil of a strange animal that probably existed 120 million years ago. The fossil that found a home in Toronto museum was recently re-examined and has been identified as belonging to the crocodile family (Xiao-Chun Wu *et al.*, *Nature*, 1995, 376, 678). The reptile, called *Chimeraesuchus paradoxus*, showed a variation in its skeletal features to other crocodiles. The most striking difference was that unlike the sharp conical teeth characteristic of carnivorous crocodiles, this reptile had multicuspid molar teeth which strongly indicated that the latter was actually herbivorous. This was obviously the period of the 'green (r)evolution'!

A. V. Sankaran

Small is beautiful

One of the objectives in the study of materials today is the synthesis and design of matter at a nanometer scale. Patterning material at this scale is helpful in the manufacture of miniature electronic components. In 1856, Michael Faraday had observed that material properties are

strongly size-dependent and thus can actually be tuned to sensitivity.

Earlier approaches towards the preparation of coupled quantum dots included the co-colloids of cadmium selenide-zinc oxide and cadmium sulphide-silver iodide. Aggregates of gold could also be synthesized using small molecule cross-linking agents. While the properties of nanocrystals have been studied earlier using organic monolayers and crystallization, it was not known whether self-assembly methods could be employed to generate complex nanocrystals.

Molecules in biological systems are held together several types of bonds including the strong covalent force as well as the weaker hydrogen bonds. Due to the complex nature of recognition systems that exist in biological organisms, it becomes necessary for such bonds to be specific and precise. Can biological molecules be exploited in the design of nanostructures?

Paul A. Alivisatos and his colleagues at the University of California at Berkeley, USA have addressed this question in an elegant manner (as reported in *Nature*, 1996, 382, 609–611). Small stretches of DNA (oligonucleotides) were modified at their ends with sulphhydryl groups. These were then coupled with an excess of mono-maleimido-gold particles. Following this coupling, the oligo-gold conjugates were then combined with set amounts of complementary single-stranded oligos. The resulting double-stranded complexes were then purified and analysed both with biochemical methods as well as through direct observation using transmission electron microscopy.

Results demonstrate that the use of oligonucleotides in the synthesis of nanoparticles has great potential. For one thing, by altering the base composition of the oligonucleotide, it is possible to generate flexibility in the oligo structure. Due to the nature of bonds that exist in DNA, it is possible to reverse reaction using heat, unlike the situation that exists when organic synthetic methods are used. With the further improvement in the methodology like the use of shorter and more rigid linkers and the use of other ligands apart from gold, a wider range of physical phenomena can be investigated in nanostructure architecture. For the present, one can but admire the 'gold zari' made out of Nature's own exquisitely beautiful threads of DNA.

Turmeric – the golden spice

The dictionary defines 'turmeric' as an aromatic rhizome of an East Indian zingiberaceous plant, *Curcuma longa*. Curcumin (diferuloylmethane) is the yellow pigment in turmeric used as a spice, food coloring and as a preservative. The powder of the plant is used often as a condiment as in curry powder or as a yellow dye or as a medicine. Over the recent months, this plant has received much attention due to the challenge of the patent filed by a university overseas for the discovery of its wound-healing properties. Organizations in India maintain that this property has been very well-established in India and is not a novel finding in itself. While the debate is proceeding at a leisurely pace one could look at the actual scientific facts on this herb that have been established over the years in the scientific literature. A medline search revealed many interesting reports. Here are few published reports on the biochemistry of turmeric.

Peroxidation of lipids in the living body is known to destroy the cell membrane and ultimately lead to the premature ageing of an individual. Last year, a report on the isolation of the turmeric anti-oxidant protein (TAP) was isolated from an aqueous extract of turmeric (Selvam *et al.*, *J. Ethnopharmacol.*, 1995). This

protein was shown to inhibit unwanted lipid peroxidation in the rat system.

In September 1995, *Cancer Letters* reported a study conducted at the Rutgers State University of New Jersey. During chronic inflammation, chemicals called cytokines are released in the human body that in turn induce the release of nitric oxide. This causes considerable damage to DNA and can even lead to carcinogenesis. This study concentrated on the effect of curcumin (the active principle of turmeric) on inflammation. It was found that curcumin inhibited the nitrite production in mouse peritoneal cells to an extent of 75%. Turmeric was implicated to be an anti-inflammatory as well as an anti-cancer causing agent.

Compounds like eicosanoids can cause the aggregation of platelets that ultimately leads to inflammation at the site of the wound. A study carried out in Denmark by Srivastava and his colleagues (*Prostaglandins Leukot Essent Fatty Acids*, April 1995) revealed that turmeric inhibits the platelet aggregation by modulating the eicosanoid biosynthesis. This could pave the way for the development of drugs that block key enzymes involved in the eicosanoid biosynthesis.

At the National Cancer Institute, Maryland, the effect of turmeric on HIV infection was studied by Mazumdar and

his colleagues (*Biochem. Pharmacol.*, April 1995). Clinical trials in AIDS patients have revealed that turmeric actually blocks the functioning of the HIV integrase enzyme (of HIV type 1) that is required for the pathogenesis of the disease. Inhibition of an integrase deletion mutant containing only amino acids 50–212 suggests that curcumin interacts with the integrase catalytic core. This data suggests that HIV integrase inhibition could contribute to the antiviral activity of curcumin, giving hope to the development of new strategies for antiviral drug development that could be based on curcumin.

Several other interesting findings have been catalogued in the databank available on the wonderful uses of this exquisite herb. In essence, it would do one well to garnish generously the rasams, sambars and all that comprises the spicy Indian cuisine with more than a dash of this golden spice.

The patents that have so far been filed for its uses are numerous over the last couple of years. The recent patent list from the databank records a variety of findings that range from the use of turmeric as a dye to its use in the detection of cyanide adulterated food products. However, that is an entirely different story altogether.

SCIENTIFIC CORRESPONDENCE

Comments on 'The end phase of sedimentation of Krol Belt succession in Nainital syncline – Stratigraphic analysis and fossil levels' (D. K. Bhatt, *Curr. Sci.*, 1996, 70, 772–774)

The propositions of the author that 'both in terms of lithofacies and chronostratigraphy, the presence of Tal sequence in Nainital and the reported Ediacaran fossils from Nainital do not fulfil basic palaeontological requirements to be acceptable', are strongly refuted as they are not based on basic observable facts in the field. The following discussions would justify our points.

Detailed lithostratigraphic correlation and basin analysis based on lithofacies isopach maps of Blaini–Krol–Tal

sequence between Solan and Nainital^{1–4} have clearly demonstrated that the Tal Formation pinches southeast to Rikhnikhali in the Garhwal syncline and does not continue in Nainital area. The arenaceous beds in the form of rhythmite as well as thin quartz arenite bands exposed in the core of the Nainital syncline start appearing even in the upper part of the Krol sequence in the southeastern closure of the Garhwal syncline. This rhythmite horizon, which yields Ediacaran fossils in Nainital^{5,6}, Garhwal, Mussoorie and

Nigalidhar synclines^{4,7} belongs to the Upper Krol Formation (Krol-D) and not to the Tal Formation^{8–10}, which is well exposed in the Garhwal, Mussoorie, Korgai and Nigalidhar synclines^{1–3} and yielded characteristic fossil assemblages of Meishucunian to Tsanglangpuian stages^{11–17} of early Cambrian age, overlies the Ediacaran fossil yielding Krol Formation^{4,7}. The Ediacaran fossiliferous horizon in the upper part of Krol Formation (Krol-D) is characterized by $\delta^{13}\text{C}$ values that vary from 1.3 to 1.5‰ PDB in the

SCIENTIFIC CORRESPONDENCE

Garhwal syncline^{18,19}. Similar isotopic signatures have been described from other Ediacaran fossiliferous horizons in the world²⁰.

The horizon from which Ediacaran fossils were recorded, occurs near the top of the Krol-D sequence exposed in the core part of the Nainital syncline⁴⁻⁶. The level from which so-called 'chert-phosphorite Member of Tal Formation fauna' comprising *Coleoloides typicalis* Walcott and *Olivoides multisulcatus* Qian recorded by Bhatt and Mathur¹⁰, is stratigraphically well below the level from which we recorded Ediacaran fossils^{5,6}. The law of superimposition of strata does not permit beds with younger fauna to be underlying beds with older fauna unless the sequence is inverted, which certainly not is the case in Nainital Syncline. It is, therefore, clear that the beds from which fauna is described by Bhatt and Mathur¹⁰, is well within the Krol Formation (Krol-D).

Lucknow 226 024, India

D. K. Bhatt replies:

The disagreement of views pointed out by Shanker and Mathur relates not so much as to the observable facts in the field, but to the interpretation of the field observations, so far as the development of the Krol-Tal stratigraphy in the Nainital area is concerned. A host of recent workers on the basis of regional field observations¹ and/or detailed field work²⁻⁴ have demonstrated that not only the entire succession of the Krol Formation up to the level or Krol-E is present in the Nainital syncline, but also the additional strata described as Krol-F⁴ or Tal². This inference is supported by the recent record of small shelly fossils⁵.

The delineation of the extent of lithostratigraphic units within Proterozoic basins, having thousands of metre thick stratigraphic development and spanning

hundreds of million years, cannot be and should not be based solely upon 'lithofacies isopach maps'. So far as I am aware there exists no parallel example anywhere in the world where similar practice has been followed for determining the lithostratigraphic succession of a Proterozoic basin.

It may be reiterated that the topmost 75-80 m of the Krol Formation and the overlying 75 m thick Giwalikhet Member of the Tal Formation in the section at Nainital have yielded elements of small Shelly fossils⁵ that characterize strata of Meishucunian age elsewhere in the Krol Belt^{6,7}. The 'Ediacaran fossils' of Shanker and Mathur come from Narainagar Member of the Tal Formation that forms the youngest lithounit within Tal, overlying the Giwalikhet Member, in the Nainital section. Thus the 'Ediacaran fossil' level of Shanker and Mathur marking the strata of 'Ediacaran age' lies some 150 m above the horizon, revealing the oldest record of small shelly fossils of Meishucunian age (see paper under discussion and Figure 4 in ref. 5). This becomes chronostratigraphically incompatible, for the simple reason that the Ediacaran age has to precede the Meishucunian age according to the global chronostratigraphic scale.

Association of transglutaminase-like antigen with cytoskeletal proteins

Almost simultaneously but independently two papers dealing with an unique association of transglutaminase (TGase) with that of intermediate filaments (IF) such as keratins¹ and vimentin², appeared. The evidence for the novel association of TGase with keratin (58 kDa) stems from biophysical and biochemical analyses of keratin filaments, which elicited a greater order of aggregation in the presence of divalent cation such as calcium. The addition of the chelator, i.e. EDTA abolished the calcium-mediated aggregation of the reconstituted keratin filaments (RKF). This implicates the exquisite specificity for calcium which functions as a cofactor for the enzyme. Addition of effectors such as cystine and histamine to the RKF resulted in a significant reduction in the TGase activity as well as kinetics of an order of aggregation. Further, Western blot obtained with polyclonal antibody against guinea pig liver TGase cross-reacts with the 58 kDa protein in the urea soluble fraction from rat vaginal epithelium. This suggests that the guinea pig liver tissue TGase and the 58 kDa keratin share a common epitope as indicated in the published work earlier¹.

In line with the above mentioned data, Trejo-Skalli *et al.*² mainly using immunobiological techniques, have demonstrated an association of TGase related antigen with another cytoskeleton protein widely present in the fibroblasts called vimentin. By using double label immunofluorescence antibodies to vimentin and GP2.1.2 (a monoclonal antibody raised against guinea pig liver TGase) the authors have demonstrated *in situ* that TGase-like antigen cross-react with vimentin-positive fibroblasts. After subculturing of the primary cultures, a proportional increase in the percentage of GP2.1.2 positive cells is evident. Colchicine treatment did not perturb this association, indicating that the association is very stable. Morphological observations are further supported by the findings of Western blot data where GP2.1.2 recognizes a 280 kDa protein complex of vimentin with TGase in the IF-enriched cytoskeletal preparation but does not cross-react only with vimentin per se. Further when this anti-

body was injected into the live dermal fibroblasts it eventually resulted in the collapse of the vimentin IF network.

What could be the physiological implication of association of TGase with cytoskeletal proteins? An analysis of the subcellular distribution of TGases may reveal clues regarding their mechanism of action. TGases encompass an array of biological functions and its diversity and specific expression in different types of cells are attributed to the physiological requirement of the cell. In recent years, there is an increasing interest in TGases because of their involvement in rendering post-translational modifications in a variety of tissues. Most notable is the cross-linking of proteins by Σ (τ -glutamyl)lysine which is a covalent cross-linkage and shows resistant to the treatment by any known enzyme so far and also by many denaturants^{3,4}.

Some of the other major functions of TGases include irreversible membrane stiffening of the erythrocyte, receptor-mediated endocytosis and regulation of cellular growth and its differentiation by tissue TGase⁵, formation of insoluble cornified envelopes in epidermal keratinocytes by epidermal TGase⁶, formation of vaginal plugs by prostrate TGase⁷, formation of insoluble fibrin clots catalysed by factor XIIIa⁸, and in wound healing the cross-linking of fibronectin to collagen is brought about by factor XIIIa, and nerve regenerating process observed in optic nerve by nerve TGase^{9,10} and apoptotic process by tissue TGase^{11,12}.

Several reports are available to demonstrate the association of IF with various kinases like calcium and cAMP independent and dependent kinases^{13,14}. Other cytoskeletal filamentous structures like microtubules and microfilaments also show an association with the glycolytic enzymes. This association permits localized enrichment of these enzymes for energy dependence and the cytoskeletal matrix interactions¹⁵. Earlier studies on HT29 or NC-N417 cells have demonstrated the association of a kinase such as PKC Σ and cytokeratin fractions¹⁶.

A functional role of these associated TGases has not yet been ascribed. We can hypothesize that depending upon the biological signal the cell receives the corresponding TGase which may be activated to elicit its transamidating function. A key observation in our data is the demonstration of the catalytic potential for the transamidating activity of the keratin fraction by its ability to incorporate labelled ¹⁴C-spermidine substrate. *In vitro* vimentin was found to serve as a substrate for TGase. In skin and in VEC the cross-linking of keratins results in the formation of N Σ (τ -glutamyl)lysine bridges which contribute to the stabilization of the filament network.

An indepth understanding of this association would not only unravel the molecular mechanism underlying the protein-protein interactions but also paves way in understanding the physiobiophysical significance of this association as their specific substrates are found among the constituent component of the IF network itself.

Role of animals in the spread of human ringworm disease in Madras

Dermatophytosis in animals is an important public health problem, since this disease is frequently transmitted directly or indirectly from domestic and wild animals to man by contact^{1,2}. Several workers have reported zoonotic ringworm disease of man from different parts of India³⁻⁵. Here we report the isolation of three strains of *Trichophyton mentagrophytes* from animals and their epidemiologic importance in human ringworm disease in Madras since such data is not available.

One lion cub, one Nilgiri langur, three lamas, and three camels in Arignar Anna Zoological Garden and 22 dogs (17 native breeds, 2 German Shepherds, 2 Doberman, 1 pomeranian), 11 cattle and 1 donkey calf in and around the city of Madras were screened. The animals were thoroughly examined for the presence of any lesion suggestive of ringworm with the help of a veterinary officer. The fur was then combed with a sterile tooth brush and then stabbed onto Sabouraud's dextrose agar plates with and without antibiotics (chloramphenicol 0.5 mg/ml, cyclohexamide 0.5 mg/ml). The plates were incubated for 6 weeks at 26°C. Identification was done based on colony morphology and microscopic characters of the fungus. Hair perforation test, urease test and pigment production in corn meal agar were also

performed. Mating experiment was done on the teleomorphic identity and mating type of the isolates using the method of Padhye and Carmichael⁶. All the three strains of *T. mentagrophytes* were crossed with *Arthroderma benhamiae* RV26778(+), RV26780(-), *Arthroderma benhamiae* (African race) RV30000(+), RV30001(-), *Arthroderma vanbreuseghemii* RV27960(+), RV27961(-) and *Arthroderma simii* RV54201(-), RV25472(+) respectively. Sterilized garden soil baited with sterilized horse and guinea pig hair was used for conducting mating experiment. The plates were incubated at 26°C for six weeks away from light. Teleomorphs and mating types were identified on the basis of the production of gymnothecia. Asci and ascospores were examined microscopically.

In the present study, we isolated three strains of *T. mentagrophytes*, one each from a lion cub and two dogs. No symptomatic lesions were observed in these animals suggesting that animals may act as carriers of dermatophytes. All the animal isolates of *T. mentagrophytes* and 6/70 clinical isolates of *T. mentagrophytes* isolated in our previous study produced gymnothecia with *A. vanbreuseghemii* (-) mating type and was identified as *A. vanbreuseghemii* (+) mating type. The six clinical isolates which were recovered from severe cases of tinea capitis in

children belonged to rural Madras. These children would have contracted the disease while playing with animals. The isolation of one strain of *T. mentagrophytes* from a lion cub suggests that wild animals also may harbour pathogenic dermatophytes. Though the number of animals screened in the present study was small, findings strongly suggest that animals may act as vectors of human ringworm disease, especially in rural areas.

Human influence on global climate

J. Srinivasan

The Intergovernmental Panel on Climate Change (IPCC) has released recently its second assessment report. This has been produced by the working group I and is called 'Climate Change 1995: The Science of Climate Change'¹. The first assessment was published in 1990 and provided an excellent overview of scientific knowledge related to climate change at that time. The most important conclusion of the second assessment is that the balance of evidence suggests a discernible human influence on global climate. This conclusion has been challenged by the fossil-fuel lobby while the environmental lobby feels that the above statement is too weak!

The major controversies in this report pertain to chapter 8 on 'Detection of Climate Change and Attribution of Causes'. In this chapter the pattern of climate change predicted by climate models (including the effect of greenhouse gases and anthropogenic sulphate aerosols) has been compared with the observed geographical, seasonal, and vertical patterns of atmospheric temperature change. There are many similarities between the patterns of observed and predicted temperature change in the northern hemisphere during the period 1963–1988 (see Figure 1). The patterns of observed and predicted temperature change are not similar in the southern hemisphere. One of the reasons for the large differences in the southern hemisphere could be the paucity of data in this region. Hence one cannot state beyond all reasonable doubt that human impact on global climate has been detected.

The most interesting aspect of the pattern analysis is the poor agreement between observations and model in the northern hemisphere if the effects of anthropogenic sulphate aerosols (from burning of fossil fuels) are excluded. Thus the most important conclusion of the second assessment of IPCC is the role of anthropogenic sulphate aerosols in cooling the atmosphere and thereby counteracting the warming by greenhouse gases. The optimists and the fos-

sil-fuel lobby may be delighted that the effect of burning fossil fuels causes both warming and cooling of the atmosphere. They may hope that these two effects may leave the earth's climate largely unchanged. This will not happen because the emission of sulphate aerosols from thermal power plants in the industrialized countries has decreased dramatically in the last decade on account of concerns related to local atmospheric pollution. If the developing countries decide to enforce their environmental pollution laws with regard to sulphate aerosols then there may be no cooling of the atmosphere. The residence time of sulphate aerosols is a few years while the residence time of greenhouse gas such as carbon dioxide can be hundreds of years. In addition, the cooling due to aerosols is confined to regions where it is emitted but that due to greenhouse gases emissions have a global impact. Hence one cannot hope for a neat cancellation of the impact of emission of greenhouse gases and aerosols by fossil fuels. Can we really trust the predictions of global warming made by the Climate Models? The answer to this question is not simple. The anthropogenic influence on global climate is small but cumulative. Hence the effect of anthropogenic emission of greenhouse gases will be seen unambiguously after hundred or two hundred years. The climate models can be tested by checking whether they reproduce the observed variation of global temperature after a volcanic eruption. In 1991, Mt Pinatubo volcanic eruption caused, for a short period, radiative changes in the atmosphere comparable (but of opposite sign) to the doubling of carbon dioxide in the atmosphere. The climate models were able to predict correctly the global cooling that occurred on account of the aerosols injected into the stratosphere by the Mt Pinatubo volcanic eruption. Hence one can have some confidence with regard to predictions made by climate models with regard to global temperature change. We cannot, however, have the same level of confidence with

regard to predictions of regional temperature or precipitation changes by climate models.

What will be the impact of global warming on account of carbon dioxide emissions by fossil fuels? The immediate impact of global warming will be a rise in sea levels. There could, however, be a large error in the prediction of sea level rise. The large error occurs because we do not know the contribution of Greenland ice sheet and Antarctic ice sheet in the sea level rise. A warmer climate will increase the melt rates at the margins in the Greenland ice sheet and cause an increase in sea level. On the other hand, a warmer climate will increase accumulation of snow (because of higher snow fall) in the Antarctic ice sheet and hence result in a fall in sea levels! A warmer ocean will, of course, cause the water in the ocean to expand but the net effect of expansion of sea water and the change in mass balance of ice sheets cannot be predicted accurately. Hence the IPCC report predicts that in the next hundred years the rise in the sea level can be anywhere between 13 cm and 94 cm. There could, however, be unpleasant surprises on account of the instability of the West Antarctic Ice Sheet (WAIS). This ice sheet rests on a bed well below sea level. The dynamics of WAIS is dominated by fast-flowing ice streams and their influence on the stability of the WAIS is still in dispute. The IPCC report concludes, however, that the likelihood of a major sea level rise by the year 2100 due to the collapse of WAIS is low.

In an eloquent article in *Nature*², Broecker has warned that unpleasant surprises may occur when the earth's atmosphere enters a phase space which it has not experienced during the last 160,000 years. Broecker has said: 'Earth's climate does not respond to forcing in a smooth and gradual manner. Rather it responds in sharp jumps which involve large scale reorganization of the Earth's system. If this reading of the natural record is correct, then we must consider the possibility that the main re-

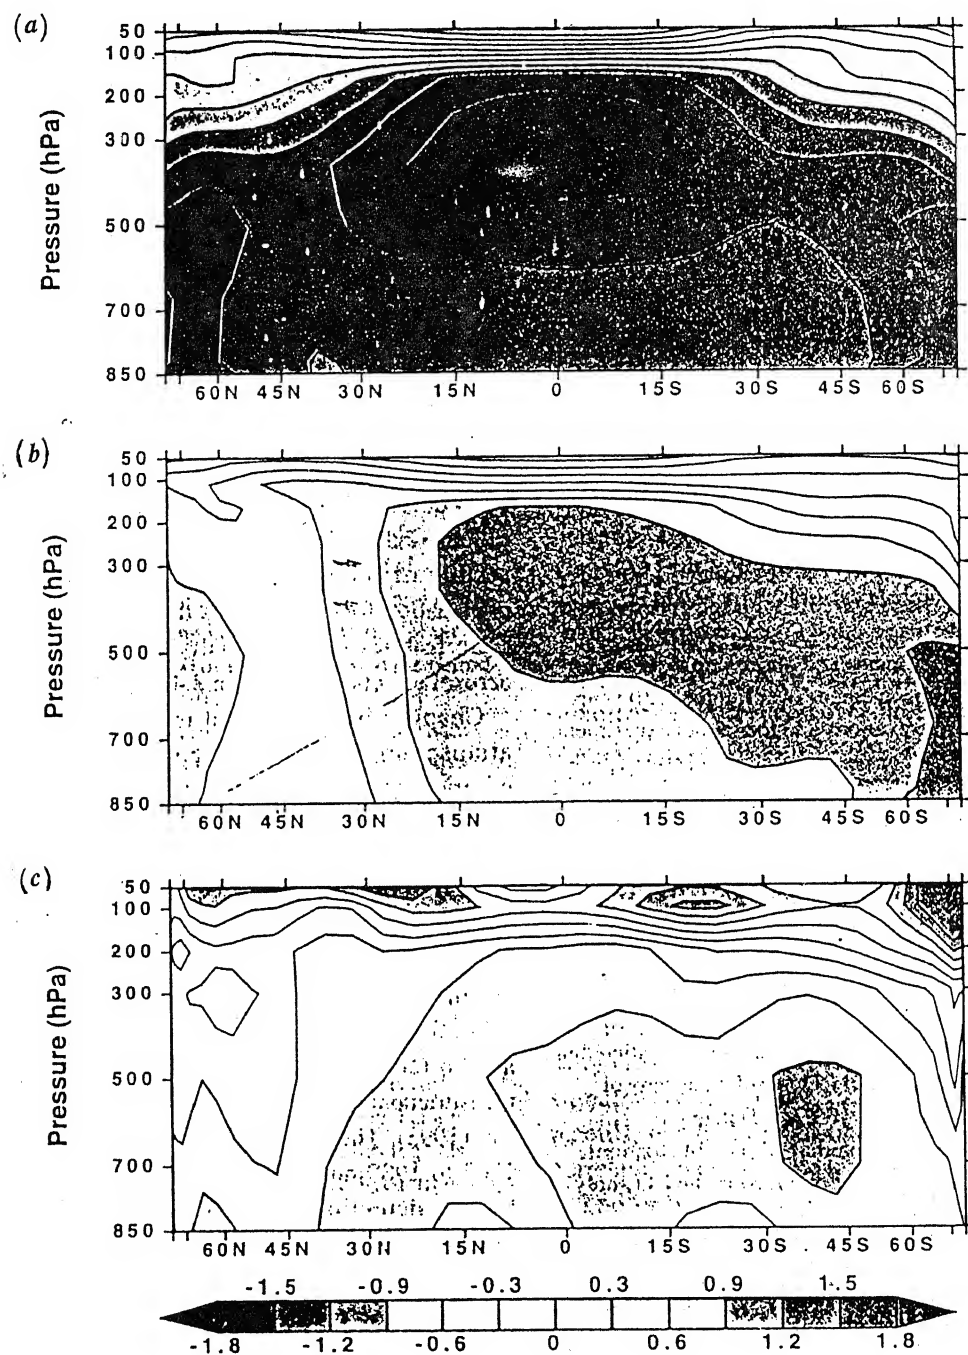

Figure 1 a–c. Modelled and observed changes in the zonal mean, annual-average temperature structure of the atmosphere. Model changes are expressed relative to a control run with pre-industrial levels of CO_2 and no anthropogenic sulphur emissions. The results obtained with present-day atmospheric concentration of CO_2 are shown in (a) and by the combined effect of present-day CO_2 levels and sulphur emissions are shown in (b), observed changes (c) are radiosonde-based temperature measurements and are expressed as total least-squares linear trends over the 25-year period from May 1963 to April 1988 (i.e. $^{\circ}\text{C}/25$ years). Figure from reference 1. For further details about the model refer to Santer, B. D. *et al.*, *Nature*, 1996, 382, 39–46.

sponse of the system to our provocation of the atmosphere will come in jumps whose timing and magnitude are unpredictable. Coping with this kind of change is clearly a far more serious matter than coping with gradual warming.' The warning with regard to unpleasant surprises should be taken seriously since the palaeoclimate record shows episodes of sudden cessation of the deep ocean circulation. There was an unpleasant surprise in 1980s when the 'Ozone hole' appeared over the Antarctic. Scientists had predicted the gradual depletion of ozone on account of the release of chloroflourocarbons (CFCs) by human beings. They were, however, unable to predict the rapid depletion of ozone that occurred in the Antarctic because the theoretical models used during that period had not incorporated the role of ice particles. The General Circulation Models (GCM) used to predict climate change are very complex and incorporate all known physical processes but one cannot rule out, for example, errors in the modelling of cloud physical processes or vegetation or uptake of carbon dioxide by the oceans.

The *Wall Street Journal* published an editorial on 12 June 1996, titled 'A Major Deception on Global Warming'. In this editorial, Fredrick Seitz (President emeritus of Rockefeller University and Chairman of the George C. Marshall Institute) has stated 'In my more than 60 years as a member of the American Scientific community, including service as president of both the National Academy of Sciences and the American Physical Society, I have never witnessed a more disturbing corruption of the peer-review process than the events that lead to this IPCC report'. He further states that nothing in the IPCC

rules permit anyone to change a scientific report after it has been accepted by the panel of scientific contributors and the full IPCC. The latter statement is not true and seems to be based on the ignorance of the rules governing IPCC reports. The first statement regarding the peer review process is unfair since the IPCC scientific report has been reviewed by more than 500 reviewers from 40 countries. As a lead author of Chapter 2 of the IPCC report 'Climate Change 1995', I was impressed by the seriousness with which every objection raised by the reviewers was discussed by the lead authors. The IPCC has made every attempt to incorporate diverse viewpoints without succumbing to the pressures exerted by various lobbies. The concern of the fossil-fuel lobby is understandable since they fear that this report may prod some countries to impose legislation that may lead to the reduction in the consumption of fossil fuels.

In view of all the uncertainty regarding the consequences of global warming, should we wait for some more time till we obtain unequivocal evidence regarding the deleterious consequences of global warming? This may mean that we may have to wait for another 50 years. The politicians and the fossil-fuel lobby will be very happy because we can postpone the unpleasant decisions to the future. The fossil-fuel lobby has been advocating this view. In the 1960s the tobacco-lobby argued that link between lung cancer and smoking was not demonstrated beyond reasonable doubt. In complex systems such as the human body or the earth it may not be possible to prove some hypothesis beyond any reasonable doubt. There could, however, be serious consequences if one

continues to smoke on the grounds that the relationship between smoking and cancer has not been proven beyond any reasonable doubt. Should we continue to burn fossil fuels because it provides us immediate benefits and not be concerned about the long-term consequences because there are uncertainties regarding the long-term effects?

The answer cannot be provided by scientists, economists, or politicians alone. In the final analysis, the answer depends upon one's attitude towards the natural world and the legacy we would like to leave for future generations. If the complex natural world is held in reverence, as most ancient people did, then one would be concerned about the irreversible changes that may be brought about by human beings. On the other hand, if one considers the natural world to be a resource to be exploited for the immediate benefit of human beings then there need be no concern for the future. In the next century, we have to strike a delicate balance between the necessity to exploit nature for the benefit of human beings and the responsibility to preserve the planet for future generations.

Biotechnology: Its global impact and relevance to India

Harish Padh

Biotechnology industry is maturing as an economic sector in the West. Approved products in the market, over 500 therapeutic products in the pipeline and renewed public confidence make it one of the most promising areas of economic growth in the near future. With liberalized economy, India offers a huge market for these products as well as cheap manufacturing base for export. However, for a variety of reasons, India has failed in developing these technologies for commercialization and the demand at the moment is met by imports. The proper technology licensing and transfer is suggested for immediate growth in this sector. Requirement of good infrastructure including a technopark is warranted in catalysing this growth.

BIOTECHNOLOGY encompasses aspects of biology, medicine, chemistry, and engineering. It has been defined by the US Government as '... any technique that uses living organisms (or parts of organisms) to make or modify products, to improve plants or animals, or to develop microorganisms for specific uses', in other words it is Applied Biology. Although the word biotechnology is new (around 1980), the science is not. Some examples of biotechnology used in ancient times, without knowledge of the underlying microbial processes, include beer fermentation by Babylonians (6000 BC), cheese making in Iraq (6000 BC), bread making by Egyptians (4000 BC). India can also take pride in contributing to the development of ancient biotechnology in the form of septic tanks in Mohenjodaro and Harappa regions (3000 BC). Four new technologies are responsible for bringing about the recent revolution in this field: viz. (i) Genetic engineering enabling us to identify and transfer genes from one organism to another, (ii) Cell fusion technology and resultant monoclonal antibodies, (iii) Bioprocess technologies to produce large quantities of important biological drugs, and (iv) Structure-based molecular design expediting new drug development. Various combinations and derivatives of these technologies are now available. The new biotechnology is a rapidly expanding collection of tools and technologies that allow, among other things, unprecedented control over and manipulation of the genetic material of organisms. In a short time, its impact is already visible, while its long-term potential is still unrealized at the moment. The book *Jurassic Park* by Michael Crichton and the movie by Steven Spielberg helped educate the general populace about the potential of genetic engineering.

Harish Padh is in the Department of Biochemistry, M.S. University of Baroda, Vadodara 390 002, India.

What can be done with these technologies?

Human body is a chemical factory running thousands of chemical reactions at a time. These reactions are catalysed by proteins which are made from respective genes. Therefore, a state of our body, healthy or otherwise, is determined by coordinated proper functioning of these proteins and genes. Recent advances have made it possible to isolate these genes and transfer them to another individual. In addition, biotechnology provides us ability to make rare but important proteins in abundant quantity. These advances have made it possible to use these genes and their protein products for therapeutic and diagnostic purposes. Unlike chemicals, these biologicals can be used for more effective treatment of various ailments, specially those for which there are no cures available at the moment. These possibilities also offer tremendous opportunities to improve agriculture products, animal stock, and to correct genetic disorders.

New biotechnology and its impact

The potential of biotechnology is responsible for bringing about the current revolution in biology. We now have in our grasp the means to produce large quantities of rare, medically valuable molecules, to modify plants and animals to carry specific hereditary traits, and novel means to detect disease, produce useful chemicals, and clean up and restore the environment. Thus, biotechnology has profound impact in the fields of health, food/agriculture and environmental protection. It has the potential to provide a wide array of benefits to humanity, including treatment for previously incurable diseases, healthier dairy and agricultural products, more resilient and productive crop plants and increased production of renewable sources of energy.

The US industrial sector now includes more than 1200 biotechnology start-up firms. More than 200 established companies, including many major chemical and pharmaceutical firms, have diversified into biotechnology. The distinction between biotechnological and pharmaceutical sector is fading because of the heavy involvement of pharmaceutical firms in biotechnology business. In little over a decade, this nascent industry has grown to be a multibillion dollar sector. By the end of the century this sector will match or surpass the computer industry in size, importance and growth.

Health care

Health care to-date has utilized biotechnology the most. The primary reasons are lack of good alternatives for treating the sick, dramatic results, big profits and good publicity. We still have many ailments for which we have no treatment or cure, for example, numerous genetic diseases, Alzheimer's disease, many types of cancer, hypertension, and AIDS. Biotechnology has allowed use of previously unavailable biologicals as medicines and made it possible to produce therapeutic biologicals in large quantities. Biologicals are our own molecules and are unlike chemical drugs. Biotechnology-derived proteins and polypeptides form the new class of potential drugs. For example insulin, used in the treatment of diabetes, was once primarily extracted from slaughtered animals. Since 1982, human insulin (Humulin®) has been produced by microorganisms in huge fermentation tanks. The global sales of Humulin® and other biotechnology drugs like Epogen® (Epoetin alfa from Amgen) and Recombivax HB® (Hepatitis B vaccine from Merck) have reached around US\$ 1 billion each. These products are convenient to make and more compatible with biological systems. In the recent past, the discovery of conventional drugs (heterocyclic chemical drugs including antibiotics) has slowed down. The number of biotechnology-derived new protein drug candidates has surpassed new chemical drugs since 1987 (see Figure 1).

At present there are about 35 biotechnology-derived

therapeutics and vaccines approved by the US FDA for medical use and over 500 additional drugs and vaccines by 150 companies are in various phases of clinical trials. Biotechnology has also spurred growth in diagnostics and over 600 biotechnology-based diagnostics are now available in clinical practice.

Gene therapy offers the potential to correct diseases at the genetic level. After creating scores of genetically modified plants and animals, human gene therapy looms on the horizon. The year 1995 marked significant developments in gene therapy. In USA there are about 130 approved gene therapy protocols. Half of these protocols are active with a total of about 600 patients under trials.

Agriculture

Although this area has benefited most from the ancient biotechnology, food/agriculture has been slow to utilize the modern advances in biotechnology. The reasons for this are numerous: a plentiful supply of food in the Western countries, the availability of other alternatives, apprehension over new technology, the complexity of plant and animal genomes, etc. The potential applications of biotechnology in foods and agriculture include better management of agro-ecosystems through decreased use of chemicals, increased use of pest and herbicide-resistant plants, new methods of maintaining soil productivity, better water management and new healthier foods with increased societal value. Functional foods (neutraceuticals) represent an active area of research to increase the nutritional value of foods, prevent diseases, and reduce healthcare costs. At present there are 14 or so sources of phytochemicals known to fight or retard malignancies. Biotechnology in the food/agriculture area is breaking new ground. Current public debate about BST (bovine somatotropin, a hormone administered to cows to increase milk production) typifies an example of a biotechnology product testing public acceptance. Similarly, the FlavrSavr™ tomato (produced by transgenic plants engineered by antisense technology to preserve flavour, texture and quality) is an example of a new breed of value-added foods. Food biotechnology offers valuable and perhaps the only viable alternative to food problems of developing countries. Food biotechnology also offers workable solutions to nutritionally influenced diseases like heart diseases, hypertension, arthritis, cancer, and diabetes.

Environment

Biotechnology products, like other 'high-tech' products, are inherently resource conserving, especially in comparison with older industrial methods of production.

Figure 1. Investigational new drugs: Biotechnology vs non-biotechnology.

GENERAL ARTICLES

Biotechnology offers additional environmental advantages when applied to current and emerging manufacturing processes. When applied to environmental issues, biotechnology is enhancing the pre-existing ability of nature to degrade compounds – disposing of wastes in a very *natural* way.

In March 1989, the oil supertanker Exxon Valdez lost 33 thousand tons of oil off the coast of Alaska at Prince Williams' Sound. For the first time, bioremediation technologies were employed in an actual oil spill to clean up crude oil contamination at the site of spillage. Several of the field tests were highly successful, with the added advantage that subsurface contamination (contamination below the surface of the soil or beach) was also remediated up to a depth of several feet.

Economic impact of biotechnology

Biotechnology companies develop technologies and products that expand the boundaries of medicine, agriculture, industrial processes and environmental science. They also build sustainable companies that bring new ways of competing and succeeding into traditional industries. The following are the highlights of biotechnology business in the USA. The European market is roughly of the same size as that of USA and no information is available for the market size in other continents.

General business highlights

- In Europe and USA, the sale for biotechnology-derived therapeutics is estimated to be 15 billion US dollars (Rs 52,500 crore). The sale of diagnostics is estimated to be another 15 billion US dollars. It is a multibillion dollar sector. Market size in the developing countries is not known. In USA, biotechnology has captured 10–15% of the total healthcare market.
- The sales, revenues, and equity in this sector are increasing with an annual rate of about 10–20% (Table 1). With many products in the pipeline and increasing public education and acceptance of biotechnology, the momentum will continue.
- Table 2 shows ten years history of biotechnology.
- It is a R&D-intensive sector (Table 1). At the moment, much of the revenues are poured back into R&D, compared to about 6% invested in R&D by US pharmaceutical sector and about 1% of sales invested in R&D by the Indian pharma sector.
- Total public equity raised is about \$1 billion a year (Figure 2). Some decline since 1992 has been reversed since 1995.
- Financing (raising capital) varies from year to year averaging about \$2 billion per year contributed almost equally by public offering, venture capital and private

Table 1. Highlights of biotechnology industries in USA (billion US\$)

	1995	1994	Per cent change
Sales	\$9.3	\$7.9	18%
Revenues	\$12.7	\$11.3	12%
R&D expenditure	\$7.7	\$7.1	8%
Market capitalization	\$52.0	\$41.0	27%
Number of companies	1,308	1,311	0%
Employees	108,000	103,000	5%

Table 2. Ten-year history of the biotechnology therapeutics in USA

	1985	1990	1995
Sales (\$ in billion)	\$1.1	\$2.9	\$9.3
Revenues (\$ in billion)	\$2.2	\$4.7	\$12.7
R&D expenditure (\$ in billion)	\$1.7	\$2.6	\$7.7
Number of companies	850	1,107	1,308
Employees	40,000	66,000	108,000

Figure 2. Biotechnology financing.

placement. Total money raised in 1995 through venture, private placements, initial public offerings and followups and strategic alliance was about 3.5 billion US Dollars.

- Agriculture biotechnology is expanding with a total market value of \$600 million with Calgene, which introduced FlavServ tomato, leading the market with \$200 million.
- Many genetically modified plants and plant products have obtained 'deregulated' status in USA and Europe, meaning no special approval necessary from FDA or USDA.
- The Biotech Equity Index (by Coopers and Lybrand, CLBI) has done better or as good as Standard & Poor 500 (broad-based equity index) over the period of time.
- Figure 1 shows that most of the new drugs coming to the market are biologicals manufactured by biotechnology.
- Biotechnology is entrepreneurial in nature. Over 90% of the biotech companies are small or medium size.

The larger companies are now entering the area by merger and acquisition.

- In later half of 1995, the stock market has come around for this sector and biotechnology is viewed as a promising area.
- Recently, European countries in general and Germany in particular have become receptive to biotechnology.
- Global market for industrial enzymes was about 1825 million US \$ in 1995 (Table 3) and increases about 20% a year.
- Top ten biotechnology companies are: Amgen, Genentech, Chiron, ALZA, Biogen, Genzyme, Genetics Institute, Centocor, IDEXX, Immunex.

Healthcare sector – Business highlights

- The Healthcare sector has so far benefited the most out of biotechnology. The Agriculture and Environment sectors are picking up. Among healthcare companies, therapeutic is followed by diagnostic.
- There are about 35 biotechnologically-derived therapeutics in the market in USA and Europe. About 500 more products by 158 companies are in human clinical trials. Many of these products will be in the market in coming years (Table 4).
- Human Genome Project, a mammoth undertaking to get a complete blueprint of human genetic material,

Table 3. Global market for industrial enzymes

User industry	1995, US\$ in millions
Detergent	710
Starch	220
Textile	245
Others	650
Total	1825

Table 4. Biotechnology pipeline

Status in clinical trial	Phase I	Phase II	Phase III	Approved
No. of therapeutic products	144	205	127	33

is viewed with tremendous potential for future products. Many established pharma companies paid handsome price for biotech firms with expertise, technologies or products from this project.

- There are over 600 new biotechnology-based diagnostics approved for use. Most of them are based on monoclonal antibodies (Table 5).
- Table 6 lists major biological therapeutics in use. Their sales are multibillion dollars each.
- Table 7 lists some of the recently approved biological therapeutics.

Agriculture and environment sectors – Business highlights

- Some of the applications of biotechnology in agriculture are in biopesticides, animal growth hormones, genetically modified plants and animals, animal and food diagnostics, animal vaccines, etc.
- *Pharming* is a new concept where therapeutic drugs are produced in the farm animals. For example, therapeutic proteins secreted in goat milk. There are about half a dozen companies specializing in this technology to make products like lactoferrin, tPA, hemoglobin, melanin and interleukines in cows, goats and pigs.
- Biopesticides are coming to the market and their sales are increasing.
- Bioremediation, which is environmentally friendly approach to clean the environment, is projected to reach global sales worth of 1 billion US \$ by the year 2000.

Future prospects for biotechnology industry

The biotech industry is just coming out of its infancy. Its potential is being tested, realized and used. The public awareness and acceptance will accelerate the process. This sector is expected to expand at least 3-fold by the end of the century and will match or surpass the computer industry in size, importance and growth (Table 8). It holds a good promise in a number of areas, specially those for which presently we have no treatment. There is tremendous potential for developing countries like India to apply biotechnology for agriculture and environmental resources.

Table 5. Approved biotech diagnostics

Type	Infectious disease	Tumour marker	Analyte and drug	Blood screening	Total
Monoclonal antibody	127	2	433	9	571
DNA probe	42	0	11	0	55
Recombinant DNA	11	1	1	0	13
Total	180	3	445	9	637

Biotechnology in India

- India has a number of good academic institutions with expertise in basic sciences relevant to biotech-

nology. India also has a fair number of suppliers and stockists who market required reagents and supplies. Assuming that the academic-industry interaction will improve, India is poised to explore biotechnology for business.

- Their is a surge in testing facilities, technology transfer, R&D institutions, small equipment fabricators, repackers and sellers of imported materials, etc.
- Proliferating private medical care and its importance in creating demand for biotech products.
- Catching up with the Western way of healthcare.
- India has rapidly swelling population of upper and middle class which has created unmet demand for newer diagnostics and therapeutics.
- Proliferation of diagnostics – mostly imported.
- General failure of diagnostics (imported as well as locally developed).
- Pharmaceutical industry in India is very strong and vibrant with expertise for chemical drugs. It has little experience in biotech diagnostics and no experience in biotech therapeutics.
- India is competing well in bulk drug production market. This is largely due to the more efficient nature of the processes and manufacturing costs. The same can hold true for the biological drugs.
- India's economic liberalization and signing of GATT and DUNKEL Draft clears the way and need for significant R&D activities by pharmaceutical industry.
- Impending patent changes will make it necessary to either develop our own technology or obtain proper license from others.
- Globalization of economy and liberalization of our economy make this an appropriate time to seek outside licensing and technology transfer.
- R&D activity in pharmaceutical industry will surge but with no significant experience in biotech, the pharmaceutical industry will need help.
- Local problems (malaria, tuberculosis, etc.) have remained untouched by biotechnology either in India or overseas. These problems will need innovative approaches.
- Agriculture, seed technology and environment could benefit tremendously by use of biotechnology.
- Table 9 indicates various factors influencing growth in a particular segment of economy. For example, in USA the growth is driven by innovation while in Germany the growth is driven by capital investment and proper technology management. In places like Thailand (and India?) the factors like cheap labour or availability of raw materials, etc. can spur growth. In a place like India and China, sudden growth is evidenced simply because of the rapid opening of huge consumer market. These and other factors lead us to believe that India is poised to enter biotechnology market.

Table 9. Driving forces influencing industrial growth

Driving force	Precondition	Strategy	Example
Factor	Factor advantage	Low tech sectors	Thailand, India???
Investment	Mature user industry	Investment in getting foreign technology, joint government and private ventures	Germany
Innovation	Developed science base, mature industry base, venture capital	New companies led development	USA
Market base	Sudden opening of large consumer market	Careful import and promotion of proven technologies	India, China, Eastern Europe? Former Soviet countries

- Infusion of foreign technologies and collaboration has already taken place in other sectors of economy. It is now time for Biotech/Pharma sector to seek proven technologies from outside.
- Import of technology will be a necessity. Government should provide proper channel and infrastructure to the pharma industry. This will lead to value added better stable, tested and validated products in the market.
- Other governments, including Germany has government-supported agencies for technology identification and import.
- Pharma industry is located between Mumbai and Ahmedabad (90% of the drug production in India is in Gujarat and Maharashtra). There is no government institution or university in this region with expertise in this area to help pharma industry.
- State industrial development corporations (SIDCs) should get serious about this sector and promote this sector by providing infrastructure and expertise.

Indian pharma industry

Indian pharmaceutical industry, with an expertise in chemical drugs, has done excellent job in the recent past. Total pharmaceutical industry sales is estimated to be Rs 50 billion. India is competing well in bulk drug as well as formulation markets. This is largely due to the more efficient nature of the processes and reduced manufacturing costs. The same can hold true for the biological drugs once the industry enters into manufacturing of biologicals. Moreover, India's economic liberalization and signing of GATT and DUNKEL Draft clears the way and need for significant R&D activities by pharmaceutical industry. Therefore, for a variety of reasons, the Indian pharmaceutical industry will sooner or later enter in manufacturing of biotechnology-based diagnostics and therapeutics.

Western India (Gujarat, Maharashtra and Rajasthan)

with more than 50% of the registered pharmaceutical units accounts for 90% of pharmaceutical production. The region also accounts for more than 70% of import and export of the pharmaceuticals.

Diagnostics

Worldwide there are about 600 new biotechnology-based diagnostics in the market with a value of about 20 billion US\$. Many more are about to enter the market, the most prominent among these will be PCR-based diagnostics. In India the diagnostics sales are expected to be between Rs 1 billion and Rs 2 billion. India relies on imports for many of the immunodiagnostics kits. Many of the locally developed diagnostics have failed, while the imported diagnostics are either unsuitable or expensive.

Therapeutics

Expression of foreign genes in convenient prokaryotic cells and the large-scale production of gene products is now routine. These protein products could have applications as therapeutics, diagnostics, restriction enzymes or industrial enzymes. At present, there are about 35 biotechnology-derived therapeutics approved for human use in USA. The total market value of these products is about 50 billion US\$. About 150 companies have 490 more products in various stages of clinical trials and development. With increasing acceptability of biotech products, there will be about 200 biotechnology-derived therapeutics available in the market by the turn of the century. In 1987, the number of new drugs produced by biotechnology has overtaken investigational new drug (IND) produced by conventional means (chemical and antibiotic drugs). This is an indication of the trend that in future new therapeutics will be made by cellular factories through recombinant technologies.

In India, there is no locally manufactured recombinant

GENERAL ARTICLES

therapeutic product available in the market. Few imported biological therapeutic products are marketed in India, e.g. human insulin and streptokinase.

Need for licensing and transfer of technologies

We have witnessed that indigenously developed diagnostics have shown less than satisfactory performance in the market. The imported diagnostics are not suitable because they are expensive, not directed against local pathogenic strains, and with little or no quality and stability controls. In addition, the Indian pharmaceutical industry has little or no experience in modern diagnostics or biological therapeutics. Their approach of process improvisation that worked well for chemical drugs will not work in biotechnology-based diagnostics or therapeutics. In addition, the number of newer diagnostics in the international market every year is burgeoning. Therefore, the national interest is better served by a systematic approach in identifying and transferring and licensing of appropriate technologies.

In the international market, biotechnology drugs are very expensive. For example, Genentech's tPA is priced at about \$2,000 per injection and streptokinase is marketed at about \$200 per injection. A genetically engineered Factor VIII used in the treatment of hemophiliacs cost \$25,000 a year. The next generation of these products will have to be less expensive and more effective. India can provide inexpensive manufacturing base for Indian as well as export market. Imported therapeutics traded in India are exorbitantly priced (Rs 300 per dose of human insulin compared to Rs 65 per dose of traditional insulin) and about Rs 4000 per dose of streptokinase. What will be our strategy when in five years there will be over 200 therapeutics and vaccines available? Shall we still rely on imports?

Need for technology development

There are a few diagnostics developed in the country but overall performance has been dismal. There seems to be a gap of culture, communication or something between the academic and corporate worlds as a result of which the indigenous technologies have not been

developed. The products do not reach the market or fail in the market. For a long-term interest of the nation there is a need for local development of technologies, especially against tuberculosis and malaria.

Agriculture

India which can use biotechnology for agriculture and environment cleaning has not really begun to exploit biotechnology in these areas. We have not produced genetically altered plants or engineered microorganism for bioremediation. The only activity India has developed is in plant tissue culture and plant micropropagation. In this sector, entrepreneurs have by and large imported technologies from abroad (mostly northern European countries) with buy-back arrangement for exporting the plant products. Locally developed technologies have found very limited use in the market. Local demand for these products is also highly underdeveloped.

Summary

We have to stop relying on imports and think about local manufacturing of the products mentioned above. This can be best achieved by proper technology licensing and transfer. We should also focus on technology development for the diseases of the developing countries.

The non-organic theory of the genesis of petroleum

Samar Abbas

Recent advances in interdisciplinary fields as diverse as astrophysics, cosmogeophysics, nuclear geology, etc. have led to interesting developments in the non-organic theory of the genesis of petroleum. This theory, which holds that petroleum is of an abiogenic primordial origin, provides an explanation for certain features of petroleum geology that are hard to explain within the standard organic framework. If the non-organic theory is correct, then hydrocarbon reserves would be enormous and almost inexhaustible.

PETROLEUM is the foundation of the industrial civilization. It is from petroleum that the world obtains its chemicals, fuel for automobiles, engines, airplanes, etc. and its energy supply for its power stations. Empires have risen and fallen due to the annexation or loss of oil fields. Hence, the origin of petroleum and the assurance of future energy supplies is of the utmost importance if this world is to continue as it is. It is generally believed that currently recoverable crude oil reserves will be nearing exhaustion within a few decades. This estimate is based on the conventionally accepted (organic) theory of the origin of petroleum.

However it does not necessarily follow that this civilization will fall into darkness. The origin of petroleum still, despite the immense amount of research devoted to it, has more uncertainties concerning it than any other common natural substance¹.

There are two basic frameworks: the standard organic theory, and the non-organic theory. The former holds that petroleum is of an organic origin and is the currently favoured proposal. It predicts limited reserves worldwide; moreover Indian reserves are predicted as minimal. The latter maintains that it is of non-organic genesis, supposedly of primordial origin. On the basis of this theory, oil resources would be much larger than those predicted by the biogenic theory. India, oil-poor in the biogenic framework, is predicted to be oil-rich in the non-organic one.

Unfortunately the abiogenic theory and its implications are not well known. Moreover, both opposing sides have taken uncompromising, even fundamentalist views on occasions. There is hence a crucial need, especially for nations such as India, to objectively assess the situation and investigate the latter possibility more carefully; especially since, as we shall discuss below, the evidence

in favour of either candidate is inconclusive and the question still remains an open one.

The organic theory

Outline

The organic theory holds that the first stage of the genesis of petroleum involves plankton (single-celled organisms that float on the oceans). These die and gradually accumulate on the ocean floor. Other sediments start accumulating too, and after a few million years the plankton are buried under several km of sediment. The plankton, which have remained unoxidized, under the increased values of pressure and temperature, are now transformed into kerogen. Under favourable conditions of time and temperature this kerogen, after further burial and heating, is transformed, via cracking, into petroleum and natural gas. These then migrate towards the surface and end up either reaching it (and drying up to yield bitumen or tar) or being arrested on the way in traps (where, millions of years later, drillers of the present industrial age make their big strikes)².

Advantages

Traditionally, the following points have been considered as supporting the biological theory:

- (i) Since it is known that hydrocarbons can be produced by photosynthesis, it is natural to expect petroleum to be of an organic origin.
- (ii) Molecules thought to be of biological origin, e.g. porphyrins, isoprenoids, hopanoids, etc. were found in petroleum, thereby providing support for the organic theory.
- (iii) The organic carbon in plants is depleted in carbon-13 due to the process of photosynthesis. In dead organic

Samar Abbas is in the Department of Physics, Utkal University, Bhubaneswar 751 004, India, and for correspondence: Institute of Physics, Bhubaneswar 751 005, India.

material the C-13 is further depleted due to radioactive decay. Since it was found that most petroleum and natural gas showed the same depletion, it was viewed as a strong proof in favour of an organic origin.

(iv) Sediments are the most important host rocks yielding petroleum, i.e. the oil produced from oil wells is generally obtained from a porous sandstone deep below. Often sediments are associated with biological material that could have acted as a source of the petroleum.

(v) The existence of large quantities of oil shale from which a hydrocarbon mix similar to petroleum could be distilled was seen as a support in favour of an organic origin. This followed easily, since the oil shale was taken to be the kerogen source rock which, on sufficient burial, purportedly yielded petroleum.

Disadvantages

However the following observations go against the organic theory:

(i) The discovery that meteorites contain hydrocarbons came as a great blow to advantages no. (i) and (ii) of the organic theory. Porphyrins and isoprenoids have been found on meteorites³. In addition, the outer planets contain large amounts of hydrocarbon.

(ii) The concentration of oil in the Middle East implies that that region must have been exceptionally prolific in plant and animal life over long periods of the Earth's history. This is unlikely, since life tends to be more dispersed, even today.

(iii) The biological supports of optical activity and an odd-even effect disappear at low levels. There is a sharp cutoff to the effect of optical activity: petroleum in Philippi's study⁴ was found to be optically active if derived from a reservoir with a temperature below 66°C, but surprisingly petroleum from deeper levels of the same field did not exhibit the phenomenon of optical activity. Gold⁵ proposed that a certain bacteria ceases action above 66°C, but he unfortunately did not suggest any candidates.

(iv) Methane occurs in giant ocean rifts, in continental rifts and the lakes that occur nearby, e.g. dissolved in the waters of the East African Lake Kivu⁶, as methane hydrates in permafrost, in active volcanic and mud volcanic regions, as well as at great depths of more than 10 km as geopressed gas etc. A biological origin for this methane can be virtually ruled out.

In the light of these difficulties one should consider the other rival non-organic theories as serious possibilities. They forecast much larger oil reserves than previously imagined and that too in regions which, according to the organic theory should be devoid of all petroleum.

The non-organic theory

Historical development

The non-organic theory of the genesis of petroleum has a long history, dating back to the early days of the oil industry. Its development has led to the birth of a number of variants, the most important of which are outlined below:

Metal carbide theory. The founder of the non-organic theory was Mendeleev, the Russian chemist who proposed the modern version of the periodic table. In 1877, he wrote that the petroleum deposits of the world seem to be controlled more by large scale tectonic features than by the ages of sedimentary rocks⁷. To explain these observations he put forth the metal carbide theory. Many contemporary investigators, mostly Russian, supported Mendeleev's view.

In this model metal carbides deep within the earth reacted with water at high temperatures to form acetylene which subsequently condensed to form heavier hydrocarbons (as is readily formed in the lab). The following reaction

is still popular amongst some astronomers and certain Russian geologists as a major petroleum-forming possibility².

Nebular condensation theory. In 1980 Sokoloff proposed that 'bitumina', at that time meaning the whole range of hydrocarbons from petroleum to tar, precipitated as rain onto the newly forming earth from the original nebular matter from which the Solar System was formed. In modern terminology he simply suggested that petroleum originated from meteorites. Later, he claimed, this petroleum was ejected from the earth's interior into the surface sediments⁸. Recently this idea has been supported by Hoyle, who proposes that not only oil, but life itself has extra-terrestrial origins⁹.

Volcanic origin theory. This postulate involves outgassing of the mantle via volcanic activity¹⁰.

Earthquake outgassing. This theory proposes that outgassing occurs via deep faults, and that this is still occurring today. The detailed mechanism has a long history. Vernadsky propounded the notion that hydrocarbon compounds would be stable against dissociation and oxidation at great depths and would replace carbon dioxide as the chief carbon-bearing fluid. Kudryavtsev set forth the observations supporting what was later to be known as Kudryavtsev's rule (to be discussed shortly).

Gold^{5,11} has become the main proponent of the idea of a non-organic origin in the West. Due to his initiative, a hole was drilled into crystalline basement rock which Gold predicted should yield petroleum. Only noncommercial quantities of petroleum, if any, were found. Moreover most of Gold's colleagues were not convinced. However, recently a nearby hole did strike oil (see below). This is now the most commonly known variant.

However, since Western nations either possess or control much of the world's petroleum reserves, there is no incentive to innovate. Since the nonorganic theory predicts petroleum in much larger quantities and in areas hitherto considered unfavourable, it is petroleum-poor countries like India who stand most to gain. Hence, it is they who should take the risks of exploring the non-organic theory, both theoretically and experimentally.

These are the prime variants of the theory. From now on, the word 'non-organic theory' shall be taken to propound merely a primordial (i.e. dating from the birth of the Earth) origin of petroleum which has been migrating outwards from great depths of the Earth to form all hydrocarbon deposits from tar and tar sands to oil shale. The detailed mechanisms mentioned above shall not complicate the issue during the course of the following discussion.

Outline of the theory

The theory suggests that most of the hydrocarbons on earth are in fact primordial. Carbonaceous chondrites appear to have been the most abundant source rock during the formation of the earth. This type of meteorite contains a significant amount of hydrocarbons. As the earth formed, it would have acquired these hydrocarbons via accretion (bodies of roughly equal size clumping together through collisions), and later through meteorite impacts (including hydrocarbons formed by the reaction of meteoritic carbon with H_2 at high pressures and temperatures on impact). Then as the earth gradually cooled, a solid crust developed, while the interior remained liquid or semisolid. The volatile substances would be expelled from the interior. It is such gases that yielded, after biological modification, the present atmosphere. That hydrocarbons are being evolved from the inner parts of the earth is evident from the presence of mud volcanoes, flames seen during earthquakes, etc. On the way up, it is supposed, the oil (dissolved in methane) would be trapped in suitable formations creating the world's oil and gas, tar sands, oil shales, bitumen, mud volcanoes, etc.¹¹ Kropotkin and Valyaev¹² pointed out that the hydrocarbons, carried upwards by streams of compressed gases, would have two possible destinies: (i) In volcanic regions, they would be oxidised to carbon dioxide and water, and (ii) In 'cool' regions the hydrocarbons would form oil and gas reservoirs after con-

densation from the rising stream at levels possessing the requisite values of temperature and pressure.

Evidence in favour of the non-organic theory

Geographical location. The major oil fields of the world are concentrated on or near belts of major tectonic activity or in fact along fault zones. Some of the phenomenal Arabian fields, the world's largest petroleum province, lie along the Persian Zagros Mt. belt. The large North Sea reserves that have made much of Northern Europe self-sufficient in oil production lie along the North Sea trench. The oil fields of Indonesia and Burma closely follow the seismic belt running from New Guinea to Burma, while the oil fields of Gujarat appear to be associated with the Cambay fault. Hydrocarbons are found in the Red Sea rift Valley, the East African rift and the eastern branch of the Pacific rift. These and many other examples that exist should illustrate the association of hydrocarbons with large deep-seated cracks in the Earth's crust rather than any local sediments. However, note the idea of deep-seated cracks may also be required to explain the migration of petroleum within the organic theory.

According to the non-organic theory, petroleum should occur universally in areas of tectonic activity. This does not appear to hold true, and this seems to be a problem for the non-organic theory.

Multilevel fields. It is observed that petroleum, in at least small quantities, is often present in horizons below many accumulations, largely independent of the composition and mode of formation of the horizon. This is known as Kudryavtsev's rule, and several examples of it have been noted¹³. The suggestion that the petroleum seeps from underneath is supported by the evidence of fractionation, although this can also be explained by migration from deep source rocks within the organic framework as well.

Methane-bearing strata in the same column show a progressive depletion in the isotope carbon-13 as one rises from lower levels to higher levels¹⁴. The organic theory holds that petroleum originating from source rocks buried several km within the earth explains these properties. The oil and gas formed would migrate upwards, thereby explaining both fractionation and Kudryavtsev's rule. However, this effect would be a natural consequence of the upward migration of primordial gases, with the heavier isotopes of carbon rising more slowly than the lighter one.

Stability with depth. It was once thought that petroleum and natural gas would not be able to survive at depths greater than a few tens of kilometres below the surface as the temperatures occurring there exceeded those

observed to destroy petroleum and natural gas in labs. Hence, it was reasoned, it was pointless to look for either the fuel or its origin in the depths of the Earth. However that picture has changed radically. Huge quantities of gas have been discovered at great depths, e.g. in the Anadarko basin in Oklahoma. Reservoirs of 'geopressed gas' have been found to underlie all major oil-bearing regions. These are sandstones and shales containing enormous amounts of gas dissolved in salt brines. Reserves of such gas are estimated at 60000 TCF (trillion cubic feet) in the US alone¹⁵, exceeding by several factors the total conventional gas reserves of the world.

In addition, vast domains of gas exist in open fractures of non-sedimentary basement rock. A deep hole currently being drilled in Germany has found these at depths of up to 4 km¹⁶. Theory had to be revised, and Chekaliuk¹⁷ showed that not only could natural gas exist at extreme depths but petroleum could, too. The earlier experiments had simply not been done at the correct pressures. In fact, the pressures encountered stabilize oil and natural gas against dissociation despite extreme temperatures, so that methane could exist up to 30 km with only 5% dissociated. Further, thermodynamic calculations show that petroleum itself is mostly stable between 30 and 300 km. Although this is heartening from the perspective of the non-organic theory, this does not necessarily go against the organic theory, as we discussed earlier.

Sugisaki and Nagamine¹⁸ have recently investigated the thermodynamic equilibrium of light hydrocarbon gases. Thermodynamic equilibrium of a gas is revealed by the concentrations of its constituents. They studied the reaction

At equilibrium the graph of $[\text{CH}_4] \times [\text{C}_3\text{H}_8]$ vs $[\text{C}_2\text{H}_6]$ is a graph of constant slope. Moreover, the temperature of equilibrium can be calculated from this graph. It was found that hydrocarbon gases released by crushing plutonic rock and natural gas from deep wells displayed these features, indicating chemical equilibrium. On the other hand, gases issuing from a peat bog, shallow gas wells, and, significantly, pyrolysis products from kerogen, coal and other organic substances did not, although the temperature was 350°C (thus exceeding the equilibrium temperature of 180°C for the plutonic gases) and the longest experimental period was 555 days. Quite naturally this is a puzzle, since if kerogen were the source of petroleum, then the hydrocarbons released through pyrolysis of kerogen should display the chemical equilibrium shown by the deep-level hydrocarbons. It should be noted that this work¹⁸ pertains to thermodynamic equilibrium of light hydrocarbon gases and not to the stability of the same.

The team explained these observations in terms of the organic theory as follows: After the decomposition of petroleum, kerogen and other heavy hydrocarbons, the gases attain chemical equilibrium at the high temperatures existing at great depths. As the gas cools, either by upward migration or by cooling of the volcanic rock (in the case of the plutons), the gas composition is frozen in once the temperature becomes so low that the gas composition effectively freezes in. To explain the negative result, i.e. the lack of equilibrium of the pyrolysis products, they are forced to make the rather unilluminating assumption that the rate of reaction was so slow that equilibrium could not be attained even after $1\frac{1}{2}$ years.

A far more natural explanation, which the authors cited above chose not to investigate, is using the non-organic theory. If it is assumed that the hydrocarbons are primordial and originate from the depths of the earth, then they would naturally display the signatures of chemical equilibrium as it would have been subject to high temperatures for a much longer time. As the hydrocarbons migrate upwards, they would, at shallow levels, be invaded by bacteria, thereby losing the signatures of equilibrium.

Critics suggest that oxidation would destroy any petroleum anyway turning the hydrocarbons into CO_2 , H_2O and coke, the constituents of volcanic gases. Since these come from deep inside the Earth, the primordial hydrocarbons, even if they existed, would have been destroyed. However that is not the full story. Substantial evidence indicates that unoxidised carbon exists at great depths. Unoxidised carbon can also exist at great depths within the organic framework, coke being produced by the decomposition of hydrocarbons.

Existence of unoxidised carbon at great depths

The following evidence suggests that large masses of unoxidised carbon exist at great depths:

Diamonds. These provide evidence of the existence of carbon at great depths in unoxidised form, i.e. other than CO_2 , since diamond is pure carbon.

The diamonds might have been associated with extremely violent explosions, since if the diamonds had risen slowly along with magma of the type spewed out by conventional volcanoes (e.g. Hawaii), they would have been transformed into graphite. As thermodynamical calculations and experience in the production of artificial diamonds show, diamonds must be cooled quickly to exist. Moreover the associated host rock contains other high pressure minerals like peridotite (believed to be one of the principal constituents of the mantle), etc. The primary deposits of diamonds are the rare kimberlite pipes, named after the now legendary South African

town of Kimberley which was once the chief source of these stones. These are deep vertical shafts, funnel-like near the surface and gradually narrowing with depth, presumably becoming a fissure extending all the way to the upper mantle where the pressure and temperature are suitable for the formation of diamonds (45 kbars and 1000°C approx.). Why are they so deep? How were they formed? Moreover, if they are volcanic in origin, as they appear to be, why is no lava associated with them? The only plausible conclusion is that the pipes were caused by extremely violent eruptions of gas that blasted a hole through 150 km of overlying dense rock. The observation, that the pore spaces of natural diamonds contain highly compressed gases including CO₂ and CH₄ (ref. 19) and the result that heavy hydrocarbons clearly distinguishable from the surrounding rocks exist in the East Siberian pipes²⁰, including the observation that bore holes into these pipes yield significant quantities of CH₄ (ref. 21) enforce the following conclusions:

- (i) Unoxidised carbon exists in the outer mantle in the form of methane and hydrocarbons, as does pure carbon.
- (ii) Volatile-rich regions exist in the inhomogeneous mantle which have been giving off hydrocarbon gases long after the formation of the earth's crust which can build up such great pressures that they simply crack through the crust in violent explosions.

Earthquakes. The eruptions of gas mentioned above, the generation of which is not disputed by the organic theory, should cause earthquakes. In fact, earthquakes have been observed to be associated with gas ejection throughout recorded history.

Greco-Roman civilization. Anaxagoras first proposed the theory that gases ('air') were the cause of earthquakes⁵ (p. 49). Seneca, Pliny, Pausanias and Aelian mention the evolution of 'wind', strange animal behaviour, great flames rising from the ground, loud roaring noises, foul smell and peculiar fog and the development of peculiar odour and muddy appearance in the water of wells and springs occurring several days or months prior to the earthquake.

Anglo-Saxon age. Newton wrote that he felt 'sulphurous fumes' were the cause of earthquakes⁵ (p. 51). Mitchell reasoned that gases caused the slow, visible oceanlike waves that roll across landscapes during major earthquakes. He also points out that the sudden deaths of large numbers of fish would be most naturally explained by the evolution of poisonous gases from vents in the ocean floor. Alexander von Humboldt summarized the then accepted theory as 'elastic fluids seeking an outlet to diffuse themselves into the atmosphere' being the cause of earthquakes. Thousands of fish, many of a nature previously unknown to local fishermen, were found floating on the water in Monterrey Bay on the day of the destructive San Francisco earthquake of 18

April 1906 (ref. 5, p. 63). Similar reports come from Japan. Hydrogen sulphide, highly toxic to fish, is a likely candidate, killing the bottom dwelling fish that are not normally caught.

Chinese civilization. More recently, at the Sungpan-Pingwu earthquake (Aug. 1976), outbursts of natural gas from rock fissures were reported. Moreover, these sometimes ignited, creating fireballs. A total of 1000 were sighted. A few hours before the earthquake, the water in local wells was observed to exhibit a violent bubbling⁵ (p. 61, 62).

These reports spanning recorded history show that methane gas is closely associated with earthquakes. In fact it is not unreasonable to suggest that earthquakes are caused by enormous build-ups of highly compressed gases containing mostly methane. This is in fact a strong support in favour of the non-organic theory, since the amounts of methane evolved are too large to have been produced by biological sources.

Mud volcanoes. These instead of ejecting lava and gas like ordinary lava volcanoes, emit mud and gas instead. The cones built up by them, consisting of solidified mud, are similar to, but smaller than, those built by the lava volcanoes. They emit mostly methane, while smaller amounts of other hydrocarbons are also present, including other inorganic gases like He, H₂, CO₂ or steam. Many mud volcanoes simply eject high pressured unconsolidated mud. In contrast, lava volcanoes emit mostly carbon dioxide and water. Mud volcanoes closely follow the underlying fault lines. This is not just commonplace, but holds for all mud volcano regions of the world. Moreover, the quantities of gas required to produce the Soviet mud volcano fields have been estimated to be several times the total gas content of the largest known gas field⁵ (p. 101). How does one explain this?

The conventional explanation in terms of the organic framework is that the gas is generated by bacterial action on the organic content of the mud. However, this has some problems:

- (i) The gas so generated would bubble up on a continuous basis, and hence extremely violent explosions of the type observed in the major mud volcano regions of the world would be extremely unlikely, as large concentrations of gas most probably not build up.
- (ii) Chemical analysis reveals that the methane also contains significant amounts of methane, propane and other hydrocarbons. Moreover, mercury, helium and other trace elements occur in the gases. The carbon isotope ratio is sometimes quite different from that expected to be obtained from a biologically derived material.

The inorganic explanation is that the gradually upward migrating gaseous hydrocarbons build up beneath impervious rocks, and then after having built up sufficient

pressure, smash through the overlying rock, creating violent explosions of the type observed. These violent displacements of gas will cause violent turbulence of the water, which would stir up the fine-grained sediment, creating the mud so characteristic of these volcanoes.

Pockmark-like craters on the ocean floor. Crater-like markings on the ocean floor have been reported from the Adriatic, the North Sea, the Gulf of Mexico, the Orinoco Delta, the South China Sea, the Baltic, the Aegean, near New Zealand, and off Nova Scotia²². Sonar experiments in the North Sea reveal shallow, circular ridges ranging from a few metres to 200 metres in diameter over an area of 20,000 square kilometres, roughly coinciding with the oil and gas producing region. It appears that individual events were responsible for creating large fields of these 'pockmarks', since one set of pockmarks occurs 10 m below an overburden of more recent sediment, while the other is visible on the surface. Hence it is estimated that while one such event occurred within the last thousand years, another occurred 10,000 years ago. Since small trickles of gas produce small steep-sided cones of mud (as in the Gulf of Mexico, where bubbles issue from the top of these miniature volcanoes), sudden releases of gas must be responsible for the craters. Primordial gas is a good candidate to explain the pockmarks.

The author also points out a remarkable coincidence between the major mud volcano regions of the world and the major oil-producing areas: (i) The Persian Gulf, (ii) the Caspian, (iii) Indonesia and (iv) Venezuela.

The South Alaskan mud volcanoes emit mostly carbon dioxide and are situated near lava volcanoes. Only three mud volcano regions are not correlated with any oil-producing regions: S. Italy, New Zealand, Black Sea. This connection arises naturally in the non-organic approach, since mud volcanoes indicate cool regions of hydrocarbon migration.

Extra-terrestrial hydrocarbons

Meteorites. If primordial hydrocarbons were incorporated in the earth during the process of formation, then one should expect to find such substances in ancient material dating from the formation of the solar system. Such material exists in the form of carbonaceous chondrites, a class of meteorites. Moreover, this type of meteorite seems to be very common. In fact, asteroids and inter-planetary material seem to be of largely carbonaceous derivation²³.

Materials previously thought to be exclusively biological in origin have now been found on meteorites. Porphyrin-type molecules are found in meteorites and are almost certainly not of a biological derivation³.

Planets. The outer planets have their atmospheres largely in the form of hydrocarbons, chiefly methane. Uranus' atmosphere may contain as much as 14% of methane gas²⁴ (p. 221). Neptune's atmosphere consists of hydrogen, helium and methane while the inner liquid shell is thought to consist of water, methane and ammonia²⁴ (p. 233).

Comets. Halley's comet (1986) was found to emit hydrocarbon gases. The core was observed to be black, presumably because of it being composed of carbonaceous material. Lang and Whitney describe the interior as blacker than coal, its blackness perhaps being due to 'an admixture of minerals, organic compounds and metals'²⁴ (p. 254).

Isotope and trace element anomalies. The following peculiarities point to an extensive upward migration of deep fluids. Moreover, mantle-derived material occurs in association with petroleum:

Helium. This is closely associated with petroliferous regions. In fact the world obtains its commercial supply of helium by separation from natural gas¹¹ (p. 69).

Argon-40. Argon and its isotope Ar-40 occur in extraordinarily high concentrations in gas fields¹¹ (p. 70). Moreover, assuming the source of the 0.1% Ar by volume in the huge Panhandle gas field to be the source rock itself implies that the source rock must have been 100% potassium to supply the required levels of Ar-40 (ref. 25). Moreover, high values of Ar-40/Ar-36 are taken as an indication of mantle-derived material²⁶ (p. 417), strikingly petroleum displays this signature.

Experimental verification

The final proof would involve an actual experimental verification of the theory. Deep wells are good tests, since organic materials cannot occur in crystalline basement rocks. Several are under way:

The Kola superdeep hole. At 12 km, this is the world's deepest well (1984). Located in the Kola peninsula, now Russia, it reached deep down into the crystalline basement. The drilling released flows of gas at all levels. The liberated gases included²⁷ helium, hydrogen, nitrogen, methane and other hydrocarbons and CO₂. This provides convincing support for the suggestion that hydrocarbon gases exist at such great depths inside the earth that they cannot be of a biological origin.

The German deep hole. This hole is located in Windischeschenbach (Oberpfalz). The depth reached during the pilot drilling programme was 4 km (1990). From 3.2 km down the drill encountered increasingly common cases of highly concentrated salt brines with gases like

methane and helium in open caves in the rock¹⁶, but no petroleum.

The Swedish hole. The discovery of an oil and/or gas field in a location ruled out by the organic theory would settle the matter once and for all. Hence, Gold⁵ (p. 172) after studying various formations across the world, concluded that the Siljan Ring, Sweden was the best candidate for the job. This is the largest impact crater in Europe. According to the non-organic theory, the impact could have led to the formation of sizeable hydrocarbon deposits since the fractures created by the impact would favour the upward migration of primordial hydrocarbons. Although the field was located primarily on the basis of seismic data, numerous oil seeps have been noted in the small sedimentary deposits of the ring-shaped depression marking the crater, carbonates characteristic of oxidised methane occur in the area and seismic observations reveal zones of porosity stacked on top of one another. Hence the primary indications were favourable.

Finally, Gold succeeded in convincing investors and a project began to prospect for petroleum in the area. This was largely supported by the state-owned Swedish electricity utility Vattenfall. Drilling began in 1986. By late 1987 a depth of 6.5 km had been attained, but no large commercial deposits had been discovered²⁸. Opponents saw in this the death knell of the non-organic theory (claiming the hydrocarbons detected were from the lubricating drilling mud injected into the ground during drilling), while Gold proclaimed a victory (claiming that significant amounts of hydrocarbons were discovered, and that large amounts lay beneath)²⁹. Due to drilling difficulties, the project stopped short of its target. It can be said that this did not rule in favour of either proposition.

However, in 1989 the Swedish drilling company Dala Djupgas Produktions recovered a small quantity of oil from 6.7 km below the Siljan Ring. Again critics dismissed the find as being recycled drilling fluid. The tables were turned yet again when the same Company discovered oil in 1991 even at the shallow depth of 2.8 km at a nearby well, the horizon of the petroleum being basement granite³⁰. Moreover the previous objection was nullified as the drilling fluid used in this case was water only. The proponents of the organic theory claimed that this oil was merely oil that had seeped into underlying fissures in the basement of rock from oil shales, since the petroleum found in the oil shales and that in the basement rock were chemically very similar. However, the non-organic theory explains this as being due to the upward migration of primordial petroleum; the two oils are similar because their common source is the same. The upward migrating hydrocarbons would have produced both the deep oil and the oil shales, the

shale providing a good trap rock that could absorb the oil on its way up. Hence, the case appears to have recently swung in favour of the non-organists.

Only drilling in the future by men of the calibre of Col. Drake (the discoverer of the world's first oil-field), Dad Joiner (the discoverer of the giant E. Texas oil-field) and P. Higgins (the discoverer of the Spindletop oil-field) can yield the answer to this intriguing question.

Conclusion

The positive and negative features of the classical organic theory have been discussed. This has been the traditionally accepted proposal, much work having been done in this field. The rival non-organic theory has so far not been accepted due to the successes of the biological theory to date in elucidating certain properties of oil-fields. However, new results from deep holes across the world are difficult to describe in terms of the biological theory. It has been shown that these new observations can be naturally explained within the non-organic framework, and that the older biological supports (mainly relating to the presence of supposedly biological material in petroleum) can also be incorporated. Hence a duplex theory combining features of both theories may be the final victor. This would perhaps involve the enrichment of existing organic hydrocarbon deposits through non-organic hydrocarbons.

The abiogenic theory derives much of its support from diverse and exotic fields such as astrophysics, cosmo-geophysics, thermodynamics, nuclear geology, etc., and considerable strides in the comprehension of these fields have led to a impressive growth of information in support of the non-organic theory.

MEETINGS/SYMPOSIA/SEMINARS

National Seminar on Bamboos and Exhibition of Bamboo Crafts

Date: 28-29 November 1996
Place: Bangalore

Seminar on status of bamboos in India and an exhibition and sale of bamboo products are arranged.

Contact: Dr H. M. Swaminath
Organizing Secretary
National Seminar on Bamboos
Vanavikas, 5th Floor,
Malleswaram,
18th Cross
Bangalore 560 003
Phone: 3311682
Fax: 080-3362935

National Symposium on Power System Instrumentation and Control

Date: 26-27 December 1996
Place: Bangalore

Topics include: Power electronics/power quality, Diagnostics and expert systems, Communications, DA/DSM, Grid operation/load despatch, Standards and standardization, Action plans, Thermal power plants, Protection, Optimization, Simulation and problem oriented papers.

Contact: Shri R. K. Hegde
Joint Director
Instrumentation Division
Central Research and Testing Laboratory
Central Power Research Institute
Post Box 9401, Sir C. V. Raman Avenue,
Bangalore 560 094
Phone: 3412915, Fax: 080-3416213

National Conference on Alternative and Renewable Energy Technologies

Date: 10-11 January 1997
Place: Hyderabad

Topics include: Solar thermal applications, Solar photovoltaic technology, Wind energy generation, Hybrid energy systems, Biomass conversion, Energy conservation and audit, energy recovery and efficient systems, Natural gas applications: fuel cell, cogeneration, combined cycle power plants, Hydrogen energy, Alternative fuels and Ocean energy technologies.

Contact: Prof. D. N. Reddy
Organizing Secretary
Department of Mechanical Engineering
College of Engineering, Osmania University
Hyderabad 500 007
Fax: 040-7017139

National Seminar on Coastal Zone Environmental Management: An Appraisal of the Contemporary Research and Development

Date: 12-14 February 1997
Place: Mangalore

Themes include: 1. Coastline and coastal zone (material and processes), 2. Remote sensing and coastal zone studies, 3. Coastal zone ecosystems, 4. Industrialization and coastal zone environment (impact of infrastructural development, waste disposal, etc.), 5. Water resources of coastal zone, 6. Coastal regulation zone (CRZ) (delimitation of CRZ, level of implementation of CRZ Act).

Fax: 0824-742367

Sálim Ali

(12 November 1896 – 20 June 1987)

Madhav Gadgil

Sálim Moizuddin Abdul Ali was unquestionably the greatest whole organism biologist of 20th Century India. His insightful observations of bird life straddled most of the century, for the earliest of these were recorded in 1907 when he was all of eleven years old. They read: 'The cock sparrow perched on the nail near the entrance to the hole while female sat inside on the eggs. I ambushed them from behind a stabled carriage and shot the male. In a very short while the female acquired another male who also sat 'on guard' on the nail outside. In next 7 days I shot 8 male sparrows from this perch. Each time the female seemed to have another male in waiting who immediately stepped into the gap of the deceased husband.'

Sálim Ali learnt about birds, not from books, nor from musty specimens in museums, but through practice; by watching them at first hand, and in days before anybody thought of conservation, by ambushing them, and shooting them for the pot. It was just such a sparrow he shot the next year, when he was twelve, that turned out to be a different species, a yellow throated sparrow (*Petronia xanthocollis*), which brought him in contact with Bombay Natural History Society, its collection of plant and animal specimens and books on natural history. From that time on he was hooked on a biological career; a career he pursued with such distinction, with little formal training. For in his first year in the college he stumbled on 'logarithms and such like

evils' and ran away to Myanmar to work with a cousin in mining wolfram. Deciding, however, that he was not cut out for business, he returned to Mumbai, read for a B A in Zoology at St. Xavier's and later spent a year of practical training in taxonomy at the Berlin University Zoological Museum. For most of his life, he held no jobs, but pursued ornithology at the Bombay Natural History Society¹.

As the philosopher Wittgenstein remarks 'practices reveal meanings'. This injunction is particularly germane for organismic biology, for the study of complex phenomena that students of this discipline confront admits of no universal generalizations. Ecology, ethology, biogeography, systematics, can therefore only advance on the basis of practical, precise knowledge about particular plants, animals, microbes or habitats². Sálim Ali spent a life time collecting such practical, precise knowledge on many aspects of Indian bird life. He unravelled the fascinating breeding system of Weaver Birds and the role of sunbirds and flowerpeckers in pollinating and dispersing seeds of mistletoes. He undertook a series of regional bird surveys of Hyderabad, Travancore-Cochin, Afghanistan, Kailas Manasarovar, Kutch, Mysore, Sikkim, Bhutan, Arunachal Pradesh. He investigated the famed Flamingo city of the Rann of Kutch, and ringed wintering water-fowl at Bharatpur to trace their migratory routes.

A. R. Rahmani

Throughout he maintained the most meticulous records and distilled his knowledge into a series of superbly written and illustrated books; beginning in 1941 with the *Book of Indian Birds*, followed by the *Birds of Kutch*, *Indian Hill Birds*, *Birds of Kerala*, *Birds of Sikkim*, and culminating in his magnum opus, the ten volume *Handbook of Birds of India and Pakistan*. His last book, the *Field Guide to the Birds of Eastern Himalayas* was published in 1977. It is these books that have been sold many times over and will undoubtedly continue to be printed and reprinted for decades to come, that have instilled a love of natural history in a section of India's educated classes, who have otherwise been singularly insensitive to the charms of tropical nature that surrounds them. For the books are not only scientifically accurate; they make for immensely pleasurable reading; Sálim Ali was not only a great naturalist, he was a man of sparkling wit and a master of the English

language as well.

Sálim Ali was a true aristocrat, a scion of the famous Badurddin Tyabji family, a personal friend of Jawaharlal Nehru and Indira Gandhi, a Padma Bhushan, a Member of Rajya Sabha, a Fellow of many scientific Academies and a winner of numerous prizes in science and conservation. But above all, he will be remembered as the man who taught Indians to appreciate, to study at first hand, to treasure, to work towards conserving the rich living heritage of the country.

Madhav Gadgil is in the Centre for Ecological Sciences, Indian Institute of Science, Bangalore 560 012, India.

Sálim Ali — A tribute*

J. C. Daniel

Way back in 1951, after a hard day of field collecting for Dr Sálim Ali's ornithological survey of the Berars, I was relaxing with him in the forest rest house at Chikalda, now part of the Tiger Project Sanctuary of Melghat in Maharashtra. I had joined the Bombay Natural History Society the previous October, and I had been brought out on a bird survey and was very much on trial. Apparently I had not been found wanting. The 'old man', a term which was used with the greatest respect by the staff of the Society who were very fond of him but who found his unbending principles rather trying occasionally, had decided to unbend a little and we were discussing my background.

When he realized that I had been brought up in Kerala, he talked about the bird survey he had conducted in Kerala, then the States of Travancore and Cochin, in the 1930s and the people he had met. One among them was a Dr Jivanayakam who had been secretary of a fact finding committee, which was investigating the practices, both good and bad, of aided educational institutions. The Committee and Sálim Ali's survey party often shared the same dak bungalow and they had become friends particularly when the old man found that the other had more than a casual interest in the study of birds, though his specialization was in education.

As we talked about this person he asked me whether I knew or had heard about him. When I told him that Dr Jivanayakam was my father he was struck dumb with amazement. As he described this incident in his autobiography, *The Fall of a Sparrow*, it was one in a million chance that he should have been working with the son of a man he had known decades earlier. I think neither my father nor I had tried to contact him or speak of this acquaintance when I was trying for the job of research assistant at the Society. The rapport that we then struck stayed with us for the next 36 years of our association. To me, as to the many scientists who joined the Society during this period of our association, he was a father figure to be emulated, for there was little that was not good in him. His attitude towards work, for instance. He was a person who believed in striving hard when opportunities offered the chance.

In the field we had no work hours but neither had he. If we worked 14 hours it was with the knowledge that he would certainly put in 18 hours and would not be paid a penny in the bargain. He believed, as Gandhiji did, in the dignity of labour and nothing was below his dignity to handle. He agreed with Gandhiji that it is not the type of labour that gives you status and dignity but that dignity rests on your own self-assessment and self-confidence.

A great and admirable lesson that one learned working with Sálim Ali is the gravity and care necessary in the handling of money, especially public funds. The accountability not only to the donor but also to oneself,

J. C. Daniel, former Director, BNHS is currently a member of the Executive Committee, BNHS and chairman of the Salim Ali Wild Wings Trust.

that it must be frugally spent and made to give the maximum benefit, was imprinted firmly in the minds of all his scientists and students. Nothing was said but the example was set. He had worked on shoe-string budgets throughout the major portion of his bird survey collection career, depending largely on the munificence of the now vanished species, the maharajas and princes of India. It was in their States that he did his major bird study surveys. The only assistance he had was from the BNHS which gave him the services of a Skinner for the bird collection that he gave them. I do not think that except for the time he was the nature education organizer in 1927, he ever drew a salary in his life till he became a National Professor of Ornithology in the 1980s. From the grants he received from the maharajas he drew nothing but his living expenses, all the rest was ploughed back into collection and study of his first love – the birds of the Indian subcontinent.

All the bird surveys had a target. In our Berar survey, we were specially looking for the white-fronted tree pie, a species which is now restricted to the rainforests of Kerala, but had once been recorded by a reliable ornithologist from Berar. The surveys along the Western Ghats, hills of central India, Bastar and Orissa looked at the discontinuous distribution of rainforest birds now restricted to the Western Ghats of the south and the forests of eastern India. He was collecting evidence for a hypothesis known as the Satpura hypothesis propounded by Dr Hora, the then director of the Zoological Survey of India, on the route of movement of these species now existing at two corners of an India, divided by over 2000 km of unsuitable country in between. The Hyderabad survey looked for the Jerdon's courser, a bird that was subsequently to be rediscovered in Cuddapah district by one of Sálím Ali's young field biologists. Another notable rediscovery was of Finn's baya after a period of over 50 years in the Kumaon Terai.

Sálím Ali was as active in the field of conservation as he was in ornithology. He was probably the person who had travelled to all the obscure regions of the Indian subcontinent at one time or other of his life and knew the country and its forest intimately. His knowledge and experience were respected, and his timely intervention saved, for instance, the Bharatpur Bird Sanctuary, now the Keoladeo National Park, and the Silent Valley National Park.

As a prelude to the magnificent ten volumes on Indian birds which he completed by 1974, almost all the surveys gave rise to a book, *The Birds of Kutch, The Birds of Travancore and Cochin*, later published as *The Birds of Kerala, The Birds of Sikkim and The Birds of the Eastern Himalayas*, each a popular version of the data collected by the surveys of the area. These and the

ever popular *Book of Indian Birds* were to familiarize bird watching and bird study as excellent forms of relaxation in a stress-filled world.

His surveys and individual bird studies were examples of how much information can be obtained with a minimum of equipment, a notebook and pencil, a pair of binoculars and an alert, analytical mind. The precise notes he made during his bird surveys remain some of the best examples of data collecting.

It was a teacher that Sálím Ali really excelled. The Bombay University had recognized the Society as a Research Institute in Ornithology with Dr Sálím Ali as the research guide. His methods were innovative and the student was left to develop his own ability and initiative, with guidance subtly rendered through discussions. The bond that was so established, was in the best traditions of the Indian *guru* and *shishya* relationship. He was thus able to expand the research capabilities of the Bombay Natural History Society when the opportunity offered.

Recognition came late to Sálím Ali but came abundantly. The Asiatic Society's gold medal for researchers in Asiatic Zoology, Padma Bhushan and late the Padma Vibhushan for continued distinction in zoology from the Government of India, the Sunderlal Hora Memorial award of the Indian National Academy of Sciences for 'outstanding contributions to Indian ornithology'; The degree of D Sc from the Universities of Aligarh, Delhi and Andhra. The Union Gold Medal of the British Ornithologists Union and several other international awards of recognition including the Paul Getty International Prize for Wildlife Conservation.

The BNHS was very much a part of Sálím Ali's life from the time he timidly entered its portals as a small boy with a yellow throated sparrow in his hand. He was a member of the Society for over 69 years and the organization gradually became synonymous with him. It was his family and all that he cared for. To the Society he left whatever he thought was valuable in his possession.

A man with a fine natural modesty, he was humane, selfless, sensible, and with a lively sense of humour. Above all, he had what Gandhiji also had and which the Arabs call 'Baraka', the quality of being able to bestow blessing or benediction.

Sálím Ali was a non-conformist, a man who for many years walked a lonely path divergent from the main stream of science in India. It is a tribute to his determination and genius that at the end of his life he had a sizeable population of the conformist main stream following him, or at least appreciating and commending his more or less single-handed efforts to present the study of the birds of his land, the ethereal spirits of the air, to his countrymen and to the world.

Deploying student power to monitor India's lifescape

Madhav Gadgil

Along with his many scientific contributions, Sálim Ali will be remembered for a whole series of superbly written and illustrated books on Indian birds, books that played a key role in stimulating popular interest in India's rich living heritage. In honour of this great naturalist the Indian Academy of Sciences will launch on the occasion of his birth centenary a project called 'Lifescape' as a part of its initiative to enhance the quality of science education. This project aims to publish illustrated accounts of 2500 to 5000 Indian species of microorganisms, plants and animals. These accounts would help high school, college and postgraduate students and teachers of biology to reliably identify these species, and thereby constitute a basis for field exercises and projects focusing on first hand observations of living organisms. The information thus generated could feed into a countrywide system of monitoring ongoing changes in India's lifescape to support efforts at conservation of biological diversity, as well as control of weeds, pests, vectors and diseases. These accounts would also help create popular interest in the broader spectrum of India's biological wealth, much as Sálim Ali's books have done for birdlife over the last fifty years.

INDIA is a land of great natural diversity, diversity that embraces mangrove swamps of Sunderbans and rain forests of Western Ghats, coral reefs of Lakshadweep and wetlands of Bharatpur, hot deserts of Rajasthan and cold ones of Ladakh. Thanks to this diversity of environmental regimes and its position at the trijunction of African, Eurasian and Oriental biotas, India is one of the world's 12 megadiversity countries. Over 125,000 species of living organisms have been described from our subcontinent; it probably harbours another 400,000 awaiting to be described. India is also one of the global centres of diversity of crops and livestock¹⁻⁵.

This biodiversity and its knowledge is now assuming great significance, for the second half of twentieth century belongs to sciences and technologies of life. Beginning with the elucidation of the chemical nature of heredity, life sciences have made rapid strides in understanding of the working of the machinery of life. Knowledge is power; and this understanding has been translated into an ever growing sophistication in manipulating living organisms. This has opened up many novel possibilities of application, and it is expected that the resulting biotechnologies may account for as much as 40% of the world economy in the coming decades. The stupendous diversity of life is the raw material for these applications and an understanding of this diversity must go hand in hand with a deepening understanding of the working of life to reap fully the fruits of modern advances in biological sciences^{6,7}.

Our weaknesses

Unfortunately, India's scientific base of knowledge of this diversity of life and ways of adding value to it is very weak. Only some 20% of the species we harbour are likely to have been scientifically described; but even of these a large proportion has been described by British and other Western scientists⁸. Their specimens are located in the Museum of Natural History or Kew Herbarium in London; but are often absent from Indian collections. Thus A. K. Ghosh (pers. comm.), formerly Director of Zoological Survey of India reports that of 82,000 described species of animals, specimens of only 51,000 species are located in the Indian Museum in Calcutta. Specimens of an additional 1000 animal species may be available with Universities or institutions like the Bombay Natural History Society; that still leaves 30,000 species for which the specimens are available only abroad. For some groups like birds we have in India specimens of all the species; but, even in this case there are likely to be 10 times as many specimens abroad as in India (J. C. Daniel, pers. comm.). On the other hand, with animal groups like aphids, India holds specimens of only about 10% of the described species (A. K. Ghosh, pers. comm.). Aphids are important crop pests and now foreign agencies holding Indian material are charging thousands of rupees for help in identifying a single specimen. We are also very unfavourably placed with respect to crop genetic resources the rice germplasm collection of the International Rice Research Institute is, for instance, richer, even in terms of Indian material, than any of our own collections. We do not have a single properly organized and internationally

Madhav Gadgil is at the Centre for Ecological Sciences, Indian Institute of Science, Bangalore 560 012, India and Biodiversity Unit, Jawaharlal Nehru Centre for Advanced Scientific Research, Jakkur P.O., Bangalore 560 064, India.

recognized repository of microbial cultures either.

We are equally unfavourably placed in terms of scientific capabilities of identifying, working with, adding value to biodiversity resources. India boasts of the third largest scientific manpower in the world. Our Botanical and Zoological Surveys have very long history, and together employ over 1000 trained biologists. Our more than 6000 colleges and University departments employ another 20,000 or so. Every year more than 100,000 students get a bachelor's degree in one of the branches of Life Sciences. But only a very small fraction of these get an exposure to India's living wealth. Practically none of our master's degree holders in zoology is able to name more than 5 to 10 species of birds, lizards, fish or butterflies put together. This is because they are never encouraged to look at living creatures abounding around them, their training being confined to identifying a few dead specimens, or dissecting a still living cockroach or a dead pigeon. Given such a training programme few teachers of biology know much of the living wealth of India either.

Monitoring biological populations

Identification of the great diversity of living organisms around us, a majority of whom, especially smaller animals like mites and marine animals like bottom dwelling worms are yet to be described is a challenging task. This would call for a high level of professional training and infrastructure. But equally significant is a task which can be undertaken without sophisticated technical inputs – this is the task of monitoring the ongoing changes in the populations of living organisms through the length and breadth of the country, a task we are committed to undertake as a party to the Convention on Biological Diversity^{8,9}. It is very much in our interest to do so for a variety of reasons – to appreciate if populations of medicinal herbs are on decline through overharvests, or if wild relatives of cultivated plants are being eroded through habitat transformations; to appreciate if populations of weedy species such as water hyacinth are exploding and choking our wetlands, or whether new species of insects are assuming pest status for our crops; and to keep track of populations of vectors of human diseases such as mosquitoes. This is a task which does not call for a capability to identify all of our known 125,000 species – or unknown 400,000; but a task which can be effectively discharged by developing the capability to reliably identify a few hundreds, or a few thousands of species. The Foundation for Revitalization of Local Health Traditions has identified a set of 300 species of medicinal plants of particular significance from Karnataka, Tamil Nadu and Kerala. To this we may add a couple of hundred species of edible fishes, a

few hundred species of butterflies, frogs, turtles, birds, mammals of conservation significance, a few hundred species of insect pests of crops, a few hundred species of bacteria, fungi, intestinal worms and other human and livestock parasites and their vectors and so on. The list may come to a few thousand species of considerable significance that ought to be monitored throughout the entire stretch of our country's landscape, waterscape and seascape. Only a few hundred out of this set of a few thousand may be present in any given locality. To develop the capability of reliably identifying such a subset is not a difficult task at all; it is a task that could be mastered by any interested lay person. After all many enthusiastic bird watchers can readily identify two hundred to three hundred species of birds; and every practising fisherman and woman easily identifies a few hundred species of fish and other marine animals. It is therefore quite possible for students and teachers of biology to acquire such a capability, each for their own locality, given adequate support in terms of literature, and given that there is adequate motivation to acquire this knowledge.

Two facets of biology

To assess this proposition, we must take a second look at the teaching of biology. Teaching and research in biology are addressed to two facets of life:

- (a) Functioning of life based on a machinery largely held in common by organisms as different as bacilli, moulds, trees and birds,
- (b) The resulting diversity of living organisms and their associations.

The functioning of life is the subject matter of the disciplines of biochemistry and molecular biology, physiology, developmental biology and genetics. The diversity of life is the subject matter of disciplines of morphology, taxonomy, evolution, ecology, ethology and biogeography. The former set of disciplines may be termed functional biology, the latter organismic biology. The teaching of these two branches, functional biology and organismic biology poses different challenges. In teaching functional biology the emphasis has to be on the underlying commonalties; genetic code is genetic code, and Krebs's cycle or transmission of nervous impulses across synapses are the same whether taught in Madurai or Madrid, Malawi or Massachusetts. In teaching of organismic biology, however, the focus can, with profit, be very different. The variety of birds or butterflies is very different and much greater in Madurai than in Madrid, in Malawi than in Massachusetts. To teach functional biology in Madurai on the basis of textbooks and laboratory experiments designed in

Massachusetts can be very sensible, to teach organismic biology in a similar fashion does little justice to the wealth of life in and around Madurai.

There is yet another significant difference. Our understanding of functional biology is rapidly advancing. But this calls for probing into the machinery of life with sophisticated instruments, with expensive chemicals. Given our limited financial resources, Indian universities and colleges are at a disadvantage in arranging laboratory exercises for teaching many aspects of functional biology. Our understanding of organismic biology is also advancing, though not at the same rate as our understanding of functional biology. Twentyfive years ago, it was estimated that there were around 3 million different species of living organisms, of which some 1.6 million had been described. Subsequent studies have led to an upward revision of this estimate to somewhere between ten and thirty million. This implies that most of the diversity of life has not even been documented in terms of a simple description and naming of species, let alone taken further in understanding of the ecological role, geographic distribution, evolutionary relationships of that species. Most of these unknown species are believed to occur in tropical forest and coastal habitats. They must be identified, their distribution, their ecological role investigated where they occur in their natural setting; that means a tremendous opportunity for us in India in adding to the store of biological knowledge.

Untapped opportunities

Of course, some of these investigations require considerable support in terms of literature and museum or herbarium specimens^{8,10}. Tragically little of such support is available within our country. But description of new taxa is only one part of research in organismic biology; information on the distribution and abundance of many species of known significance is also of considerable relevance. As stressed above, much of this is of applied value – we need to know whether populations of medicinal plants like sarpagandhi, *Rauwolfia serpentina* or wild relatives of cultivated plants like wild rice, *Oryza nivara*, are threatened with extinction, where and when populations of crop pests like brown leaf hopper or vectors like anopheline mosquitoes are undergoing rapid increase. Such information is vital to efforts at conservation of our rich biodiversity resources, and attempts at control of pests, diseases, vectors.

This kind of information, information for monitoring populations of thousands of species of human significance needs to be continually collected from all over the country. There are of course centralized agencies entrusted with the task of doing so, but they are unable to do full justice to this responsibility. Thus we do have a

Botanical Survey, a Forest Survey, a Central Institute of Medicinal and Aromatic Plants; yet we have essentially zero information on the status of hundreds of species of medicinal plants of the country. We do have a Central Institute of Communicable Diseases, but its machinery could not monitor the outbreak of rat and flea populations preceding the plague outbreak of 1994.

Obviously these centralized organizations must be supported by a much more widespread network of centers for monitoring the populations of a number of species of living organisms across the country. Undergraduate science colleges along with high schools and centres of post-graduate studies are clearly the answer. These span every one of country's 500 districts, a vast source of scientific competence that has been made little use of. The botany, zoology, microbiology teachers and students of these colleges could easily study and document the distribution, abundance and seasonal and annual changes in populations of a few hundred species of organisms in their own localities. Indeed, there have already been several interesting experiments along these lines. Around the Palamau Tiger Reserve in Bihar, biology teachers from some undergraduate colleges have formed a network for monitoring the Tiger Reserve ecosystem working in collaboration with the Wildlife Wing of the State Forest Department (D. S. Srivastava, pers. comm.). The Ahmedabad based Center for Environmental Education has extensive programmes of involving high school and college teachers in monitoring a variety of environmental parameters¹¹. The Western Ghats Biodiversity Network coordinated through the Centre for Ecological Sciences at the Indian Institute of Science involves botany and zoology teachers from about 15 colleges working with teams of 5–15 students to map local landscapes and investigate the occurrence of species of a number of groups of plants and animals including mosses, flowering plants, aquatic insects, fishes and birds¹². Such studies not only would constitute a valuable learning experience, they would also generate considerable information of potentially applied value which could feed into a properly organized bioresource monitoring system of the country.

Fresh approach

It is thus entirely possible to take up this challenge. But to do so successfully calls for a fresh and different approach to the teaching of organismic, in contrast to functional biology. Functional biology has to be taught on the basis of a largely uniform curriculum, and a curriculum focused on laboratory experiments. Organismic biology could be taught much more meaningfully on the basis of a flexible curriculum focusing on locally occurring plants, animals and microbes, and should supplement laboratory exercises by extensive field observations. These requirements of flexibility, of scheduling

field observations, and of assessing field based studies do pose difficulties, but these are challenges that can surely be surmounted with some effort.

Such an approach need not however involve additional burden of course work for students and teachers. Our high school curricula already include environmental studies. Our B Sc and M Sc biology courses provide for teaching of morphology, classification, evolution, ecology, biogeography. What needs to be done is that part of this material be substituted by other material – more flexible, and emphasizing first hand observations. Thus in zoology courses we have a paper on chordates. As a part of this paper students learn of platyrrhines, the primitive monkeys found in South America, but they do not learn that Jodhpur has troops of hanuman langur, *Presbytis entellus* which has been the subject of fascinating ecological and behavioural studies in Rajasthan, Gujarat, Uttar Pradesh and Himachal Pradesh. They are not encouraged to estimate these monkey populations or observe their social behaviour. At the same time, the Government of India has spent huge sums of money to sponsor through Zoological Survey of India a survey of primate populations of India, a project that was abandoned half way through, a project whose results have never been published. If all zoology students in India had been taught of the identity of the macaques, langurs, gibbons in their respective localities and encouraged to yearly maintain records of the monkey troops in their own area, we could have accomplished not only a one time primate survey, but an ongoing monitoring of primate populations in a most cost effective fashion. It would be no serious loss if in the process, we teach the zoology students a little less of squirrel monkeys in South America.

Such broadbased programmes of monitoring populations of some selected set of species have been successfully conducted in many parts of the world, primarily drawing on the resources of amateur bird watchers. The best known of these is the Christmas bird count of the National Audubon Society in the United States of America. Started in 1900, the programme now involves over 45,000 volunteers. The counts are conducted in over 1500 designated areas, each 12 km in radius. Within a week or two of Christmas, each designated count area is censused for one day, with participants seeking out and counting all birds in the area¹³. Parallel exercises have been conducted in India, such as the wintering waterfowl count sponsored by the Asian Wetland Bureau. Project Lifescape visualizes similar countrywide monitoring, drawing on biology teachers and students and covering the entire spectrum of living diversity.

Lifescape of India

An interesting approach to teaching organismic biology

in this way would be to do what was proposed above, i.e. to come up with an overall list of plant, animal, microbial species of India whose first hand observations might form an important component of teaching of environmental sciences or biology – not all species everywhere, but in some part of India or other. For instance, this list may include a few of primate species – (1) bonnet macaque, (2) rhesus macaque, (3) Assamese macaque, (4) hanuman langur, (5) Nilgiri langur, (6) hoolock gibbon. Only one of these species may be selected for study in any given locality – for instance, bonnet macaque in Madurai, hanuman langur in Jodhpur, hoolock gibbon in Shillong and so on. This is not to suggest that students should close their eyes to species outside this list; the listed focal species should instead serve to build a foundation for getting students involved in observing other living organisms as well. Employing the study species as an example, the students would then observe its members under natural conditions and in the process become familiar with the morphological characteristics of primates, the place in classificatory scheme and evolutionary relationships of macaques as a part of the Chordate paper. They could observe their habitat use, food preferences and estimate their numbers as a part of the ecology or environmental biology paper, observe their social behaviour as a part of the behaviour paper, look at their geographical distribution as a part of the biogeography paper, and so on. Some of their observations could also feed into a country-wide project of monitoring primate populations.

The six primate species noted above would be part of an overall national list of microorganisms, plants and animals. This list has to be a subset of the estimated 500,000 and the described 125,000 or so species of India. We therefore need some criteria for inclusion in the total list. Possible candidates for such criteria include:

- Economic significance, for instance, medicinal plants, wild food plants, plants producing minor forest products such as tendu leaves, genetic resources such as wild relatives of cultivated plants or domesticated animals, animals which may be bred under domestication with profit, such as in butterfly farming, crop pests, weeds, crop pollinators, vectors of human diseases, fresh water fishes.
- Striking appearance and therefore ease of and attraction to observation: larger mammals, commoner species of birds, crocodiles, fireflies, dragonflies, plants with attractive flowers, large trees.
- Cultural significance: Monkeys, peafowl, *Ficus* species such as peepal.
- Conservation significance, for instance, endemic or threatened species.
- Desirability of having representatives available in all parts of the country, from Port Blair in Andamans to

SPECIAL SECTION

Leh in Ladakh, and from rainforests of Mizoram to concrete jungles of Mumbai.

- Desirability of having representation of all groups of living organisms. Thus we should include seaweeds, lichens, mushrooms, ferns along with higher plants amongst wild food plants.

How big should such a national list be? It has to be a subset of the 125,000 described species of living organisms. Any given educational institutions could readily include an area within a radius of 3 km; say a total area of 32 km² for the field studies. The total area of our country is 32 lakh km², larger by a factor of 10 to the power of 5. Ecological theory tells us that depending on the group of organisms concerned the total number of species encountered increases at a power of 0.2 to 0.4 with the area. This implies that a study area of 32 km² may harbour between 1% and 10% of the total; i.e. between 1250 and 12,500 species of microbes, plants and animals, all put together. These are likely to be overestimates, for the habitats readily accessible to educational institutions would surely be poorer in living diversity than the more natural habitats for which these estimates should hold. But even then students at any educational institution should easily have access to several hundred species of living organisms in their close vicinity. Anthropological studies in Amazonian forest have shown that indigeneous people have distinct names for as many as 1500 species of local plants and animals. Trained biology students could then also learn to know several hundreds, say 250 to 500 species without much difficulty. Following the rule of thumb of 1% to 10% of total set being present in the vicinity of any given school or college in the country, the national list has to lie in the range of 2,500 to 50,000. For reasons of practicality it is best to aim the lower part of this range; so we may aim for a national list of 2500 to 5000 species. Such a national list may be viewed as the list of indicator species for assessment of the status of biodiversity in the country for the purpose of Indian national reporting to the Convention of Biological Diversity^{9,14}.

It is our proposal then that the locally available subset of a few hundred out of this national list of 2500 to 5000 species be employed as subjects for first hand observation as a part of teaching of environmental science, or of branches of biology such as morphology, classification, evolution, ecology, biogeography, behaviour over the three years of high school, 2 years of junior college, 3 years of undergraduate and 2 years of M Sc curriculum. Again not every student may end up observing all the locally available species, many may be subject to special observation as an individual or group project by one or few of the more interested students. Table 1 suggests a possible taxonomic breakup of a set of 2500 species and Box 1 a possible way of apportioning these species at different stages of high school and

Table 1. Possible taxonomic break up of a set of 2500 species

college education. The Appendix provides a possible model account of one of these species including a set of possible student projects.

Environmental setting

This subset of focal species of any particular locality would occur in a specific environmental setting. It would be desirable that the curriculum include a first hand study of this setting which could become a part of the environmental sciences, biology, geography or geology paper. Indeed study of this setting is the subject of a newly emerging discipline known as landscape ecology. Landscape ecology views any region as a mosaic of repeated occurrences of a set of landscape element types which may occur as patches, for example, paddy field, grassland, pond, evergreen forest, scrub savanna, human habitation or as linear or branching elements such as watercourses, roads, electric lines. It would be desirable to select one particular area, say of ten to thirty square kilometers near the high school, college or University and to prepare a good map of the area in terms of occurrence of different types of landscape elements. Satellite imagery could be a very useful aid in the preparation of this map, and such a study programme could be linked to a programme of remote sensing literacy. This landscape map could then be the basis for organizing the

Box 1

The students of environmental science and of biology in any given locality may become acquainted with the subset of the total 2500 species present in their locality in a graded fashion beginning with the commonest, most striking, easily identifiable, most significant species and adding on the less common, less significant, more difficult species at higher standards. Consider as an example, 95 species of birds (out of a total country wide set of 200 species) present in any given locality. In the 8th standard the students may begin with Jungle Crow, Indian Myna, House Sparrow, Roseringed Parakeet and Pariah Kite, adding species like the Ashy Wren-Warbler, Blyth's Reed Warbler, or Sparrow Hawk at the 2nd or 3rd year B Sc level. The 95 species may be covered in the following sequence. VIII (5), IX (5), X (5), XI (10), XII (10), I BSc (20), II B Sc (20), III B Sc (20). There would of course be no expectation that the students would not explore and get to know bird species outside this list. In fact, the account for the Indian Myna would mention how to discriminate it from very similar bird species such as Jungle Myna drawing attention to this additional species. In a locality where Hill Mynas are present, the students would naturally notice them as well, once they begin observing Mynas even if the Hill Myna may not figure amongst the list of 200 species of India selected for the purpose of this programme.

study of distribution, abundance, behaviour of the focal subset of species. It could, for instance, be used to organize information on distribution of habitats where mynas or mosquitoes breed, or a certain species of medicinal plant occurs. Ancillary information, such as older satellite imagery, official documents or oral accounts by local people could be used to reconstruct the dynamics of change in the study locality and to use it to infer changes in availability of habitats preferred by species under investigation.

Economic significance

A study of the economic significance as well as the folk knowledge and usage of the focal subset of species could form a part of a paper such as environmental science/economic botany/economic zoology/applied biology/sociology/economics. The economic significance may range from a variety of services such as food or medicine or disservices such as crop pests or vectors of human diseases. Such studies could be linked to other parts of the curriculum as well. For instance, a local medicinal plant may be the source of a specific alkaloid which could be studied as a part of the biochemistry

course. The local uses of the medicinal plant could be studied as a part of the social studies, sociology or economics courses. In any event, linking the study of biology to species with specific known significance would greatly enhance the understanding of the subject by students, as well as motivate them to contribute to programmes of management of the species, whether of conservation or control.

Management regimes

A first hand study of ongoing attempts either at conservation or control of the focal subset of species, as well as of the land-use management of the entire study area at the landscape level could also be usefully incorporated in environmental science/biology curricula. Focusing on species level, there may be relevant local traditions such as protection to peafowl or peepal trees, or official measures such as a ban on hunting of all birds, or of cutting of any tree from a reserved forest. There may be programmes of propagation of medicinal plants, or control of rat or mosquito populations. It would be worthwhile studying the intentions behind such measures, as well as the efficacy of their actual operation in the field. It would also be worthwhile undertaking field studies and documentation of phenomena such as harvest, trade, marketing of medicinal plants or poaching of quails and partridges.

At the landscape level there would be a variety of regulatory measures, as well as developmental activities, both of which should be investigated and documented. These may include prohibition of encroachment on reserve forest land, or in the city prescription of the ratio of open to built up land. It would be worthwhile to monitor the efficacy of the regulatory measures, the ongoing changes and their impact on populations of the focal subset of species under study. Such investigations would not only be a useful device of teaching environmental science/biology but of generating an environmentally literate citizenry.

Organizing information

The exercises proposed above would be valuable to teaching of all aspects of environmental science/organismic biology. Additionally they could generate information of applied value in at least four different contexts.

(1) Conservation of valued species, such as wild relatives of cultivated plants, crop pollinators or threatened species of wildlife. Currently State Forest Departments, Forest Survey of India, Wildlife Institute of India, Botanical and Zoological Surveys of India are engaged in

some monitoring with this end in view.

(2) Utilization of economically valued species such as medicinal plants. Currently some drug companies have limited monitoring of their resource species.

(3) Surveillance of crop pests or livestock diseases. Currently state departments of Agriculture, Horticulture, Animal Husbandry and Veterinary Services have monitoring programmes of this nature.

(4) Surveillance of vectors of human diseases. Currently the National Institute of Communicable Diseases has limited programmes of such monitoring.

Potentially the teaching programme sketched above could generate much information of value in all these contexts. While all environmental science/biology students from 8th standard onward may be involved in the broader programme, a limited set of motivated students may participate in generating more reliable data to feed into an information system for applied purposes of conservation, economic utilization or control. Such students may be those who opt to undertake special projects as an optional part of the regular curriculum, or those who participate in some special activity such as a National Earthwatch Corps on the model of the National Cadet Corps or National Service Scheme.

This information should feed into new well-designed, vigorous programmes of monitoring all aspects of country's environment, including of course the landscape. Such a system should take full advantage of the modern informatics technologies and be organized as an interlinked network of computerized data bases^{1,7,15}. Educational institutions should be part of such a network involving a number of other agencies such as Forest, Botanical and Zoological Surveys, National Remote Sensing Agency, National Centre for Communicable Diseases, Forest, Agriculture, Animal Husbandry and Health Departments of State Governments, etc. The overall effort may be co-ordinated by a programme such as the Natural Resources Data Management System of the Department of Science and Technology¹⁶. Educational institutions should not only feed information into such a network, but should have access to information supplied by other agencies to facilitate students in taking projects using more synoptic information such as studies on geographical distribution patterns of their focal species.

Public awareness

Apart from becoming an integral part of the educational system, such an effort, based on the availability of good illustrated accounts of some 2500–5000 significant species of living organisms of the country could trigger off popular interest in the broader spectrum of the country's living diversity. At the time of independence there were

hardly any amateur bird watchers of Indian origin in our country; today there are hundreds of bird watchers' clubs scattered throughout the country. An important cause behind this transformation is the availability of good pictorial guides beginning with Sálím Ali's Book of Indian Birds first published in 1941. This has been followed by a series of other field guides often of excellent quality. To cite a few examples, these include Pascal and Ramesh¹⁷ on trees and lianas of Western Ghats, Tadulingam¹⁸ on Indian weeds, Mathur¹⁹ on coelomycetes, Daniel²⁰ on amphibians and reptiles, Whittaker²¹ on snakes, Gay, Kihimkar and Punetha²² on butterflies, Vijayalakshmi and Ahimaz²³ on spiders and Chhappargar²⁴ on seashore animals. In addition, there are the volumes of fauna of India and a number of excellent floras. But much of this latter material is too technical and of little practical use to non-specialists, even to Biology M Sc's. For instance, there is no ready aid for us to identify such striking groups of plants as lichens or of animals as dragonflies. None of this material also tells us how to go about assessing the populations of the species, or the many interesting questions that may be posed about their ecology, behaviour, distribution. The proposed material on the 2500–5000 species should fill these manifold gaps and make it possible for the citizens of India not only to become familiar with but ask intelligent questions about our living companions – not just birds, but butterflies and wasps, earthworms and orchids, starfishes and toads, lichens and lizards. If many of us can easily get to know them, their fate would become much more meaningful to us, contributing to a broader public concern for the health of India's environment. To serve this purpose, we must of course keep in mind what Sálím Ali was so notable for, namely, that 'besides providing factual scientific information to the reader it is just as important to make the account a pleasurable reading'²⁵.

Laying the foundation

Such an effort percolating the educational programmes at high school, college and university level, as well as promoting public awareness cannot of course substitute for the need to develop higher level skills and facilities to investigate the total range of country's biodiversity, at least two orders of magnitude higher than the proposed set of 2500–5000 species^{4,10,26,27}. But this effort would surely help attract more talented scholars and generate further public support for that effort. It would thus be an important foundation for this more advanced effort. At the same time it could in itself help create a very efficient system of monitoring the status of country's biodiversity, as well as programmes to control pests and vectors.

Organizing the effort

The Indian Academy of Sciences proposes to co-ordinate such a countrywide effort as a part of its initiatives to enhance the quality of science education, as well as publish scientific literature. It would work with a range of actors in this effort. These would include:

a) Systematic biologists with Botanical and Zoological Surveys of India, research institutions such as National Institute of Oceanography and with the Universities and Colleges.

b) Interested teachers at the High School, College and Post-graduate levels.

c) Institutions active in conservation and nature education such as Bombay Natural History Society, World Wide Fund for Nature – India, Centre for Environmental Education and C.P. Ramaswamy Foundation.

d) People's Science Movement groups such as Kerala Sastra Sahitya Parishat.

e) Knowledgeable practical ecologists, such as the tribal field guide Natarajan of the Annamalai Wildlife Sanctuary who brought the presence of Peninsular Bay Owl to the notice of scientists.

Interested people drawn from such groups should then be organized to decide upon and work towards the following objectives:

a) Deciding on the criteria to select the set of 2500–5000 species – or any other number agreed upon. These criteria should reflect adequate coverage in terms of: (i) taxonomic groups, (ii) geographical distribution, (iii) habitat preference, (iv) human significance in relation to economic, aesthetic, conservation or other considerations.

(b) Arriving at the actual list of species by applying these criteria.

(c) Deciding on what sort of descriptive/illustrative material should go into the account of each species. This could relate to morphology, habitat preference, seasonal changes, notable behaviour patterns, geographical distribution, relationship to humans, ways of discriminating from other related species, names in Indian languages, techniques for assessing population status, suggestions for student projects (see Appendix for a possible example).

(d) Commissioning the actual writing up of the accounts with the help of a panel of experts, which may include practical ecologists like Natarajan mentioned above.

(e) Peer review, revisions and editing of the prepared accounts.

(f) Translation of the accounts in Indian languages.

(g) Deciding on the form/s in which the material should be published and distributed. For instance, the material could be in several volumes on the model of

Ali and Ripley's *Handbook of Birds of India and Pakistan*. It could be supplied as loose-leaf material in ring files so that a high school, for instance in Shillong may only order the accounts of species present in Meghalaya prescribed for study by the State Department of Education. It could also be published electronically, as CD ROMS or on the internet.

(h) Actual production and distribution, hopefully so that at least some of the species accounts reach every high school, college or university, as well as homes of interested citizens throughout the country.

(i) Raising the funds for such a programme. This would especially involve honorarium for writing the accounts, preparation of illustrations and finally publication. At Rs 200 per species the writing and illustration would come to Rs 5 to 10 lakhs. If each account averages 3 pages, this would entail publishing 7500 to 15,000 pages. At Rs 300 per page this amounts to Rs 22.5 to 45 lakh. Another Rs 5 lakh may be required for co-ordination of the whole project, resulting in a budget of Rs 32.5 to 57.5 lakhs. Translation and publication in Indian languages would entail further expenses. It may be noted that these estimates are a small fraction of the three billion dollar budget projected for the grandiose systematics 2000 project, currently proposed as the basis of the effort at taxonomic capacity building for worldwide implementation of the Convention on Biological Diversity²⁸.

The Indian Academy of Sciences will be launching this programme in November 1996 to commemorate the birth centenary of Sâlim Ali, one of the Academy's most distinguished fellows. With this objective, the Academy is joining hands with the Indian Institute of Science and the Jawaharlal Nehru Center for Advanced Scientific Research to organize a discussion meeting that would bring together a group of over 100 people representing the many different sets of actors mentioned above. This meeting would debate on the specific content and time schedule for the project. But apart from this meeting suggestions, including offers of help and participation from all interested citizens of India; biologists, educationists, nature lovers would be most welcome. These should be addressed to the convener of the project, Madhav Gadgil at the Centre for Ecological Sciences, Indian Institute of Science, Bangalore 560 012; Fax: 80-3341683; e-mail: madhav@ces.iisc.ernet.in.

APPENDIX 1

Indian Myna

Acridotheres tristis (Class Aves, Order Passeriformes, Family Sturnidae).

Size: 23 cm in length, about 110 gm in weight, a little smaller than a dove, bigger than a bulbul.

Field character: With its plump body, short tail and straight, sharp bill, the Indian Myna is a characteristic feature of Indian life. It is dark brown in colour with a glossy black head and bright yellow legs, bill and a naked patch below and behind eye. When in flight a white bar opens out on the wing; its tail is also bordered with white. Males and females are indistinguishable, the young are a little duller in colour with the heads ashy brown rather than black.

Related species. Indian Myna most resembles the Jungle Myna (*Acridotheres fuscus*) which lacks the yellow patch of skin behind the eye, is greyer in colour and has a little tuft of black feathers at the base of its bill on the forehead. The Bank Myna (*Acridotheres ginginianus*) is slightly smaller and pale bluish grey in colour, with a brick red patch of naked skin below and behind the eye.

Habits. Indian Myna follows people everywhere in the country, quick to colonize even far out in the desert. It is to be seen in town and villages, fields and gardens, sometimes walking after cattle, other times hunting insects on its own. It has a direct, business like flight in the air and a parade step on the ground. Mynas go in pairs or small parties, chattering a great deal. They sleep in large aggregations at communal roosts in large leafy trees, coconut groves, sugarcane fields, or in warehouses or railway stations. Such communal roosts are often mixed with those of crows, sparrows, parakeets or rosy pastors.

Nesting. The breeding season is primarily between April and July, but may commence as early as mid-January in Kerala and extend to September in parts of the country. Mynas nest in holes in trees or in walls and roofs of buildings. Usually there is considerable compe-

tition for nesting sites with violent fights between members of prospective pairs. Each partner grapples with its opposite number in a noisy rough and tumble, often dropping to ground. Mynas generally raise two successive broods over the breeding season laying clutches of 4 or 5 blue eggs.

Food. Indian Mynas have a broad range of diet, chiefly fruit, grain, insect and grubs but also small animals like baby mice, lizards and crabs and kitchen scraps from garbage dumps. They are also fond of nectar from bird flowers like silk cotton.

Distribution. Indian Mynas are resident, staying in a given locality year after year, probably coming to the same communal roost evening after evening. They occur throughout the subcontinent including Pakistan, Bangladesh, Nepal, Bhutan and Sri Lanka, going up to 3000 m in Himalayas. They have also been introduced to Andaman, Nicobars and Lakshadweep, as well as other parts of the world such as New Zealand.

Human significance. Indian Mynas are a companion of man all over the country amusing people with their chirpy chatter. To an extent they damage crops and orchards, but also help by destroying insects.

Population assessment. Indian Mynas are quite conspicuous and may be easily recorded on bird counts along straight transects. Their large noisy communal roosts with several hundred to thousands of birds may also be located and mapped, and birds counted fairly accurately as they gather at the roosts just before the sunset in the evenings. It is also possible to locate their nests and estimate their breeding populations in a given area.

Suggestions for student projects

- (1) Mapping of communal roosts of mynas, crows, parakeets and populations censuses; (2) Role of mynas in pollination of trees like silk cotton and coral trees; (3) Role of mynas as pests of crops like jowar; (4) Biological clock of Mynas in terms of time at which they return to the roosts in the evening; (5) Nesting success of Mynas; (6) Variety of calls used by Mynas in different situations.

Local names: Desi myna (Hindi); Hor (Kashmiri); Salik, Bhat salik (Bengali); Salik sorai, Salika, Ghor salika (Assamese); Dao myna (Cachari); Bemni, Saloo (Chota Nagpur); Gulgul (Madhya Pradesh); Shale, Salonki (Marathi); Kabar (Gujarati); Gorwantera (Kannada); Nahanavai (Tamil); Goranka (Telugu); Kavalamkili, Matatta (Malayalam).

Common mechanism of secretory diarrhoea

Nirmal Kumar Ganguly and Tanvir Kaur

Department of Experimental Medicine and Biotechnology, Postgraduate Institute of Medical Education and Research, Chandigarh 160 012, India

The studies of intestinal electrolyte processes have eluded the attempts to identify the common mechanism involved in secretory type of diarrhoea. The pathogenesis of secretory diarrhoea involves the coupled interactions of Ca^{2+} , PI, PKC, PGs, intramural nerves and cholinergic muscarinic receptor activation. These interactions may result in increase in intracellular Ca^{2+} levels. The increased Ca^{2+} may thus serve an important intracellular mediator involved in the stimulation of intestinal fluid secretion.

THE worldwide impact of acute infectious diarrhoeal diseases is immense, with an estimated 3–5 billion cases per year, resulting in 3–5 million deaths each year¹. A survey reported more than 3 million deaths each year due to diarrhoea². Eighty per cent of these deaths occur in children below two years of age³. It is estimated that the children less than two years of age in developing countries suffer 6–10 episodes of diarrhoea per year, thus approximately 17% of their life in this age group is spent with diarrhoea⁴. A close scrutiny of facts and figures available from National and International sources indicates that first two years of life of a child born in India continues to be crucial from health point of view. It has been estimated that approximately 3 million children die before completion of one year and one million die before attaining childhood every year and these deaths in one way or other are related to diarrhoeal diseases and their effects⁵.

Infectious diarrhoea is generally secretory in nature and can result from bacterial, viral and parasitic infections. The bacteria commonly implicated in the etiology of diarrhoea include conventional enteropathogens like *Shigella*, *Salmonella*, enteropathogenic *E. coli* (EPEC), *Vibrio cholerae* and new enterotoxigenic *E. coli* (ETEC), enteroinvasive *E. coli* (EIEC), enteroaggregative *E. coli* (EAEC), *Yersinia*, *Aeromonas*, campylobacter and recently isolated *Vibrio* 0139 synonym Bengal^{6–9}.

The understanding of underlying pathophysiological mechanisms of acute secretory diarrhoea is growing steadily, now thanks to the intense research interest in the physiology of intestinal electrolyte transport. Considerable insights have been obtained with respect to normal cellular mechanisms of ion transport, though the studies of intestinal electrolyte transport are complicated by several factors (Table 1).

Structural basis for intestinal electrolyte transport

The epithelium of small intestine is located at the interfacial surface, the intestinal lumen is in continuity with external environment. The material absorbed from lumen must first traverse this epithelium to gain access to mucosal blood and lymph vessels.

Structural organization of mucosa of small intestine

The luminal surface of small intestine is so organized that surface area is greatly amplified. Numerous microscopic mucosal villi increase the absorptive surface some seven to 14-fold¹⁰. Depending on the mammalian species and portion of small intestine, villus height and shape vary. Diseases that affect the mucosal function often perturb normal villus structure, thus affecting absorptive surface of small intestine¹¹.

The intestinal mucosa is divided into three distinct layers (Figure 1). The deepest is the muscularis mucosa that separates mucosa from submucosa. Its contractile properties help in the movement of villi and emptying of crypt luminal contents¹². The lamina propria is the middle mucosal layer, which is bounded above by epithelium and below by muscularis mucosa. The lamina contains eosinophils, mast cells, fibroblasts, unmyelinated nerve fibres, blood and lymph vessels. The lamina propria provides support to intestinal epithelial cells and also contains blood vessels that nourish the epithelium. The third layer of intestinal mucosa constitutes a continuous sheet of epithelial cells which line the villi and crypts. The crypt epithelium is composed of undifferentiated cells, mucus secreting goblet cells, endocrine

3. Presence of multiple cell types.
4. Structural heterogeneity of epithelial cells.

Figure 1. Functional morphology of mucosa of small intestine.

epithelial cells, tuft cells and Paneth cells with secretory granules. The epithelium lining the villi contains absorptive cells, termed as enterocytes, mucus secreting goblet cells, few endocrine epithelial cells, rare caveolated cells, cup cells. Additionally, a specialized epithelial cell, the M cell overlies the apex of Peyer's patches.

The functions of crypt epithelium include epithelial cell renewal, secretion into crypt lumen, electrolyte and water secretion and endocrine secretion both into the lamina propria and into the lumen. The major known function of villus epithelium is absorption of nutrients¹².

Cellular mechanisms of ion transport

Na^+ and Cl^- together are by far the major ions of fluid transported during absorption or secretion by small intestine. Na^+ , in particular, plays a central role in the energetics of the intestinal absorption via the transcellular route. The fluid and electrolyte transported depend upon the net effect of absorptive and secretory processes.

Na^+ absorption mainly occurs by three mechanisms (Table 2). The driving force for Na^+ entry is the hydrolysis of ATP catalysed by Na^+ , K^+ -ATPase located at basolateral membrane of enterocytes¹³. This pump exchanges Na^+ out of K^+ in, thus establishing a steep electrochemical gradient for Na^+ entry from lumen (Figure 2). The small intestine of most mammals also possesses a secretory mechanism¹⁴, which normally functions at a low basal level (Table 2). Previous findings support a distribution of secretory function to the crypt cells^{15,16}. Recently, it has been demonstrated that crypts also

absorb fluid and Cl^- secretion occurs in presence of intracellular or extracellular messengers¹⁷.

The mechanisms of electrolyte transport differ in various segments of mammalian intestine. In jejunum, Na^+ entry occurs by (i) Na^+/H^+ exchange, (ii) Na^+ substrate cotransport, (iii) $\text{Na}^+-\text{PO}_4^-$ and $\text{Na}^+-\text{SO}_4^{2-}$ co-transport but active Cl^- absorption does not occur, there is no evidence of direct linking of Na^+ and Cl^- transport, and no $\text{Cl}^-/\text{HCO}_3^-$ or Cl^-/OH^- exchanger¹⁸. In mammalian ileum, Na^+ and Cl^- transport are linked and Na-substrate mechanism is less prominent¹⁹. The mammalian distal colon demonstrates amiloride sensitive Na^+ absorption pathway whereas proximal colon possess a coupled NaCl transport mechanism²⁰.

Pathophysiological mechanisms in diarrhoeal diseases

Cyclic nucleotides

Cyclic nucleotides stimulate intestinal secretion by three potential mechanisms: (i) altered activity of ion trans-

Figure 2. Regulation of intestinal secretion by extracellular mediators and intracellular messengers.

porters, (ii) modulation of tight junctions, and (iii) increase in intracellular calcium levels.

The elevation of cAMP or cGMP levels in intestinal epithelial cells stimulates active chloride secretion by inhibiting electroneutral NaCl absorption in intestinal epithelium²¹. Cyclic AMP acts via stimulation of A kinase with direct phosphorylation and activation of the major chloride channel identified in intestinal epithelial cells, the cystic fibrosis transmembrane conductance regulator (CFTR)²². Second, cyclic AMP regulates intestinal epithelial cell secretion via effects on cytoskeletal proteins. The chloride secretory response to cAMP is dependent on microtubules²³. Further, the apical membrane recruitment of CFTR in T84 cells in response to cyclic AMP is dependent on microtubules but not calcium or F (filamentous) actin²⁴. The mechanism by which activation of cAMP reorganizes F actin is not known. Besides its effect on ion transporters, the study on CT-treated animal tissues, *Campylobacter jejuni* and *Salmonella typhimurium* heat labile toxin suggest that cyclic AMP potentially contributes to intestinal secretion²⁵⁻²⁷.

Lastly, cyclic AMP-dependent agonists stimulate increases in intracellular calcium (Ca^{2+})_i in T84 intestinal epithelial cells. The cAMP-mediated increase in (Ca^{2+})_i occurs via a pathway (Figure 2) distinct from that mediated by inositol triphosphate (IP_3) or protein kinase C (PKC)^{28,29}.

Intracellular calcium

There are several potential mechanisms by which ele-

vation in (Ca^{2+})_i levels stimulates a net intestinal secretion. The elevation of (Ca^{2+})_i levels alters the regulation of several ion-transporting proteins. The increased (Ca^{2+})_i may activate calmodulin-dependent protein kinases (Ca-CaM) or calcium-dependent protein kinase (PKC)³⁰. These activated kinases may phosphorylate membrane proteins that affect the activity of apical membrane Na^+/H^+ exchanger (Figure 2) resulting the decreased Na^+ absorption³¹. Secondly, Ca-CaM dependent protein kinases and PKC may activate CFTR³². Undoubtedly, elevated calcium is enough signal to stimulate chloride secretion in intestinal epithelial cells in the absence of additional second messengers. The previous studies based on evaluating the role of calcium in the presence of its agonists and antagonists suggest its involvement in pathogenesis of many diarrhoeagenic organisms^{26,33-36}. Additionally, calcium has been known to regulate tight junctions, suggesting that changes in (Ca^{2+})_i levels modulate the intestinal permeability and contribute to intestinal secretion³⁷.

Protein kinase C

The PKC family consists of multiple isoenzymes that differ from each other in one way or other³⁸. Specific isoforms of PKC are present in various intestinal cell types. The metabolism of phosphatidyl inositol by phospholipase C (PLC) results in generation of IP_3 and diacylglycerol (DAG). IP_3 releases calcium from intracellular calcium stores whereas DAG activates PKC. The role of PKC activation in stimulating intestinal secretion has been examined by use of activators and inhibitors of PKC with help of Ussing chambers^{26,35,39}. Besides causing intestinal secretion, PKC activation also leads to disassembly of intestinal epithelial cell cytoskeleton and modulation of tight junction⁴⁰. Thus it suggests that PKC activation may contribute to intestinal secretion through direct effects on ion transporters as well as through regulation of paracellular transport pathway.

Phospholipases

The activation of phospholipases leads to changes in intracellular mediators which regulate transport of fluid and electrolytes. The most studied examples are (i) release of arachidonic acid metabolites by the activation of PLA_2 and (ii) release of intracellular calcium through activation of PLC. Activation of PLA_2 leads to the release of AA metabolites, viz. prostaglandins (cyclooxygenase pathway products) and leukotrienes (lipoxygenase pathway products). Certain prostaglandins and leukotrienes may serve to amplify the secretory response for example, prostaglandin I_2 (PGI_2) can activate enteric nervous system and leukotriene B4 stimulates the

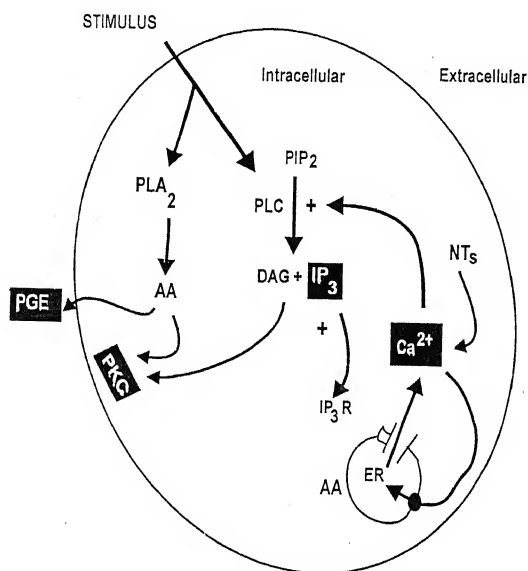

Figure 3. Proposed pathophysiological mechanism(s) involved in secretory diarrhoea.

recruitment of PMNs, leading to an inflammatory response in intestine. Activation of PKC regulates ion transport through the release of calcium and PKC activators as summarized above⁴¹. Recently, additional signalling pathways that involve the activation of PLD and phosphatidyl specific PLC have been identified^{38,42}. These pathways lead to the release of lipid metabolites (e.g. diacyl glycerol and phosphatidic acid) that regulate specific cell functions.

Enteric nervous system

Considerable evidence exists regarding the involvement of one or more components of enteric nervous system in secretory responses to bacterial toxins⁴³. Neural pathways appear to involve villus to crypt neural reflexes. The neuropeptides (Figure 1) such as those secreting substance P, 5-HT, vasoactive intestinal peptide (VIP)^{44,45} and acetylcholine have been implicated in the secretory responses to *C. difficile* toxin A, CT, *E. coli* heat stable enterotoxins (STa and STb) and Shigella toxin^{36,46-48}. Several bacterial pathogens and/or their toxins have been shown to alter intestinal myoelectric patterns. These include CT, *E. coli* STa, wild type and recombinant *V. cholerae* strains, Shigella toxin and various classes of *E. coli* [e.g. enteropathogenic *E. coli* (EPEC), ETEC and enteroinvasive *E. coli* (EIEC)]^{36,49-51}.

Summary

Diarrhoea is one of the major causes of mortality during infancy and early childhood in developing countries.

The underlying pathophysiological mechanisms in secretory diarrhoea involves the complex interaction of several biochemical pathways. Calcium may be located at the cross over point of various pathways involving PKC, prostaglandins, intramural nerves and cyclic nucleotides. Increased calcium (either through extracellular calcium or release of calcium from intracellular stores) may activate PKC by its translocation from cytosolic to membrane, thereby phosphorylate membrane proteins. The sequence of interaction leading to an increase in intracellular Ca^{2+} appears central to the control of diarrhoea modulating ion transport through activation of protein kinase C (Figure 3).

Molecular biology and biotechnology of higher plant nitrate reductases

H. S. Srivastava and Niharika Shankar

Department of Plant Science, Rohilkhand University, Bareilly 243 006, India

Nitrate reductase (NR) catalysing the reduction of nitrate to nitrite is the first and rate limiting enzyme in the assimilation of nitrate by the plants. At least two of its isoforms; a NADH specific and a NAD(P)H bispecific have been characterized. In this article, the physico-chemical properties of NADH specific isoform, which is the principal isoform of nitrate assimilation, have been described. The properties of cloned genes and the production of transgenic plants with altered NR activity, and mechanism of induction of NR by nitrate and cytokinins, repression by glutamine and post-translational modification of NR protein through reversible phosphorylation by light-dark transitions have also been accounted for. The characterization of NAD(P)H : NR gene and some regulatory aspects of this isoform have also been described. The article demonstrates that it is possible to produce mutants and transgenics with altered structure and function of NR, with an ultimate aim to affect qualitative and quantitative improvement of crop plants.

NITRATE reductase (NR) catalysing the reduction of nitrate to nitrite is the first enzyme in the assimilation of nitrate

by plants. The activity is considered to be the rate-limiting step in nitrate assimilation, which is often positively correlated with the total protein and nitrogen contents and sometimes also with the overall productivity of the plants¹. Three isoforms of this enzyme have been described from soybean², viz. (i) A nitrate inducible NADH : NR (E.C.1.6.6.1) with a pH optimum of 7.5, (ii) A constitutive or inducible bispecific NAD(P)H : NR (E.C.1.6.6.2) with a optimum pH of 6.5, and (iii) A constitutive NADH : NR (E.C. number not yet assigned), with a pH optimum of 6.5. The inducible NADH : NR and the bispecific NAD(P)H : NR are usually found in close association with various plants and perhaps both are involved in nitrate assimilation. The NAD(P)H : NR however, is considered to be associated with some other functions also, such as with the transport of nitrate across the membranes and with the dissimilatory release of oxygen in anaerobic environment³. The evidences for these alternate functions are yet to be known, although the observation that NAD(P)H : NR isoform was localized principally on the plasma membrane⁴ is a strong indicator of its role in nitrate acquisition and transport. NR has been used as a biotechnological tool/product also. Mellor

*et al.*⁵ have evolved a bioreactor that employs immobilized NR from maize along with some bacterial enzymes to reduce nitrate to nitrogen gas. The bioreactor may be used for reducing nitrate contamination of groundwater which is otherwise rendered unfit for human consumption because of toxic nitrate contamination. Similarly, the accumulation of toxic levels of nitrate in crop plants can also be restricted by *in vivo* regulation of NR through genetic manipulations. For example, Quillere *et al.*⁶ have demonstrated that genetically transformed *Nicotiana plumbaginifolia* plants with a 25 to 150% higher NR activity have a 32 to 47% lower nitrate contents as compared to wild type controls. Thus, the interest in the study of NR has been generated with different objectives.

Physico-chemical nature of the enzyme

Although the NR from higher plants was characterized for the first time in the early fifties⁷ its purification could be achieved only in the seventies^{8,9}, primarily because the enzyme is very unstable and it requires special care for extraction, isolation and purification. The *in vivo* experiment showed that the protein is short lived with a half life of only 3 to 5 hours¹⁰. The enzyme has been purified from a variety of species including barley, maize, soybean, spinach, squash, tobacco, etc. by affinity chromatography and electrophoresis. Monoclonal antibodies of the enzyme have been raised^{11,12}. Nitrate reductase (E.C. 1.6.6.1) from higher plants is a homodimer with each sub unit of 100 to 120 kD molecular mass of 881 (bean) to 926 (spinach) amino acids¹³. In each sub unit, acidic amino acids are more abundant than the basic ones; the isoelectric point of a squash NR has been determined¹⁴ to be 5.7. There are 9 to 19 cysteine residues in each sub unit and the two sub units are linked through at least three disulphide bonds of cysteine residues¹⁵. Each sub unit contains at least three prosthetic groups, FAD, heme (cytochrome b_{557}) and Mo-pterin (Mo-CO). The NADH/NADPH binding region and the FAD domain are at C-terminal while Mo-CO is at N-terminal of the polypeptide. The cytochrome heme domain occupies a central part in the polypeptide. The Mo-pterin domain is a complex of Mo atom linked to a pterin (a heterocyclic compound) molecule via a thiol group (Figure 1). The three domains of the polypeptide are apparently linked through two hinges; hinge I (HI) between Mo-Co and cytochrome and hinge II (HII) between the cytochrome and the FAD. As described later HI plays an important role in the enzyme modulation by phosphorylation-dephosphorylation¹⁶. The three regions of the polypeptide can be separated by treatment of the enzyme with appropriate proteases. Three separated domains show partial activities

of the enzyme. The Mo-Co domain is believed to be involved in the dimerization of sub units.

The reductant used in the reduction of nitrate to nitrite is NADH. The bispecific NAD(P)H : NR however, uses either NADH or NADPH; the preference being for the latter. The initial acceptor of the electron from NADH/NADPH is FAD of the enzyme. Then the electron flows through cytochrome b_{557} site to Mo-pterin site in the enzyme and ultimately to the nitrate, which is reduced to nitrite;

Active site amino acid mapping of the enzyme has been done by using appropriate enzyme inhibitors. Histidine¹⁷ and arginine & lysine¹⁸ are involved in NADH binding with the enzyme. A difference in the amino acid sequence between bispecific NAD(P)H : NR of birch (*Betula pendula*) and that of monospecific NADH : NR of many species have been found in the FAD domain of the enzyme¹⁹. Arginine residues are involved in the catalytic function of FAD and Mo-CO domain²⁰. Specific inhibitors binding these amino acids block the flow of electrons from NADH to nitrate and hence the catalytic activity of NR. Cysteine also appears to be actively participating in the electron transfer. Dwivedi *et al.*²¹ replaced each of the five cysteine residues of recombinant cytochrome reductase domain from maize leaf NR with other amino acid analogues using site-directed mutagenesis. The enzyme had intact NADH-binding sites but had reduced ferricyanide reductase activity. The authors have concluded that cysteine is essential for a highly efficient catalytic transfer of electrons from pyridine nucleotides to flavins.

Gene cloning and transgenics

Genetic experiments including the study of NR deficient mutants have helped in the identification of genes coding for the synthesis of NR protein. In barley, two structural loci *Nar 1* and *Nar 7* have been identified, which

Figure 1. Diagrammatic representation of the structure of nitrate reductase showing path of electron transfer.

REVIEW ARTICLES

apparently code for inducible NADH:NR and NAD(P)H:NR respectively²². Two genes *NR 1* and *NR 2* have been identified in *Arabidopsis thaliana*²³ and in tobacco²⁴. Zhou *et al.*²⁵ have described the presence of only one gene for NADH:NR in cultivated barley, while two genes in diploid wheat *Triticum monococcum* and in hexaploid wheat *Triticum aestivum*. They have suggested that during evolutionary events NADH:NR gene duplicated before the divergence of wheat and barley and that a deletion resulted in the loss of one NADH:NR gene from cultivated barley.

Both the NADH and NAD(P)H specific NR genes have been now cloned from a variety of species from either genomic library or from c-DNA (Table 1). The complete sequence of the nucleotides is known from *Arabidopsis*, birch (NAD(P)H:NR), barley, bean, rice, tobacco and tomato¹³. The NADH:NR gene is about 3000 to 5000 bp long and contains about one to three introns. The genome of barley NADH:NR is however, longer, about 7300 nucleotides and the NAD(P)H:NR from the same species is 3538 bp with two introns. A

transposable element of about 565 bp in the first exon of NR genome of a NR-deficient mutant (obtained by γ -irradiation) of tobacco has been detected²⁶. It occurs as a single copy in the genome and is apparently lacking in *Lycopersicon* and *Petunia*.

Transgenic tobacco with altered NR activity has been developed²⁷⁻³¹. Constructs carrying the entire or part of the tobacco c-DNA cloned between the promoter and terminator sequence of the 35 S RNA of cauliflower mosaic virus were introduced in tobacco²⁷. A few NR-deficient transgenics were obtained and a few with increased NR m-RNA and NR protein were also obtained. In another attempt, NR deficient tobacco plants were transformed to high NR activity types through the transfer of NR c-DNA with 35 S constitutive promoter from cauliflower mosaic virus²⁸. The transgenics accumulated higher amounts of glutamine and reduced levels of nitrate in their leaves. Transgenic tobacco have helped in visualizing the physiological significance of the inducibility of NR protein by nitrate. The study has shown that the constitutive expression of NR does not influence

Table 1. Some characteristics of nitrate reductase genes cloned from higher plants

Plant species and the organ	Clone	Some characteristics	Reference
A. NADH:NR gene			
<i>Arabidopsis thaliana</i> leaves	Genomic	3829 bp, two introns	83
<i>Cucurbita maxima</i> (squash) cotyledons	c-DNA	2754 bp plus a untranslatable region of 135 nucleotides at 3' end and poly A tail of 16 nucleotides, coding for 918 amino acids	84
<i>Glycine max</i> (soybean) leaves	c-DNA	<i>NR 1</i> : 2661 bp, coding for 886 amino acids <i>NR 2</i> : 2673 bp, coding for 891 amino acids	46
<i>Hordeum vulgare</i> (barley) leaves	Genomic	7300 bp, one large intron of 2700 bp, coding for 915 amino acids	41
<i>Lycopersicon esculentum</i> (tomato) leaves	Genomic	5300 bp, three introns, coding for 911 amino acids	85
<i>Nicotiana tabacum</i> (tobacco) leaves	Genomic	6000 bp, three introns coding for 904 amino acids	86
<i>Oryza sativa</i> (rice) leaves	Genomic	5400 bp, three introns coding for 916 amino acids	87
<i>Phaseolus vulgaris</i> (bean) - roots	Genomic	4600 bp, three introns, coding for 881 amino acids	88
- leaves	Genomic	Four introns, coding for 890 amino acids	89
<i>Spinacea oleracea</i> (spinach) leaves	c-DNA	3284 bp, two introns, coding for 926 amino acids	90
B. NAD(PH):NR gene			
<i>Betula pendula</i> (birch) leaves	c-DNA	3031 bp, coding for 898 amino acids	91
<i>Hordeum vulgare</i> (barley) leaves	Genomic	3538 bp, coding for 891 amino acids	42

the foliar protein and chlorophyll contents, the assimilatory products of nitrate, under any circumstances²⁹. Further, under the conditions of nitrogen deficiency, the NR protein is actively degraded.

Transgenics have also been created with a view to understanding some of the regulatory aspects of NR. Nussaume *et al.*³¹ have transformed a NR deficient tobacco by introducing a full length *Nicotiana* c-DNA with an internal deletion of 168 bp in the 5' end fused to cauliflower mosaic virus 35 S promoter and appropriate termination signals. In transgenic plants expressing this construct, NR activity was restored and normal growth resulted. However, *in vitro* NR activity from these transformants was not modulated by ATP and light. A heterogenous expression system has been developed to examine the regulatory mechanism of NR through phosphorylation-dephosphorylation³². Wild type and mutant forms of NR c-DNA from *Arabidopsis thaliana* have been inserted and expressed in the yeast *Pichia pastoris*. This allowed to produce mutant forms of NR for various regulatory studies. The technology may also be used in the production of plant NR in bulk for X-ray crystallography and other biophysical investigations.

Transcriptional control of NR gene expression

Nitrate reductase is subjected to a multivalent control at gene expression level³³. Some of the regulators of the enzyme are structurally or metabolically related to nitrate, the substrate of the enzyme, or to one of the assimilatory products of nitrate; while others are general regulators of NR and of other enzymes.

Induction by nitrate

Induction of NADH:NR gene has been demonstrated by nitrate, cytokinin and light. Nitrate is the substrate of the enzyme and also a specific inducer of NR activity, a property which has been demonstrated in almost all the investigations¹. Different levels of nitrate are required for optimum induction of NR in different species, which is perhaps linked to the differential rates of uptake and/or mobilization of nitrate to the genomic level¹. When the entire plant or its excised organs are incubated in a nitrate-containing medium, the NR activity in the plant or organ starts increasing after a lag of about 15–45 min and goes on increasing almost linearly until 180–400 min. Thereafter, a steady state level is maintained. However, if nitrate is withdrawn from the medium, the steady state level declines. Further, the linear increase in enzyme activity is abolished in the presence of transcriptional and translational inhibitors. Chemical isolation of RNA, Northern blotting and c-DNA isolation and hybridization experiments performed in a variety of

plant systems have demonstrated that nitrate supply in fact increased the synthesis of m-RNA. For example, in *Cucurbita maxima* (squash) an increased apoprotein synthesis in response to nitrate was linked with the increase in m-RNA³⁴. This increased transcription required intact plastids in the cotyledons³⁵. In barley, when nitrate-starved seedlings were transferred to a nitrate-containing medium, NR m-RNA increased rapidly from essentially zero to high levels within a few hours in both roots and shoots³⁶. In nitrate cultured tobacco and tomato seedlings also, further supply of nitrate increased NR m-RNA, although at relatively slow rate³⁷. In maize roots, the increase in NR activity in response to nitrate is correlated with the increase in NR m-RNA^{38,39}. Transcriptional assays with isolated soybean nuclei also indicate that induction of NR m-RNA is due to *de novo* synthesis of the transcript and not due to reduced RNA degradation.

In a recent study, a nitrate independent transcription of two NR isogenes in androgenic haploid embryos of *Brassica napus* (rape seed) has been demonstrated⁴⁰. However, in the leaf, NR gene expression responds to nitrate supply as in most other systems. This demonstrates the uniqueness of the regulation of NR gene expression in haploid embryogenesis.

The effect of nitrate supply on NAD(P)H:NR has also been examined. In barley, the genes for both NADH:NR and NAD(P)H:NR have been isolated and sequenced^{41,42}. There is a high degree of sequence similarity between the two genes. However, there is a significant divergence at 5' end of the gene and thus it has been possible to differentiate between the m-RNAs of two genes. The divergence also indicates that there was a possibility of differential regulation of the expression of two genes. In soybean, nitrate supply has no effect on NAD(P)H:NR activity although it induces NADH:NR^{2,43}. However, in barley, NADH: and NAD(P)H:NR m-RNAs are at detectable levels in both roots and leaves within 15 to 30 min after exposure of seedling roots to nitrate⁴⁴. Nitrate depletion triggers a rapid decrease in both m-RNAs and in the activities of both the isoforms. It indicates that in barley at least both the genes, *Nar 1* and *Nar 7* coding for NADH:NR and NAD(P)H:NR respectively are under the control of the same promoter/regulator. Vaucheret and Caboche³⁰ by using transgenic *Nicotiana plumbaginifolia* have demonstrated that the promoter for *Nia* gene is specific for the gene. In transgenic plants, the expression of a reporter gene neomycin phosphotransferase driven by a 1.4 kb *Nia* promoter had a negative correlation with the induction of *Nia* gene³⁰. Positive response of NAD(P)H:NR to nitrate supply has been demonstrated in maize also³⁸, although the species has a significant level of constitutive expression also (Shankar and Srivastava, unpublished).

The mechanism of signal transduction in nitrate induction of NADH or NAD(P)H : NR gene is not known. Presumably *cis* acting elements and *trans* acting proteins are involved in the induction. In transgenic tobacco plants containing *Arabidopsis* NR genes, the DNA sequence responsive to nitrate has been identified to be at 5' end, a 238 or a 188 bp sequence in NR 1 or NR 2 genes respectively⁴⁵. The promoter region for the two genes in tobacco, however seems to be larger²⁴.

Regulation by glutamine

Inhibition of NR activity by the addition of glutamine has been demonstrated in many species. That the inhibition is at transcription level has been demonstrated in soybean^{40,46}, tobacco^{47,48}, maize¹⁰ and in cultured spinach cells⁴⁹. The inhibition is partially overcome by the addition of glucose in tobacco leaves⁴⁸. Endogenous glutamine level also seems to be controlling NR gene expression. In tobacco, inhibition of glutamine synthetase enzyme leads to a sharp decline in glutamine level, which resulted in an increased NR m-RNA⁴⁷. In maize seedlings, the root enzyme is more sensitive to exogenously supplied glutamine than the shoot enzyme, which is apparently because of the more sensitive NAD(P)H:NR (primarily a root enzyme) than the NADH:NR³⁹. However NR m-RNA was almost equally inhibited by glutamine in both roots and shoots. Thus, there might be some additional aspect of down regulation of active NR protein formation by the glutamine in the roots.

Induction by cytokinins

Exogenous supply of cytokinins invariably increases NR activity, although the magnitude of increase depends upon the species and the concentration and nature of the cytokinin. Apparently, the endogenous cytokinin level is an important factor in determining the effects of exogenous cytokinins. As with nitrate, cytokinins also appear to be acting at transcription level in inducing NR activity^{50,51}. Adenine or adenosine have no effect on NR activity⁵¹. The induction by cytokinins is usually higher in the presence of nitrate than in its absence⁵², although the two inducers do not seem to be acting synergistically⁵¹. Samuelsson *et al.*⁵¹ have also demonstrated that nitrate supply elevated cytokinin zeatin riboside level in barley roots and shoots. This could determine the influence of externally supplied cytokinin on NR activity in the presence of nitrate. The exact mechanism of induction of transcription by cytokinins is not known. However, Suty *et al.*⁵³ have reported that cytokinin-mediated transcription in tobacco cell suspensions involved m-RNA polyadenylation.

The plant hormone abscissic acid represses NR gene expression in barley, which is partially recovered by equal concentration of benzyladenine⁵⁰. Thus, abscissic acid also might be acting at transcription level. Bueno *et al.*⁵⁴, however, have suggested that kinetin-mediated increase in NR activity in *Cicer areitenum* cotyledons is both through synthesis and activation of the enzyme.

Effect of light and sugars

Light is another factor regulating NR activity in upward direction. Enzyme extracted from the organs of the plants raised in light is several folds more active than those from dark grown. The positive response of light is apparent in non-photosynthetic organs such as roots, endosperm and scutella also⁵⁵. In many systems, the effect of light appears to be at transcription level, although post transcriptional modifications of NR protein by light is also known.

In a study with five-day-old maize seedlings, Lillo⁵⁶ observed a four-fold increase in NR m-RNA level within one hour exposure to light. This was reported to be due to increased transcriptional activity. In another study with maize, Huber *et al.*⁵⁷ also reported a significant increase in leaf NR m-RNA within two hours of illumination of previously darkened seedlings.

It has been often suggested that the light/dark effects on NR activity were responsible for observed diurnal variation in enzyme activity. However, in a few investigations, an increase in NR m-RNA and in NR activity has been observed during the night. This is apparently because sucrose and glucose replace light requirements in the induction of m-RNA as has been reported in *Arabidopsis*²³ and tobacco⁴⁸. In tobacco leaves, fructose also induces transcription of NR m-RNA while ribose or mannitol has no effect⁴⁸. This has led these investigators to believe that up-regulation of NR gene transcription by light is mediated via carbohydrate synthesis in green leaves.

There is also some indication of post transcriptional modification of NR m-RNA in plants. In *Arabidopsis*, the expression of *Nia 2* gene shows circadian oscillations⁵⁸. The m-RNA accumulation also shows rhythm even up to five days in continuous darkness after the plants have been grown in light/dark cycle.

Translational control

The modification of NR protein synthesis at translation level has not been demonstrated although it is often assumed that many factors controlling transcription have effect on translation also. There is some circumstantial evidence for translational control of NR synthesis by oxygen, which is known to inhibit NR activity in oat

leaves⁵⁹. In detached maize leaves, NR activity and NR protein appearance were partially inhibited at 100% oxygen, but the m-RNA levels as measured by leaf NADH:NR c-DNA hybridization tests were the same in air and 100% oxygen-treated leaves⁶⁰.

Post-translational modification of NR protein

Some of the regulators of NR activity have very fast effects, the activity responding the regulator as quickly as in a few minutes. These regulators apparently act through the modulation of NR protein. For example, in spinach leaves, the NR activity decreases rapidly during darkening of the leaves, reaching to about 15% of the control value in only about two minutes⁶¹.

The processing of the nascent NR protein into an active NR molecule itself is a step which is affected by some regulators. Molybdenum cofactor is inserted in the NR protein after it has been fully synthesized. In the absence of Mo, no active NR is formed. Tungsten, a metal classified with Cr, Mo and U in the periodic table competes with Mo, and produces a NR protein which is inactive in nitrate reduction⁶².

Reversible phosphorylation

The reversible phosphorylation of NR protein appears to be the most important mechanism of enzyme regulation in both prokaryotes and eukaryotes. It allows a fast modulation of enzymic protein with the change in its micro-environment. For NR, it has been now demonstrated that phosphorylation-dephosphorylation was involved in dark-light inactivation/activation of the enzyme. Upon transition of plant or plant organs from darkness to light, the NR protein is in dephosphorylated (active) form, whereas phosphorylation of specific serine residues is increased on transition to darkness^{63,64}. The phosphorylation is catalysed by specific protein kinases; two protein kinases, NR:PK I and NR:PK II have been isolated from spinach leaves⁶⁵. NR:PK I has a broader specificity and can phosphorylate sucrose phosphate synthase also. NR:PK II however, which has an apparent *Mr* of 160 kD, is specific for NR only. The NR specific PK (PK II) is a Ca^{2+} -dependent and uses ATP as phosphorylation substrate. *In vitro* experiments have revealed that γ -³²P of ATP is incorporated into NR protein from *Brassica campestris*⁶⁶. Analysis of phosphoamino acids in phosphorylated NR from *Arabidopsis* has revealed that serine at position 308 in Mo-Co domain is required for phosphorylation of NR and also apparently for normal activity of the enzyme⁶⁷. When serine is replaced by aspartic acid, both the processes, the normal activity and the phosphorylation of the NR protein are disrupted. However, in spinach, phosphorylation of Ser-

543 has been demonstrated by using recombinant DNA fragments²⁴. In another investigation with *Arabidopsis* NR expressed in *Pichia pastoris*, Ser-534 is shown to be phosphorylated³². In both these systems, Ser-543 or Ser-534 are located in hinge I region and occupy equivalent position in the polypeptide. Further, transgenic tobacco containing a 168 bp deletion at 5' end of the *Nia* are insensitive to modulation by ATP or light³¹. However, it is not clear whether this deletion results in the deletion of the critical serine residue or in some other kind of amino acid changes. The phosphorylation of NR protein in dark is apparently not itself enough for complete enzyme inactivation. The inhibition in fact is affected by another protein known as inhibitor protein (IP; *Mr* 110 kD) which in the presence of Mg binds to the phosphorylated NR and inactivates it^{68,69} (Figure 2). Magnesium application is known to inhibit *in vitro* NADH:NR activity but not the methyl viologen activity⁷⁰. Apparently, the electron flow from NADH to the flavin is inhibited in the presence of Mg. The NR-inhibiting protein from spinach has been characterized by Yoshimura *et al.*⁷¹, which is a dimer with sub unit *Mr* of approximately 53 kD.

Divalent cations Ca^{2+} and Mg^{2+} are key regulators of NR activity through their involvement as cofactors for either protein kinases or inhibitor protein. The inhibition of NR activity by these ions as reported in many species appears to be a hysteric property, at least for the enzyme

Figure 2. Mechanism of reversible phosphorylation of nitrate reductase during dark-light transition (IP = inhibitor protein; PK = protein kinase; PP 2A = protein phosphatase 2A).

REVIEW ARTICLES

from spinach leaves⁷². The enzyme extracted from darkened leaves is in low activity or low affinity form, while the one extracted from illuminated leaves is in high activity or in high affinity form^{72,73}. When extracted from darkened leaves, the enzyme which is in low affinity form is inhibited more strongly by Ca^{2+} and Mg^{2+} , than when extracted from illuminated leaves, where the enzyme is in high affinity form. Little inhibition of enzyme is seen when it is converted to high affinity form by preincubation of the low affinity enzyme preparation with the substrate⁷² or with Pi, 5'AMP and FAD⁷³. The low affinity form has a optimum pH of 7.5, while high affinity form has a optimum pH of 7.8 (ref. 74). The conversion of enzyme to a high affinity form in light apparently involves dephosphorylation of the enzyme protein by phosphatases. In *in vivo* experiments, the reactivation of inactivated (darkened plants) enzyme is prevented by okadaic acid, an inhibitor of certain phosphatases⁷⁵. Further, in *in vitro* experiments, the NR that had been inactivated in the presence of NR kinase, ATP-Mg and inhibitor protein could be reactivated either by dephosphorylation with protein phosphatase 2A or by dissociation of inhibitor protein from NR⁶⁹.

Signal transduction

Attempts have been made to trace the path of signal transduction in NR regulation by light at least. Light signals for NR induction is apparently received by the phytochrome, at least in etiolated plants^{36,58,76}. Sopory and his associates have suggested the involvement of Ca^{2+} and phosphoinositide cycle as second messengers in the transduction of signal from active phytochrome to NR gene expression⁷⁷⁻⁷⁹. In fact, Raguram and Sopory⁸⁰ have demonstrated that the involvement of phosphoinositide cycle and protein phosphorylation by protein kinase type enzyme, is a common strategy in signal transduction through phytochromes. Bergarche *et al.*⁸¹ have also demonstrated that the phytochrome was effective only when free Ca^{2+} was available. In addition, a signal originating from chloroplasts is also required for the control of NR expression by light, in green tissues²⁸.

Recently, the presence of a specific receptor for nitrate has been suggested in the plasma membrane, which besides binding with the nitrate may also bind with the respiratory inhibitors azide and cyanide⁸². The significance of the binding of the inhibitors is not understood at the moment.

Concluding remarks

Significant achievements have been made in the study

of the molecular biology of higher plant NR during the last 10 years or so. The story is not complete; the mysteries are absorbing and the prospects of deep inquisitiveness and indulgence are inevitable. The successful creation of transgenics with altered NR structure and function have opened up the possibilities of manipulating this enzyme for qualitative and quantitative improvement of crops and also for the reduction of nitrate contamination of food and feed products. A commercially viable technology for using NR preparation for reduction of nitrate contamination of ground water is to be developed; the probabilities are excellent.

3' Non-templated 'A' addition by *Taq* DNA polymerase: An advantage in the construction of single and double mutants

J. Jagath-Reddy, N. Appaji Rao, H. S. Savithri

Department of Biochemistry, Indian Institute of Science, Bangalore 560 012, India

The 3'-end non-templated 'A' addition by *Taq* DNA polymerase has been described as a disadvantage in the generation of site-specific mutants as this 'A'

leads to a unplanned second mutation. Here we demonstrate the utility of this 3' non-templated 'A' addition in the simultaneous construction of single and double mutants of serine hydroxymethyltransferase.

Site-directed mutagenesis (SDM) has been widely used for research in molecular biology and protein engineering. Several methods for SDM using polymerase chain reaction (PCR) have been described¹⁻⁸. Megaprimer method is one of the most rapid and universal, in which one mutagenic primer and two universal flanking primers are required. A possible problem associated with this method is the addition of an adenosine residue at 3'

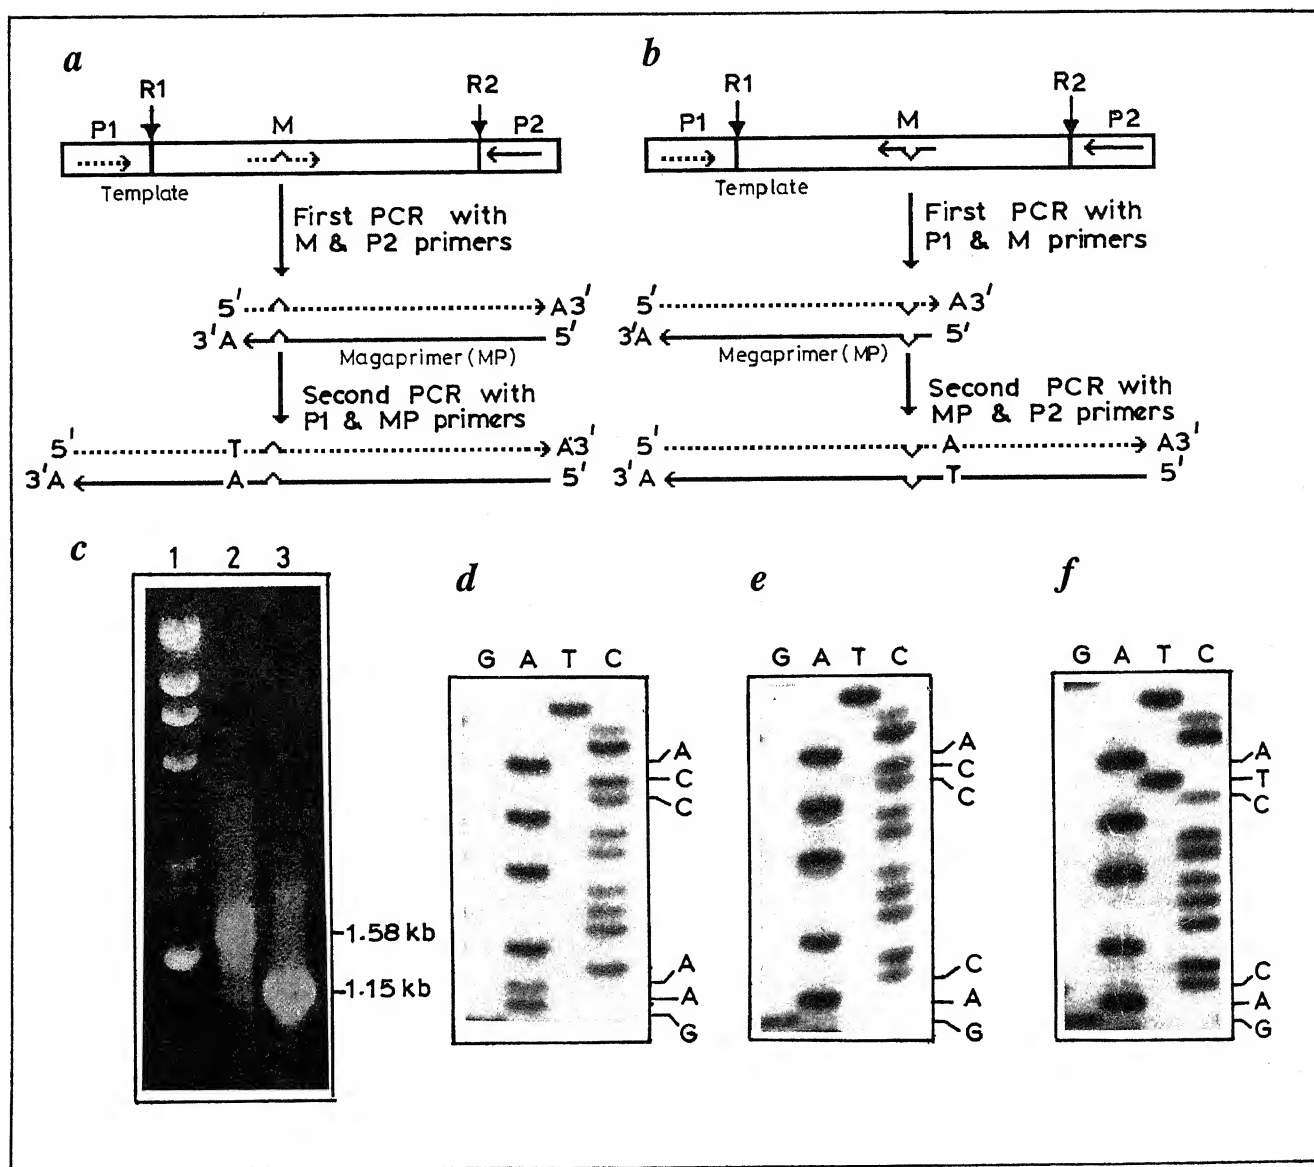

Figure 1 a-c. A megaprimer method for the construction of single and double mutants. *a, b*, Schematic diagram for the construction of single and double mutants. The coding strand of PCR product is shown as dotted lines and non-coding strand in solid lines. Sense and antisense primers are shown as (...) and (←). *c*, Agarose gel with lane 1. Lambda Hind III/pUC 19 Hind I marker, lane 2. Final PCR product with expected size of 1.58 kb and lane 3. First PCR product (megaprimer) with an expected size of 1.15 kb. Part of sequencing gel confirming *d*, wild type SHMT sequence; *e*, single mutant (AAG → CAG); *f*, double mutant (AAG → CAG and ACC → ATC).

end of the PCR product by template independent terminal transferase activity of *Taq* DNA polymerase⁹, resulting in an unplanned mutation. Here we report an advantage of this 3' non-templated 'A' residue addition in the generation of specific double mutants using a single mutagenic primer.

As shown in Figure 1 a, if a sense mutant primer is used it will anneal to the non coding strand and an 'A' residue will be added to the 3' end of the PCR product during first PCR. This addition of an 'A' residue will eventually lead to a 'T' substitution in the coding strand upstream of the desired mutation. In contrast when an antisense primer is used, it will lead to an 'A' substitution in the coding strand downstream of the desired mutation (Figure 1 b). As apparent from the Table 1, by a proper design of the mutant oligos, double mutants can be obtained with varying amino acid substitutions as described in this study.

In our studies aimed at understanding the structure-function relationship of serine hydroxymethyltransferase (SHMT) from sheep liver, we were interested in the construction of single and double mutants of the SHMT gene. The protocol for this purpose involved, the first PCR amplification carried out in a total volume of 100 µl containing 75 pmoles of the 19-mer reverse universal primer (P2) and 20-mer mutagenic primer (M) (H148N mutagenic primer: 5' G GAT GGG GGC AAC CTG CTG A 3' or K257Q mutagenic primer: 5' C ACC ACC CAC CAG ACC CTG C 3') (Bangalore Genei Pvt Ltd., Bangalore, India), 2.5 units of *Taq* DNA polymerase (United States Biochemical, Cleveland, OH, USA), 0.2 mM deoxyribonucleoside triphosphate (dNTP, Amersham International plc, Buckinghamshire, UK), 2 mM MgCl₂, 50 ng of DNA template (pUCSH) and the buffer provided with the enzyme at 1x concentration. The reactions were

amplified in a thermal cycler (COY Tempecycler II Model 110S, COY Laboratory Products Inc., Ann Arbor, MI, USA) with the initial 4 min denaturation at 94°C then for 30 cycles with 1 min denaturation (94°C), 1 min annealing (50°C), 1 min 30 sec elongation (72°C) followed by 10 min elongation at 72°C. Samples were analysed on 1x TAE agarose gel (Figure 1 c). PCR products were purified as described by low-melting temperature-agarose method¹⁰. Purified PCR products were quantitated on agarose gel by ethidium bromide fluorescence. A second PCR was set up using the conditions similar to those described above with 25 pmoles P1 (internal primer for SHMT gene: 5'T ATG GCA GCT CCA GTC AAC 3') (National Biosciences, Plymouth, MN, USA) and 1 µg of purified first PCR product as primers and 50 ng of pETSH DNA as template. We have used different templates in the two PCR amplifications, i.e. pUCSH in the first PCR (1.2 kb SHMT cDNA clone lacking 227 bp at 5' end in pUC19 vector) and pETSH in the second PCR (1.45 kb full length SHMT cDNA clone in pET 3c vector)¹¹ to obtain convenient restriction sites in the final PCR product. However, the same template can be used for both the PCRs. The final PCR product was gel purified, digested with KpnI, BamHI and ligated with KpnI, BamHI digested pUC 19. The ligation mixture was used to transform *Escherichia coli* DH5α cells. The mutations were confirmed by dideoxy double-stranded DNA sequencing¹² using sequence version 2.0 DNA sequencing kit (United States Biochemical).

In the design of a mutagenic primer, a Lys (AAG) residue has been changed to a Gln (CAG). The primer has been designed to begin with a cytosine (C) base corresponding to 3rd base of Thr (ACC) which is 3 amino acids upstream to this Lys in the SHMT gene. Since this is a sense mutant primer, a 'T' will be

Table 1. Anticipated amino acid changes due to 3' non-templated 'A' addition by *Taq* DNA polymerase

Amino acids	Codon	1st base		2nd base		3rd base	
		T	A	T	A	T	A
Phe/Leu	TTN	—	Ile/Met	—	Tyr/*	Phe	Leu
Ser	TCN	—	Thr	Phe/Leu	Tyr/*	—	—
Tyr/*	TAN	—	Asn/Lys	Phe/Leu	—	Tyr	*
Cys/*/Trp	TGN	—	Ser/Arg	Phe/Leu	Tyr/*	Cys	*
Leu	CTN	Phe/Leu	Ile/Met	—	His/Gln	—	—
Pro	CCN	Ser	Thr	Leu	His/Gln	—	—
His/Gln	CAN	Tyr/*	Asn/Lys	Leu	—	His	Gln
Arg	CGN	Cys/*/Trp	Ser/Arg	Leu	His/Gln	—	—
Ile/Met	ATN	Phe/Leu	—	—	Asn/Lys	Ile	Ile
Thr	ACN	Ser	—	Ile/Met	Asn/Lys	—	—
Asn/Lys	AAN	Tyr/*	—	Ile/Met	—	Asn	Lys
Ser/Arg	AGN	Cys/*/Trp	—	Ile/Met	Asn/Lys	Ser	Arg
Val	GTN	Phe/Leu	Ile/Met	—	Asp/Glu	—	—
Ala	GCN	Ser	Thr	Val	Asp/Glu	—	—
Asp/Glu	GAN	Tyr/*	Asn/Lys	Val	—	Asp	Glu
Gly	GGN	Cys/*/Trp	Ser/Arg	Val	Asp/Glu	—	—

The table shows the possible amino acid changes which could arise by 'T' or 'A' substitution in the coding strand at 1st, 2nd or 3rd base of a given amino acid(s). Stop codon is shown as (*), (—) is shown for no change in the amino acid.

substituted for 'C' (i.e. 2nd position in the ACC codon) which will result in the mutation Thr → Ile (ATC), leading to the generation of a double mutant (Lys → Gln and Thr → Ile). Similarly, 'T' to 'C' substitution was observed in the case of *nisA* gene⁶. If the primer starts from the second base of the codon (ACC) then the 'T' to 'A' substitution will take place at first base of the codon resulting in the mutation Thr → Ser (TCC) (see Table 1). Thus by a proper design of mutagenic primers, specific double mutants can be generated. Some DNA molecules will be left without 3' non-templated 'A' addition which would lead to a single mutant (Lys → Gln). We have sequenced 4 clones in which 2 of them are double mutants (Ile-Thr-Thr-His-Gln) and 2 of them are single mutants (Thr-Thr-Thr-His-Gln) (Figure 1 d). Similarly, we have constructed single and double mutants for the SHMT where Pro-Asp-Gly-Gly-His (wild type) had been converted to Pro-Asp-Gly-Gly-Asn (single mutant) and Leu-Asp-Gly-Gly-Asn (double mutant). In this case, we have sequenced 13 clones in which one of them is single and 12 are double mutants. These mutants were expressed and found to be present in the soluble fraction (Jagath-Reddy *et al.* unpublished results). The characterization of these mutant proteins is in progress.

The advantages of this protocol are: (i) To obtain single and double mutants simultaneously. This procedure is useful in the case of highly conserved proteins where there are too many amino acids to be screened from structure/function point of view. (ii) It is more economical as one would need a shorter oligonucleotide (20–25 bp) compared to other methods (30–35 bp) to generate double mutants in which the two mutation sites are separated by 10–15 bp. Although the second mutation in this case is restricted to certain amino acid replacements only, the method is useful for the generation of single and double mutants. The 3' non-templated 'A' addition results only in substitution (confirmed by sequencing more than 20 different mutant clones) and will not result in a frame shift mutation as described⁸. Only two non-specific mutations were noted in more than 8 kb sequence determined for all the mutant clones.

Direct and indirect somatic embryogenesis in teak (*Tectona grandis* L.)

Rijuta Kushalkar and Madhuri Sharon

Tissue Culture Laboratory, C. C. Shroff Research Institute, Excel Estate, S. V. Road, Goregaon (W), Mumbai 400 062, India

Apical and axillary buds from three-year-old teak (*Tectona grandis* L.) were used to initiate the cultures. Callus from apical buds of teak formed globular and heart-shaped somatic embryos on Murashige and Skoog medium supplemented with 6-benzylaminopurine (BAP) (0.1 mg/l) + 1-naphthalene acetic acid (NAA) (0.01 mg/l) and 3% sucrose. However, callus initiated from axillary buds was unable to form somatic embryos on semisolid Murashige and Skoog medium with different combinations of growth regulators. On the other hand, somatic embryos were readily formed from the same callus when transferred to half strength liquid medium containing BAP (0.1 mg/l) + NAA (0.1 mg/l). Somatic embryos were directly formed from axillary buds of teak inoculated in test tubes having filter paper bridges with half strength liquid medium containing BAP (1.0 mg/l) + 2iP (1.5 mg/l).

TEAK (*Tectona grandis* L.) is an important tree known for its high value timber. However, it is slow growing besides the low percentage of seed germination. Tissue culture is a faster method of propagation. The regeneration of teak plantlets by multiple shooting of nodal segments and shoot tips^{1,2} and by organogenesis via callus culture of young and mature leaves³ has already been reported. The present report is on somatic embryogenesis in teak which has not been reported so far.

Apical and axillary buds of three-year-old plants were inoculated on semisolid Murashige and Skoog⁴ (MS) medium (pH 5.7 ± 0.1) and incubated 25 ± 2°C in dark for 72 h and then in 16/8 h photoperiod having 1200 lux light intensity. Callus initiated on MS + 6-benzyl-

aminopurine (BAP) (2 mg/l) after 7 days. Initially callus was hard, compact, white and then slowly turned green. Callus was transferred to MS medium supplemented with various permutations and combinations of BAP, 6-furfuryladenine (KIN), N_6 -(2-isopentyl) adenine (2iP), 1-naphthaleneacetic acid (NAA) in the range of 0.01–2.0 mg/l to induce differentiation.

From callus of apical bud, globular somatic embryos were formed on full strength semisolid MS medium (pH 5.7) supplemented with BAP (0.1 mg/l) + NAA

(0.01 mg/l). They further differentiated into heart-shaped embryos on the same medium (Figure 1 *a,b*). Secondary embryogenesis was also observed (Figure 1 *c*).

From axillary buds both direct and indirect somatic embryogenesis was observed. Since somatic embryogenesis did not occur on full strength semisolid MS medium, the cultures were transferred to liquid, half strength MS medium (pH 5.7). When callus was placed in liquid MS medium supplemented with BAP (0.5 mg/l) + NAA (0.1 mg/l), somatic embryos developed

Figure 1 *a–c*. Apical bud cultures of *Tectona grandis* on full strength MS medium. *a*, Indirect somatic embryogenesis; *b*, Globular and heart-shaped embryos; *c*, Formation of secondary embryos.

RESEARCH COMMUNICATIONS

from periphery (Figure 2 *b*). Globular and heart-shaped embryos were observed under the microscope after 4–6 weeks (Figure 2 *c,d*).

Somatic embryos were directly formed from approximately 2% of the axillary buds when placed on filter paper bridges in test tubes containing liquid, half strength MS medium supplemented with BAP (1.0 mg/l) + 2iP (1.5 mg/l) (Figure 2 *a*, Table 1).

Direct and indirect somatic embryogenesis from axil-

lary buds occurred on liquid half strength MS medium. Requirement of reduced amount of nutrient (MS with half major salts) for inducing somatic embryogenesis has been reported earlier in ovule culture of *Magnifera indica* by Litz *et al.*⁵ Moreover suitability of liquid medium has also been demonstrated by Raemakers *et al.*⁶ in case of cassava for inducing somatic embryogenesis.

Indirect somatic embryogenesis from the callus derived

Table 1. Effective media for somatic embryogenesis of teak

Explant	Type of somatic embryogenesis	Medium	Remarks
Callus of apical bud	Indirect	Full strength MS + BAP (0.1 mg/l) + NAA (0.01 mg/l)	Semisolid medium in test tubes
Callus of axillary bud	Indirect	$\frac{1}{2}$ MS + BAP (0.5 mg/l) + NAA (0.1 mg/l)	Liquid medium in test tubes and Erlenmeyer flasks
Axillary bud	Direct	$\frac{1}{2}$ MS + BAP (1.0 mg/l) + 2iP (1.5 mg/l)	Liquid medium in test tubes having paper rafts

from apical buds needed full strength MS medium. Requirement of full strength MS medium was also found in case of apple⁷.

Efforts are on to further differentiate these somatic embryos into plantlets.

Onset of an arid climate at 3.5 ka in the tropics: Evidence from monsoon upwelling record

Pothuri Divakar Naidu

National Institute of Oceanography, Dona Paula, Goa 403 004, India

Studies on the variability of Southwest (SW) monsoon strength using the monsoon upwelling indices (fluxes of total planktonic foraminifera and *Globigerina bulloides*) from the western Arabian Sea reveal that the weakening phase of the SW monsoon started from 5 ka (ka = 1000 years). The intensity of monsoon returned to glacial strength at 3.5 ka, coinciding with the onset of arid climate elsewhere in the tropics. The onset of the weak phase of the monsoon and arid climate at 3.5 ka appears to be a primary reason for the decline of Indus Valley Civilization, major change in vegetation along the Western Ghats and decrease of river discharge from all major rivers during that period.

DURING the Northern Hemisphere summer, strong south-westerly monsoon winds blow across the Arabian Sea, causing offshore Ekman transport and intense seasonal upwelling along the Oman and Somalia margins and the Southwest coast of India¹⁻⁴. The upwelling

process brings cold, nutrient-rich waters from a few hundred meters depth to the surface and increases biological productivity in the euphotic zone. During the winter, the Northeast monsoon winds invoke onshore Ekman transport of surface waters, which suppresses upwelling and lowers the productivity along the continental margin of the western Indian Ocean. Thus the south-westerly and north-easterly winds produce a striking seasonal contrast in primary productivity⁵ and biogenic and lithogenic fluxes⁶ in the Arabian Sea. Distinctive plankton faunas and floras thrive in the upwelling waters and are eventually incorporated into the sediments on the sea floor, producing a geological record of upwelling. The sedimentary record in the Arabian Sea is thus linked to the strength of the SW monsoon winds and associated rainfall in southeast Asia. The biogeochemical studies on these sediments therefore provide valuable information on the variability of monsoon upwelling and rainfall in southeast Asian countries over geological time scales. Recently, we have documented the general variability of the SW monsoon for the last 19 ka and its sub-Milankovitch cyclicity^{7,8}. The primary tasks leading to this communication were (i) to find out when the weakening phase of SW monsoon was set in within the late Holocene, and (ii) whether this time coincided with rapid climate shifts elsewhere in the tropics.

RESEARCH COMMUNICATIONS

The upper 7.4 m of the Ocean Drilling Program (ODP) Hole 723A (Figure 1) was sampled at 10 cm interval, which gives an approximate time resolution of 250 years. Radio carbon dates obtained on Accelerated Mass Spectrometry (AMS) were used to establish the chronology (Table 1). High resolution upwelling indices data in conjunction with precise AMS radiocarbon chronology, permit a detailed interpretation of SW monsoon variability and climate change from the tropical Arabian Sea. The details about the AMS dates and upwelling indices are discussed elsewhere⁷.

Several planktonic foraminiferal indices of upwelling were identified in the Arabian Sea⁹⁻¹¹. Fluxes of total planktonic foraminifera and *Globigerina bulloides* were used to measure the upwelling intensity in the western Arabian Sea and in turn the SW monsoon strength in south Asia.

It has been well established that the SW monsoon was weaker during glacial periods and stronger during interglacials¹². Intensification of the SW monsoon started at 12 ka, i.e. after a weak phase during the last glacial period¹³. Within the Holocene, greater values of upwelling indices have been noted between 10 and 6 ka, reflecting

a strong SW monsoon (Figure 2). The values of upwelling indices decrease abruptly at 5 ka, indicating a weakening of the SW monsoon. The lowest upwelling indices in the Holocene occurs between 3.5 and 1.2 ka (Figure 2), suggesting that upwelling and the SW monsoon intensity decreased during this period. At 3.5 ka the upwelling indices exhibit the same values as that at 12 ka, when the monsoon started its intensification after the last glacial period, and from 3.5 ka the upwelling indices decline further. Other evidences such as water levels in Ethiopian lakes¹⁴, palaeohydrological data from western Tibet¹⁵, benthic foraminifera record from eastern Arabian Sea¹⁶, pollen records from Northwest India¹⁷ and $\delta^{13}\text{C}$ values of peat deposits¹⁸ also suggest a weaker SW monsoon during this time. A similar pattern of dry conditions during the late Holocene is also reported from Africa and the regions around Caribbean.

Independent evidences such as pollen studies from the eastern Arabian Sea¹⁹, and down core variations of calcium carbonate in the western Arabian Sea²⁰ and $\delta^{18}\text{O}$ data from Tibet lakes¹⁵ also document the arid climate during this time. This observation is further corroborated by an abrupt change in solar radiation, precipitation,

1H	2	160	5,865	± 65
1H	3	290	9,100	± 90
1H	4	520	15,920	± 125
1H	5	740	19,130	± 275

Figure 2. Fluctuations in fluxes of total planktonic foraminiferal shells (>150 μ m fraction) and *Globigerina bulloides*. Ages were based on five AMS ¹⁴C dates at levels marked by dotted arrows. Thick arrows mark the start of monsoon intensification after glaciation (at 12 ka) and the weakening phase of monsoon during late Holocene (at 3.5 ka).

temperature and southwesterly winds at about 3.5 ka in the Arabian Sea²¹. The recent (2–4 ka) aeolian activity in the Thar Desert²² also corresponds with the onset of arid climate at 3.5 ka. Dry episodes including the current drought in the Sahel have been correlated with warming of the surface ocean in the southern hemisphere and the north Indian Ocean, and cooling of the North Atlantic and the North Pacific. The declining strength of the SW monsoon since 3.5 ka can therefore be interpreted as a result of the onset of arid climate in general throughout the tropics and in particular in the Asian tropics.

The onset of arid climate and decline of the SW monsoon at 3.5 ka was resulted in a change in the vegetation along the Western Ghats¹⁹. *Casuarina*, *callitris* shrubs and ferns declined during this period in South Australia²³. The Godavari, Bhima and Krishna rivers originate in the elevated region of the Western Ghats, and their discharge depends on the precipitation driven by the SW monsoon winds. These rivers discharge and lake levels in India, Africa, Australia and China also

dropped during that time. It was previously pointed out that neotectonism was responsible for the drying of the Sarasvati River²⁴. This event could, however, also be attributed to drastic climatic changes at 3.5 ka. It is well established that the down fall of Chalcolithic Cultures (about one million BC) is ascribed to severe droughts in western and central India, similarly the decline of the Indus Valley Civilization around 3.5 ka could be due to the onset of arid climate at 3.5 ka.

An obvious, but provocative question is whether the onset of arid climate at 3.5 ka is traceable in other tropical regions of the world. Evidences such as ¹⁸O/¹⁶O ratios in ostracod shells from Caribbean lakes²⁵ and pollen analysis from south Australia lake²³ have also documented the onset of an arid phase at 3.5 ka. Thus the onset of arid climate at 3.5 ka appears to be a global event, prevailing throughout the late Holocene.

Coherent occurrence of an arid climate at 3.5 ka in the northern hemisphere (present study) and southern hemisphere²⁵, and synchronous dropping and raising of water levels in Australia and China²⁶ indicate that late Holocene climate in the tropics of both hemispheres were in phase.

Two theories, viz. Milankovitch orbital theory²⁷ and deep water formation changes²⁸ have been put forward to explain the causes of glaciation and deglaciation in the Quaternary period. The Milankovitch orbital theory explains the general envelope of past glacial climatic changes, but does not explain either the timing or the amplitude of short-term changes noticed in the present study and in ice core records²⁸. On the other hand, deep water formation changes provide a more satisfactory hypothesis for explaining the ultra fast and abrupt climatic shifts in the ice cores²⁹, and marine sediment records³⁰.

It has been pointed out that thermohaline circulation changes have an influence on the rainfall in the tropics³¹. Deep water formations in the North Atlantic have a profound influence in causing the abrupt climatic shifts at high latitudes³² and probably in low latitudes too. Therefore, I suggest the missing link between the thermohaline circulation and/or deep water formations at high latitudes and monsoon intensity may be initiated to understand the onset of arid climate in the tropics and decrease of monsoon strength.

To conclude, high resolution data on upwelling indices, in conjunction with precise AMS radiocarbon chronology, permit a detailed interpretation of SW monsoon variability and climate change in the tropical Arabian Sea. The decreasing upwelling indices since 5 ka reflect a recent weakening of the SW monsoon, with the weakest phase taking place at 3.5 ka, which coincided with the onset of arid climate in other parts of tropics. The onset of arid climate during that time appears to be the main cause of declining vegetation and river discharge in the Indian subcontinent during that period. The drastic cli-

mate shift at 3.5 ka might be one of the reasons for the decline of Indus Valley Civilization.

Precambrian–Cambrian boundary microbiota from the Chert Phosphorite Member of Tal Formation in the Korgai Syncline, Lesser Himalaya, India

Meera Tiwari

Wadia Institute of Himalayan Geology, Dehradun 248 001, India

Abundant and well preserved organic walled microfossils are recorded from the Chert–Phosphorite Member of the Tal Formation, in the Korgai Syncline, Lesser Himalaya. Two principal categories of microfossils including spheromorph acritarch and small acanthomorph acritarchs are present in the assemblage. Interesting among these two categories are *Leiospheridea* sp., *Micrhystridium regulare*, *M. sp. A*, *M. sp. B*, *M. sp. C*, *M. sp. D* and *Veryhachium* sp. The appearance of large *Micrhystridium* population together with small shelly fauna has been used as a criterion to demarcate the Precambrian–Cambrian boundary in China¹ where these microfossils have been discovered from the black chert in the phosphatic rocks of the lowest Kuanchuanpu Member in Ningqiang of southern Shaanxi.

The Korgai syncline is one of the five major synclines of the Krol belt where the Blaini–Krol–Tal sequence is well exposed. It is located 15 km southeast of Nigalidhar syncline and comprises an area of about 23.50 sq km. Prior to this communication no microbiota was reported from this syncline. The material for this study was collected from a trench located in the NE of Sataun (Figure 1) approximately 4 km from Bargaun on the mule track from Bargaun to Banana village (30° 35' 16" : 77° 40' 44"). Here, the Lower Tal Formation

Figure 1a, b. a, Geological map of the area (after Auden, 1934) showing the fossil locality. A = Fossil locality, B = Chandpur and Nagthar formations, C = Blaini Formation, D = Krol Formation, E = Lower Tal Formation, F = Upper Tal Formation; b, Litholog showing sample interval. a = dolomitic limestone, b = cherty phosphorite, c = sandy unit.

consists of thin-bedded cherty phosphorite with intercalated sandy units. Dolomitic limestone of the Krol Formation underlies the cherty shale. The present microfossils are preserved in the phosphatic chert. These fossiliferous cherts are aphanitic and non-laminated. The chert is composed predominantly of cryptocrystalline and microcrystalline quartz with lesser amounts of fibrous calcedony, amorphous organic matter, well preserved microfossils (acritarchs) and minor opaque fine-grained pyrite crystals and orange hematite framboids. All specimens discussed here are observed in petrographic thin sections.

In Lesser Himalaya, spheromorph acritarchs have previously been recorded from the Chert Phosphorite Member of the Tal Formation². Tiwari and Knoll³ described acanthomorphic acritarchs from the stratigraphically lower Infrakrol Formation. However, this is the first report of acanthomorphic acritarchs from the Tal

Formation. The present microbiota is characterized by a unique assemblage. The forms are assigned to *Leiospheridea* sp., *Micrhystridium regulare*, *M. sp. A*, *M. sp. B*, *M. sp. C*, *M. sp. D* and *Veryhachium* sp. (Figure 2) associated with rare filamentous forms. *Micrhystridium* has been known in the lowest Cambrian non-trilobite bearing Meishucun Formation⁴⁻⁸. However, *Veryhachium* sp., which is larger in size in comparison to those species reported from Paleozoic, has not been previously reported from the Precambrian-Cambrian boundary level or the underlying sediments, with the exception of some rare specimens from Proterozoic rocks^{9,10}. This genus is commonly found in the lower Paleozoic which generally is smaller in size.

This communication mainly deals with the discovery of abundant *Micrhystridium* and *Veryhachium* from the Chert Phosphorite Member of the Tal Formation. The occurrence of *Micrhystridium* is very rich in the samples.

Figure 2 a-l. a, b, *Micrhystridium* sp. A in two different foci, c, d, *M. regulare* in different foci; e, h, *M. sp. B*; f, *M. sp. C*; g, i, j, *M. sp. D*; k, *Leiospheridia* sp.; l, *Veryhachium* sp. Scale bar for Figure h is 10 μ m and for Figure l is 50 μ m. (Scale bar for a-j is shown in l and for k is shown in l).

It is closely comparable to the *M. regulare* reported from southern Shaanxi and also resembles with *Micrhystridium* sp. of Lo described from the Lower Yudoma suite of eastern Siberia¹¹. The presence of *Veryhachium* is unique in the assemblage. Small shelly fossils are not reported from this locality so far, but the acritarchs-yielding level in the Korgai syncline has also yielded SSFs in Mussoorie and Garhwal synclines¹²⁻¹⁵ and also in Nigalidhar Syncline¹⁶. This study shows a close similarity in the microfossil yield of the basal Meishucunian levels in the Lesser Himalaya and the Chinese section. Simple *Micrhystridium* population also occur in the lower Yudoma Formation in Siberia¹¹. Besides, the acritarchs of basal Tal Formation differ greatly from those of Infrakrol Formation³, where large acanthomorphic acritarchs (> 100 µm in diameter) predominate. The presence of smaller acanthomorphic acritarchs in the basal Tal (Cambrian) in comparison to the older Infrakrol Formation (Precambrian) strengthens the concept of decrease in the size of acanthomorphic acritarchs from the Precambrian to the Cambrian¹⁷.

Potential threat to reservoir fishery by fungi in Kumaun Himalaya, India

G. S. Bisht*, Deepa Bisht, Chandra Joshi and R. D. Khulbe

Botany Department, Kumaun University, Nainital 263 002, India

*Present address: Vivekananda Parvatiya Krishi Anusandhan Sansthan, Almora 263 601, India

Zoosporic fungi are among the most destructive fish pathogens. Eighteen species belonging to *Achlya*, *Aphanomyces*, *Dictyuchus*, *Saprolegnia* and *Pythium* were isolated from Nanak Sagar, which has witnessed mass mortality of fish fauna during 1991-94. Of these, 8 species were also detected from diseased and moribund fish. Species of the parasites and the hosts demonstrated differential pathogenicity and immunity respectively. *Achlya flagellata* and *Saprolegnia parasitica* appeared virulent, while scaly-fish were more vulnerable to fungal infection than the non-scaly fish. The occurrence of fungal species, zoospore density and severity of mycoses was primarily governed by temperature. A water temperature between 22 and 25°C during spring stimulated fungal activity whereas, at above 28°C it retarded the disease process. All the species, except *A. inflata* and *P. vexans* have been reported virulent fish pathogens elsewhere; this is cause of great concern. By virtue of a wide distribution and potentiality to parasitize eggs, fingerlings and adult fish, these fungi along with anthropogenic pressure are most likely to pose threat to reservoir fishery. Thus, research on integrated management of fish mycoses is warranted.

RESERVOIRS, the artificial ecosystems characterized by the existence of both lentic and lotic components, constitute the prime inland fisheries resource in South and South-east Asia. A major increase in inland fish yield in India is expected from reservoirs because of construction of new dams and the improvement in reservoir fisheries management¹. Beside wide diversity of fish, reservoirs also harbour diverse microorganisms including fungal species which occur as opportunistic pathogens of aquatic organisms, specially of fish^{2,3}. Water molds, the zoosporic fungi, are a constant and ubiquitous component of aquatic environments and a continual challenge to fish⁴⁻⁶. The ability of these fungi, particularly of those belonging to *Achlya*, *Aphanomyces* and *Saprolegnia* to parasitize eggs, fry, fingerlings and adult fish has been well documented⁵⁻¹⁹. As a general rule, infection starts when the host gets injured either mechanically^{9,10} or as a result of infection other than fungal, which often results in epidemic, causing 100% mortality of the infected hosts^{10,13,18}. However, the clinical and pathological investigations have revealed that several members of Saprolegniales often act as primary pathogens^{5,6,11-19}, thereby play a vital role in minimizing the total output

of fish industry either way. In a preliminary study, prevalence of mycoses was observed at a reservoir in Nainital district¹⁹. However, in spite of their great economic value, the zoosporic fungi of the reservoirs are least explored.

Kumaun region abounds in lakes and reservoirs. Behgul, Nanak Sagar, Tumaria and Dhaur harbour a high diversity of fish fauna and are well recognized fish production centres of Government of UP, India²⁰. During a recent exploration (1991–94) of Kumaun Himalaya for water molds, fungal infection was noticed on several species of fish both in lakes¹⁷ and reservoirs^{18,19}. A high prevalence of mycoses on fish species, was, however, observed in Behgul and Nanak Sagar reservoirs¹⁹. Considering the seriousness of the situation, and importance of reservoirs; occurrence, phenology and pathogenic behaviour of water molds to fish and the influence of physicochemical properties of water on the occurrence and infection of zoosporic fungi were investigated at Nanak Sagar.

A large number of individuals of each major contributing fish species were randomly inspected at the fish catching site of Nanak Sagar (29°55'N and 79°40'E; 200 m amsl) spread over 4662 ha in UP hills. Minute signs of disease were observed using a powerful hand lens. Water samples were also collected at a month interval for two years. Certain important characteristics of the water were also estimated following the standard methods of the American Public Health Association²¹.

Symptomatic fry and adult fish were collected in sterile polythene bags, placed in ice in aseptic glass pots and immediately brought to the laboratory. Portions of infected tissue were washed individually with several changes of sterile tap water, and treated with 0.01%

potassium tellurite solution to avoid bacterial contamination. The infected tissues were then aseptically transferred to sterilized petri plates and baited with sterilized hemp seed (*Cannabis sativa* L.) halves. To isolate zoosporic fungi from water, 20 ml of each sample at different dilutions was poured into a sterilized petri plate and baited with different baits⁶. The plates were incubated at 15°C and fungi that colonized were purified, cultured and identified following various monographs^{6,21–22}.

In all, 18 species of zoosporic fungi belonging to 5 genera were isolated (Table 1). *Achlya* and *Saprolegnia* constituted a major proportion, were represented by 8 and 4 species, respectively. Zoospore density of these taxa was recorded in the range of $5\text{--}25 \times 10^3 \text{ L}^{-1}$, which was higher than the species of *Aphanomyces*, *Dictyuchus* and *Pythium* ($2.5\text{--}5 \times 10^3 \text{ L}^{-1}$). These fungi exhibited seasonality of their occurrence, which was closely related with water temperature. Maximum number of species as also high zoospore density of individual species were recorded during February and March (Spring) while a minimum in May and June (Summer). A few species, viz. *Aphanomyces laevis*, *Dictyuchus sterile*, *Saprolegnia ferax*, and sterile isolates of *Achlya* and *Pythium* could resist the summer temperature ($>32^\circ\text{C}$). Majority of these species have shown adaptability to different habitats in the region²⁴.

Of the fungi recovered from water, eight species were also isolated from individuals of 5 fish species exhibiting mycotic symptoms (Table 1). Infection is characterized by depigmentation of body colour, external haemorrhage, descaling, eroded tails and dorsal fins which led to surface swimming and sluggishness and ultimately to death. Colonization of whitish wooly tuft on to infected

Table 1. Occurrence, seasonality and parasitic association of water molds to fish in Nanak Sagar, and elsewhere

Fungal species	Seasonal periodicity	Associated with fish mycoses	
		Nanak Sagar (Reference)	Elsewhere (Reference)
<i>Achlya americana</i>	Spring, rainy		6, 15, 10, 13
<i>A. debaryana</i>	Spring, rainy	18, 19

portion is often visible. *Saprolegnia parasitica* was detected from *Mastacembelus armatus*, *Mystus vitatus*, *Tor putitora* and *T. tor*; *S. ferax* from *M. armatus*, *Nandus nandus* and *T. tor*; *A. debaryana* from *M. armatus*, *T. putitora* and *T. tor*; *A. flagellata* was found to be associated with *T. pitutora* and *T. tor*; while *A. klebsiana*, *Pythium* sp. infected *N. nandus* and *T. tor*, respectively. These pathogens caused identical signs in different hosts. However, the disease intensity varied with the host and the pathogen.

The infection began during the first week of February and by the middle of the month, substantial proportion of the fish population got infected. By that time, incidence of mycoses on *M. armatus*, *M. vitatus*, *N. nandus*, *T. pitutora* and *T. tor* was recorded 36.6, 32.0, 29.8, 28.4, 33.6 per cent, respectively. The infection spread rapidly and peaked by the middle of March, decreased thereafter and was minimum in June when the water temperature was high (32°C).

Water temperature between 22 and 25°C, coupled with a high pH (8.6–8.7) and moderate DO (8.5–9.5 mg/l) favoured zoosporogenesis in fungal forms and their subsequent infection on fish. A maximum disease incidence in March coincided with a water temperature of 23°C, a pH of 8.6 and a DO of 9.5 mg/l. Temperature more than 28°C of May through June, suppressed the growth and pathogenicity of the fungal species, resulting in minimum disease incidence of fish¹⁹. Retardation of the pathogenic potentiality of the species at higher water temperature may be due to induction of gammae and oospore formation which cannot infect fish and require a certain period of dormancy^{18,19}. Since July to September is breeding season for the fish, the reservoir is closed for fishing from July to November. Because of this regulation, no data on infection could be available for this period. However, fish eggs which are highly susceptible to fungal infection^{5,6,10,13}, obviously were destroyed during this period. As water molds were abundant during September onwards, their infection on fingerlings and adult fishes is likely. This may be one of the reasons for dwindling fish yield of the reservoir.

Several species of water molds have previously been reported as causal agents of diseases and death in fishes^{4–19}. *A. flagellata* which has long been known as fish pathogen⁷, has recently been reported to be associated with *T. tor* and *Puntius ticto* in temperate lakes¹⁷. Similarly *S. parasitica* parasitized four fish species in Nanak Sagar¹⁹, has also shown potentiality to parasitize several species of fish^{5,8,10,11,16,17}. *A. debaryana* was responsible for epizootic infection on a cat fish¹⁸. Similarly, *A. klebsiana* on *P. conchonious*, *A. laevis* and *S. diclina* on *P. ticto* and *S. ferax* on *Tor tor*⁶ have been reported to be pathogenic.

Moreover, fungal species which were isolated from reservoir but not found associated with fish during the

present investigations, have been reported virulent pathogens of eggs, fry, fingerlings and adults of several fish species elsewhere^{5,6,11}. *A. americana* has been reported as parasite of freshwater fish *Lepomis macrochirus*¹⁰ and several tropical and temperate fish¹⁶. Likewise, *A. orion* has shown its pathogenicity to twelve species of freshwater fish, four belonging to *Puntius*, *Chanda*, *ranga*, *Channa marulion*, *C. punctatus*, *Notopterus notopterus*, *Labeo rohita*, *Colisia lalia* and *Anabas testudineus*^{5,12}. *A. laevis*, *D. sterile* and *P. undulatus*^{6,14} have also been reported pathogenic to cold water fish. Fish eggs are also attacked by these fungi, infected eggs generally do not hatch and are destroyed, thus causing a colossal loss to the fish industry^{5,6,10,13}. A heavily sporulating sterile isolate of *Aphanomyces* has been reported to cause 100% mortality in eggs of *Channa gachua*, while *A. prolifera*, *A. orion* and *Aphanomyces laevis* caused more than 90% egg mortality¹³.

Foregoing discussion reveals that water molds flourishing in Nanak Sagar have wide distribution, and possess great potentiality to parasitize fish⁶. Most of these have a wide host range and any of them can cause substantial loss under congenial conditions. Moreover, a rich mycoflora of parent rivers and within their catchments contribute to the mycoflora of reservoir(s) in terai region. Once established in the reservoir by virtue of parasitism in fish or saprophytic existence, these fungi produce gammae, chlamydospores and oospores that persist for many years and are virtually impossible to eliminate, thus, may pose threat to fish under congenial conditions. Further, the more or less similar mycoflora, Ichthyofauna and physio-chemical properties of water of different reservoirs in terai region has made reservoir fish vulnerable to fungal infection. Under intensive system, such as hatcheries and fish farms mycoses has always been a problem and unless adequate hygienic and husbandry methods are employed, grave losses can result. In some habitats these organisms have been responsible for extinction of some fish species. Himalayan Mahseer, *T. pitutora*, *T. tor* and some other valuable and rare species of Himalayan fish which are disappearing, are prone to fungal infection¹⁹, which beside anthropogenic pressure may contribute to their fast depletion. Unistam²⁵ also reported that water molds were responsible for the extinction of fish species in certain habitats of Australia. Thus, there is an urgent need to undertake prophylactic measures to protect the fingerlings before introducing into the reservoirs. These should be treated with Melachite green, tetracycline, formaline, boric acid and other suggested chemicals in recommended concentrations^{26–28}.

In addition, several species of *Olpidiopsis* are known to parasitize on Saprolegniales. *O. achlyae* on *Achlya* sp., *O. fusiformis* on *A. prolifera*, *O. luxurians* on *A. laevis*, *O. saprolegniae* var. *laevis* on *Saprolegnia* sp.

and *O. pythii* on *Pythium* sp. have been reported from Kumaun²⁴. Thus, hold potential to suppress population of fish pathogens; and intensive research on biological control of fish mycoses is warranted.

TECHNOLOGY DEVELOPMENT BOARD

**Department of Science & Technology
Government of India
New Delhi 110 016**

FINANCIAL SUPPORT FOR TECHNOLOGY DEVELOPMENT

Proposals are invited from:

- (i) Industry
- (ii) Research and Development Laboratories, and
- (iii) Academic Institutions and other agencies

for providing assistance to technology development projects for commercialization purposes.

A Technology Development Board, under Department of Science & Technology, Government of India, has recently been constituted for –

- (i) accelerating development and applications of indigenous technology; or
- (ii) adapting imported technology for wider domestic applications.

Industrial concerns and other agencies engaged in attempting commercial application of indigenous technology or adapting imported technology for wider domestic application, can apply for the financial assistance to supplement their efforts. The projects could be undertaken solely by industry or jointly with national laboratories, IITs, IISc, and universities or scientific and industrial research organizations, etc. The financial assistance by the Board may be in the form of:

- Grants
- Loan
- Equity

Interested parties may send their proposals furnishing full details of the proposed project as required in the *prescribed proforma* including title of the project, objectives, project cost, financial support sought, duration, names and role of other participating agencies including R&D laboratories, if any, action plan including milestones and phasing of expenditure, market demand, expected commercial output and techno-economic benefits along with annual reports and audited statement of accounts of the industrial organization for the past three years. For further details, please contact:

How hot will India be in 2040?

Few topics have generated more heat than the study of global warming. The dispute is not so much about whether it is taking place at all (there is more than adequate evidence to convince almost everyone), but about (a) the relative importance of the contributing factors, and (b) the reliability of the predicted magnitudes of the warming. Opinions really span a wide range. At one extreme, one finds a contemptuous dismissal of the whole global warming research as a gigantic fraud (a dismissal not untinged with envy – few subjects have attracted bigger grants than the study of global climatic change). At the other, there are true believers who claim that unless immediate and drastic steps are taken, vast deserts will be our only legacy to our great grandchildren. In any event, the matters are being taken with enough seriousness at the international level, and the control over discussions is slowly but surely being taken over by administrators, diplomats and politicians from scientists (or is it from scientist-administrators, scientist-diplomats and scientist-politicians?).

The scientists, nevertheless, continue to be busy with the task of refining their models by including more and more factors likely to influence this vastly complex system. Parallely, they have also begun examining the patterns of warming on smaller (and thus perhaps more relevant) scales, and also the finer details of the patterns. One such study, by M. Lal, G. Srinivasan and U. Cubasch (page 746), deals with the situation concerning India – something which would be of more interest to most readers of *Current Science*.

Lal *et al.* have based their investigations on the data generated by

the numerical experiments performed using the European Community Hamburg atmospheric model, coupled to a Large Scale Geostrophic model, which include all such factors as air-sea fluxes of momentum, short and long wave radiation and fresh water. They have used three scenarios – first a control, second one with enhanced CO₂ levels but without sulphate aerosols, and the third which also included sulphate aerosols. Though increased levels of CO₂ cause warming, higher levels of sulphate aerosols are known to cause cooling, thereby moderating the extents to which the temperatures can rise. By comparing the observed rates of warming over the Indian region for the period 1880 to 1989 with those predicted by the models for the three scenarios, the authors demonstrate that only by inclusion of sulphate aerosols can one obtain a satisfactory fit between the data and the model. The observed warming trend of 0.6 degrees per 100 years for the maximum temperature is very well reproduced by the third scenario, which can now be used for predicting the future with a higher degree of confidence.

However, knowing the extent of increase averaged over the entire Indian region will be about as useful as knowing the 'average' depth of a river (for a non-swimmer who wants to cross it). One of the major effects of warming is expected to be on crop productivity, and that varies of course from crop to crop, and therefore from region to region and season to season. With this perspective in mind, Lal *et al.* have investigated the finer details of the pattern of warming. They have primarily looked at the maximum and minimum temperatures, at the annual time scale as well as separately for winter, monsoon, premonsoon and post-monsoon. A curious feature

predicted by them is the reduction in the diurnal temperature range. Looking at the spatial patterns, the model predicts no significant increase for the north-east India by 2040, but suggests a rise of 1.5° along the western margin. Prospects for the other regions can also be seen.

Plague: The aftermath

The plague outbreaks in Maharashtra and Gujarat between August and October 1994, were a sharp reminder of 'India's vulnerability to emerging and re-emerging infectious disease'. The plague episode underscored the inability of the government to react swiftly to unexpected crises and to counter mounting public panic in a calm and effective manner. India's image worldwide was badly affected by the unseemly image of foreign air carriers avoiding a country suddenly host to a medieval scourge. While the government and the media contributed substantially to the autumn madness of 1994, Indian science did not come out covered with glory. The uncertain initial response to the plague outbreak was the result of a continued complacency of the medical establishment to the ever-present threat of communicable disease. For a brief period, the deficiencies of our systems to monitor and unambiguously identify the disease were starkly highlighted. For a while there were only questions. Was it plague after all? What triggered the sudden outbreaks? Why was it bubonic plague in Beed, Maharashtra and pneumonic plague in Surat, Gujarat? Why was the spread of the disease so unlike text-book descrip-

tions of plague epidemics of yore? Did the large-scale consumption of antibiotics (tetracycline) influence the pattern of the epidemic?

Now, two years after the event, *Current Science* carries in a special section (pages 781-808) several technical papers which are the outcome of the work of the Technical Advisory Committee on Plague, constituted by the Government of India. The articles make many key conclusions; the most important being the definitive statement that the organisms isolated from tissue samples of patients in Surat and from rodents and fleas in Surat and Beed are indeed *Yersinia pestis*, the causative agent of plague. Biochemical analysis using PCR methods and ribotyping provide a firm basis for the identification. Some questions still remain. Why was there an extra protein band in the initially observed Surat strains? Was there a direct connection between the bubonic plague of Beed and the pneumonic plague of Surat? The articles attempt to examine the linkages between the ecology of the affected areas and the transmission of the infection. The relationships between the plague episodes and the September 1993 earthquake in Maharashtra and the September 1994 floods in Surat remain unclear. If there is indeed a connection, it is surprising that this disease does not break out more often in a country frequently visited by natural calamities.

The plague committee's report leaves much unsaid. The difficulties

of collection of samples, the problems of inter-laboratory interactions and the valuable time that was lost at the height of the outbreak find little or no mention. By the time the committee was formed, the outbreaks had subsided. The work on identification of the causative organism, therefore, had to depend on samples already collected and stored, with contamination being a major issue (page 782). In the early days, reports of inadequate collaboration and lack of cooperation between investigating laboratories were written about in the popular press. To its credit, the plague committee successfully coordinated a major exercise in scientific investigation spread out over a wide network of laboratories.

What lessons have been learnt? The government has responded by establishing a National Apical Advisory Committee (NAAC) for National Disease Surveillance and Response System. Clearly more than plague looms on the horizon. Malaria, tuberculosis and AIDS are everpresent threats and indeed in 'lay English usage', plague is a term with a much larger definition (page 807). Will the permanent existence of a committee help to combat sudden outbreaks of disease? The dengue fever episode of October 1996 suggests that the lessons of the plague have not really been learnt well. Our public health systems, overburdened far beyond their capacity, are extraordinarily fragile. Our fledgeling biomedical research enterprise is still to come

to a stage where quick, state-of-the-art responses are possible. With limited scientific expertise spread thinly across the country, coordinated efforts have to overcome formidable barriers. Chronic underfunding and a lack of appreciation for the importance of scientific research in most medical institutions have completely damaged the base of medical research in India.

The premier agency, the Indian Council of Medical Research runs a network of laboratories, which surprisingly do not seem to house much of the expertise needed to tackle the problems thrown up by epidemics like the plague.

The plague articles in this issue should stimulate rethinking on our approach to disaster management, particularly in the area of public health. Should we not have contingency plans and pre-arranged networking of laboratories? Should not the Health Ministry be the domain of health professionals and biomedical scientists? Are institutions like the National Institute of Communicable Diseases and ICMR fully equipped for future challenges? We would do well to heed the warning: 'Because of the capacity of microbes to adapt to new circumstances, there will probably be a continuing battle for many years, a subterranean war in which complacency and lack of determination can result in pain and death'. (D. E. Koshland, *Science*, 1992, 257, 1021).

CORRESPONDENCE

Role of DST

Farooqui *et al.* (*Curr. Sci.*, 1996, 70, 482–483) state at great length that the DST is efficiently encouraging young scientists; within 3–4 months most of the applications are adjudicated. As a contrast, let me record the experience of an old scientist. After working on cephalopods at the Eastern coast for many months at my personal expense and obtaining some results, I submitted an application for a very modest grant for a project to be executed in collaboration with a Central Government organization. In spite of reminders I heard

nothing from DST. After about a year I requested a friend to enquire at Delhi. Several times he did so and the answer was, – ‘Oh, well, we remember that a reply has been despatched but that a copy of it is not available at the moment.’ After another year or so, I despatched a copy of the project to DST explaining everything and requesting them to initiate the project as a new one. This time I received a very prompt reply explaining that (about two years ago) a negative decision had been taken. No referee’s report was included. By that

time the results obtained were in press in the form of a paper and during these two and a half years I have been paying my expenses for food and journey from my pension.

I then applied to the West Bengal DST and a positive decision was communicated to me within two months.

Long-range forecasts of the total monsoon rainfall of India

The total rainfall over India during the south-west monsoon period, June to September, averaged over a period of more than a hundred years is 85 cm. It is usually called the *normal*. For the last 9 successive years, India had the good fortune of having a normal monsoon, which technically means within plus or minus 10% of 85 cm of rainfall. It is creditable that the India Meteorological Department (IMD) successfully forecasted normal monsoon for all these years. For this purpose, IMD had developed a long-range forecast model called Multiple Power Regression Model, involving 16 global antecedent parameters – 6 Indian and 10 outside India. They are oceanographic, and meteorological – surface and upper air.

Since 1890, on demand from the Government of India, IMD has been supplying long-range forecasts of the total monsoon rainfall over India, with varying degrees of success. Since 1920s they were based on multiple regression models originally developed by Sir Gilbert Walker. Their success has been less than that of the present model.

It may be mentioned that India is ‘top’ in this field.

These long-range monsoon forecasts are for the use of the Ministry of Finance and the Ministry of Agriculture of the Government of India. When a bad monsoon is envisaged, the Finance Ministry has to make financial allotments for meeting scarcity cum famine conditions. Industrial production will be adversely affected due to reduction in hydel power generation and fall in the availability of agricultural raw products. The Ministry of Agriculture has to make arrangements for the dispersal of buffer stocks of food grains to the provinces and districts, for the supply of quick harvesting seeds for a second sowing, etc. An analysis of the past available data shows that a poor monsoon of the kind we had in 1972 or 1986 would result in a loss of around Rs 20,000 crores to the nation (at the present prices). The Finance Ministry therefore needs a long-range forecast of the following monsoon rainfall a month or two ahead of the onset of the monsoon.

In the early days, these long-range monsoon forecasts were not issued to

the public, lest a forecast of poor monsoon should encourage hoarding of food grains by dealers. Later the government decided that these forecasts be published, so that there may be no hoarding at least when a normal or a good monsoon is anticipated.

Of late, a few non-meteorological scientists have severely criticized the IMD saying that such forecasts are of no use for the farmers. Apparently, they do not realize that these forecasts are not meant for the farmers. The IMD gives short-range forecasts for farmers in the *Farmer’s Weather Bulletin*. The meteorological community inside and outside IMD is trying hard to evolve models for providing long-range rainfall forecasts for smaller areas of the size of meteorological sub-divisions and for shorter periods of one month ahead. Let us all wish them success.

Oldest emergent continental crust

Even though oldest known Archaean rocks date back to 3.96 billion years, it is not clear when the ancient crust actually emerged out of the primeval oceans that had covered the entire Earth, i.e. when the first continental crust formed and remained stable. This rarity of the early crust (Figure 1) among the continents is attributed by some to the fact that they accumulated slowly over millions of years, while some others believe that most of such crusts that rose above the sea plunged subsequently back into the mantle. However, the search for these early fragments of crust has recently resulted in the discovery of an undisturbed greenstone succession in the Pilbara Craton, Western Australia¹. This strata lying beneath the rocks of the Warawoona Group revealed typical angular unconformity, indicating that they remained stable long enough to be exposed to weathering by wind and water to produce erosion surfaces. Isotopic Pb-U dating of zircon crystals from these rocks indicated their age to

be 3467.6 ± 3.7 million years, half-billion years older than the oldest evidence of continental basement hitherto known (all the greenstone supra-continental volcanic and sedimentary succession deposited over eroded continental basements indicate ages below 3.0 billion years²). The findings have only strengthened the strongly held view that substantial volumes of continental crust existed during the first billion years of Earth's history, though most of them were recycled into the mantle³. This discovery promises to provide a much sought after material – weathered detrital remnants or palaeosols which are strongly believed to lie below the unconformity. These would be very valuable as they could provide useful data about the presence of free oxygen and carbon dioxide in early atmosphere, about the greenhouse effect, and silicate weathering. More importantly, they may provide further information about the beginnings of life on our planet, especially since the oldest fossil cells that

were found more than a decade back were from the very Warawoona Group lying above this unconformity⁴.

Earthquake precursors

Viable early warning systems for natural calamities such as cyclones and volcanic eruptions are available, but earthquakes have eluded scientific attempts of forecasting. In the recent past three independent groups have published results of their systematic studies on some of the early though (not fully established) indefinite pointers that often precede earthquakes. Two seismologists, Pierre F. Ihmlé and Thomas H. Jordan have noted¹ in 20 cases investigated by them indirect evidences of large energy releases called 'slow earthquakes' (low frequency seismic anomalies) minutes prior to the major event. Their observations are from 19 oceanic events and only one continental event from southern Sudan (Intracontinental transform fault in the East African Rift System). These are important clues mostly obtained from seismic events over the oceanic crust, but to be considered as reliable precursors for predicting earthquakes over the land, systematic monitoring of such early signals in quake-prone regions of the continents must be undertaken.

Sudden chemical changes in subsurface waters have been observed by two teams of Japanese scientists², days before the devastating 7.2 magnitude earthquake of Kobe, Japan, in January 1995. The concentrations of dissolved chloride and sulphate ions in the groundwater below

Figure 1. World map showing areas (striped) more than 2.5 billion years old.

Kobe started increasing steadily five months before the actual earthquake and peaked more than a month after the event. Similarly, concentrations of radon in groundwater increased some four-fold several months before and shot up to ten times just nine days before the January event³. Such co-seismic changes were observed by researchers of Kyoto University also during the 7-8 magnitude events that occurred in 1994. Hydrogeochemical changes of this nature have been noticed earlier in some of the Asian earthquakes also but the data have been mostly of a qualitative nature and no systematic monitoring or quantitative measurements of such precursors were attempted to be useful for early predictions.

Changes in the electromagnetic field (successfully used for prediction originally by Greek physicist Panayiotis Varostos), and emission of high frequency radiowaves have been noted in earthquake-prone areas. Monitoring of these phenomena had enabled prediction of earthquakes in southern California (January 1994) and Kobe in Japan (January 1995) (ref. 4).

Herbivorous crocodile fossil

Chinese geologists, surveying for petroleum some three decades ago, came across a 120-million-year-old skeleton with unusual features, in the lower Cretaceous of Huei Province of central China, and baffled by the uncommon features of its build, tentatively identified it as a peculiar animal. Recently, the fossil was resurrected from the shelves of Toronto Museum and re-examined¹. It has now been identified as

belonging to crocodile family and has been named *Chimaerasuchus paradoxus*. The skeleton consisting of snout, lower jaw, shoulder girdle, 15 vertebrae, forelegs, hand, pelvis and thigh bones provided a very good reconstruction of the animal – about 3 to 3.5 feet long with forward-pointing nostrils (unlike the normal carnivorous ones with up-pointed nostrils). What was, however, surprising was its multicuspid molar teeth which strongly indicated that the crocodile was herbivorous. Quite unlike the sharp conical teeth of carnivorous crocodiles, *Chimaerasuchus* had relatively flat teeth with distinct cutting edge at the back – features specialized for a fibrous plant diet, and comparable to some of the mammals and mammal-like reptiles.

Food security in 2020 and beyond – Will the developing countries be dependent on the developed world?

Suresh K. Sinha

Food and nutritional security global, regional, national and household is now the focus of concern, debate and conferences. The Food and Agriculture Organization (FAO) will be holding a conference of the Heads of Governments in November 1996 to possibly present the state of food and food security around the world. The heads of governments in their wisdom and commitment to social cause may fix a date by which every human being not only in developing countries, but in the world will have quality food and safe drinking water. The heads of governments had committed to this more than two decades ago. However, today despite enough food production in the world, about 800 million people remain hungry and most of them have a little chance to reach their genetic potential. Food in the past has been a mild weapon in the hands of those who had enough to supply through aid and trade, mostly the latter, but in future it is likely to be a powerful weapon both economically and politically. Therefore, it is time that the developing countries take a serious note of various studies and conferences to be prepared to face the most difficult challenge about to be confronted.

Three major studies or reports have appeared in 1994 and 1995. They are (i) World Agriculture: Towards 2010, An FAO Study¹, (ii) Global Food Projections to 2020 (refs 2, 3): Implications for Investment by the International Food Policy Research Institute under their 2020 Vision Programme, (iii) Full House by Lester Brown and Hal Kane of the Worldwatch Institute projecting the food demand in 2030. Some of these or their preceding studies have also been used as inputs for estimating trade in scenarios of climate change.

The future food demand would be determined by the size of population and purchasing power of the masses, which would be linked with economic growth and employment. The food security in turn would depend upon the balance between the demand and supply

and the latter depends on agriculture because, as of now, there is no such development in sight in science which would replace agriculturally produced articles of food (here agriculture includes both land and water based production systems including forests). There is a fair amount of consensus on projections of population to the year 2010 and 2020 based on UN and World Bank reports. According to these projections, the world population would increase to 8 billion by the year 2020. Of the total increase of 2291 million population in 2020 relative to 1995 population, the developing countries would add 2148 million and the developed countries would add only 143 million. Projections are projections and not predictions (Table 1). How biological system would respond to the changing environment is hard to predict. Nevertheless, we have these projections as the basis of estimating food demand. The projections suggest that five populous countries, China, India, Indonesia, Brazil and Nigeria would have half of the world population by 2020. Most of these countries and many others are improving their economic growth, which would help them improve/change their food consumption pattern. Would the consumption pattern change with increasing income as in developed countries?

Food grains, particularly cereals, are often taken for projecting food demand. This is possibly true of some societies. Therefore, there is an emphasis on projecting the demand for food grains. Also, some of the studies do have projections of animal products, vegetables, fruits, etc. though food grains are generally used as the index. Since we are

dealing with many variables: population, economic growth, climate, technology development, pricing and trade, it is difficult for anyone to make predictions, because a change in any one of the factors could influence the prediction. Therefore, models are used to project demand, supply and trade. The trade for various food commodities is a major outcome of most of the studies. The models do consider the various scenarios of population growth. However, the other inputs are not only based on insufficient data for most countries, but include guesstimates. To quote the methodology of the FAO study 'The results of this research were supplemented by guesstimates'. This is nothing new because guesstimates are liberally used for projecting the impact of climate change on many sectors of the economy. This is partly inevitable because there is a need to project the future of mankind. The fact, however, is that the estimates of demand and supply from different models differ substantially (Tables 2 and 3). For example, one study shows that the former Soviet Union Countries would be surplus in food grains, and yet they had a substantial deficit in 1990. Furthermore, the results show a deficit of 188 million tonnes of food grains by 2020 in developing countries, but the developed countries produce exactly the same surplus for enabling trade between the developing and developed countries as has been shown by the studies of International Food Policy Research Institute (IFPRI). It is projected that in 2020, China would have a deficit of 22.2 million tonnes of cereals, mostly wheat, while India would have a surplus over the demand of 2.2 million tonnes. The

Trade	0	188.2	-188.2

IFPRI study by Rosegrant has used a model where the past trend of yield, the effective producer price, etc. are important components³. A farmer in a subsistence society or in many developing countries grows a crop for his family consumption only, and very few farmers have marketable surplus. Therefore, the effective producer price based on the market price does not play a major role in production by farmers. The past trend in yield cannot always be an indicator for the future. Therefore, the trade models do not capture the realities of production system in developing countries. But according to Brown and Kane⁴ by 2030, the grain deficit in China would be 216 million tonnes and in India would be 45 million tonnes. Thus,

it is difficult to comprehend how such dramatic changes are expected when the population is expected to stabilize by this time. There is either something wrong in models or the inputs used in these models are based on insufficient information. There could as well be a bias towards trade and incapability of the developing countries for meeting their most important needs. The question which should be taken up is whether the present day food importing countries have the natural, human and technological resources to meet their requirements. In the late 50s and early 60s India was described as a nation which would be inflicted by food shortages leading to famines and social disorder. Fortunately, a combination of

Worldwatch Institute	2030	<433.0

factors in 1966 has made the country self-sufficient. The availability of new technology had a major contribution towards self-sufficiency.

While it is good to state that the developed countries would meet the demand of developing countries, but how many developed countries are today exporting food grains. Most of the export comes from four countries, among them the United States is a major exporter. Would these countries be able to meet the increasing demand for food grains? How much potential they have to produce more in view of the important considerations of sustainability, climate change, declining population on farms (reaching 2 to 3%) and increasing cost of production including the cost of energy.

Several studies in the past made an assessment of production potential of agriculture based on the climate, soil and other natural resources⁵. If these estimates are of any value, then the countries of Africa, Latin America and South Asia are presently producing much lower than their potential. Both technology and investment are the limitations as can be seen by the results of various national and international research centres. For example, the average productivity of Cassava in several countries of Africa ranges from 5 to 12 tons per ha, but experiments at the International Institute of Tropical Agriculture had shown the productivity of 42 tons ha⁻¹ of fresh and 13.0 tons ha⁻¹ of dry Cassava. These examples could be multiplied for the various crops such as rice, wheat, maize, vegetables, etc. If the developing countries have to increase their productivity and production they would have to combine the use of improved varieties with the use of fertilizers, pesticides, water management and post-harvest technology. All these are achievable objectives.

Approach to global food security: The global food security will be

Figure 1. Performance of wheat yield in India.

Figure 2. Performance of yield of nine major oilseeds in India.

determined by many factors as listed below:

1. Population growth and its distribution
2. Production of agriculture systems
3. Consumption pattern
4. Economic growth.

There is no doubt that population growth needs to be regulated in developing countries. But is it the only solution as has been advocated⁴? Obviously, the emphasis has to be on the production

of agricultural commodities as well as the consumption pattern preferred by the people. Would the replacement of Cassava and yams produced locally, by imported wheat and rice solve the problem of food security in Africa? This would mean improvement of the local systems of agriculture by introducing modern techniques, but possibly affecting trade in food grain from developed to developing countries. The wheat production in India increased over the past three decades by combining the use of

improved varieties, fertilizers, irrigation, mechanization and improvement of market functioning (Figure 1). As against this the production of oilseeds increased by management of inputs, price and associated aspects (Figure 2). Therefore, there is no reason as to why the developing countries could not acquire food sufficiency at the national or regional basis. The international community should be talking of this rather than telling the developing countries that they have to mainly depend on imports. In conclusion, without going into details the following is required:

- I) The developing countries should not take the projections based on trade models of food security by any agency without scrutinizing inputs and assumptions relevant to their own region and country.
- II) There is a need to assess potential production on the basis of experiments and demonstrations from the research farms, and farmers fields.
- III) There should be an effort by a group of countries in a region to develop a regional food security system.
- IV) The international institutions such as FAO, CGIAR, World Bank and the international community should help developing countries become self-sufficient, preferably through research in the public institutions, and having a fair concern for environment.

Biosynthesis of selenoproteins

P. Sreenivasula Reddy

School of Life Sciences, Pondicherry University, Pondicherry 605 014, India
Department of Zoology, Sri Venkateswara University, Tirupati 517 502, India

Selenocysteine is co-translationally incorporated into the nascent polypeptide chain, in both prokaryotes and eukaryotes, through a process directed by a UGA codon. Recently it was shown that special elongation factor, novel tRNA and insertion elements at 3' non-coding region were involved in this biochemical process.

In the recent years, the importance of selenium (Se) as an essential trace element has progressively emerged due to the analysis of selenium deficiency diseases (Keshan disease and Kaschin-Beck disease) and identification of a number of selenoproteins. This element is present within proteins in the form of selenocysteine ($\text{HSeCH}_2\text{CH}(\text{NH}_2)\text{COOH}$), an analogue of cysteine in which the sulphur atom has been replaced by an atom of selenium. In contrast to random incorporation of selenomethionine in the place of methionine in proteins, selenocysteine residues occupy unique positions and are not simply cysteine replacements^{1,2}.

Ever since it was first suggested that Se is an essential component of these proteins, there has been much attention for the mode of incorporation of the Se moiety into the proteins, which occurs by a co-translational process³. With the exception of thiolase and selenoprotein P, glutathione peroxidase, bacterial formate dehydrogenase, Type I iodothyronine deiodinase, protein PA of glycine reductase complex are known to contain selenocysteine, which is also involved in the catalytic function of the above.

Biosynthesis of selenocysteine: the 21st amino acid

Sunde and Evenson⁴ identified serine as the ultimate source of carbon for selenocysteine, and proposed that an additional metabolic step involving the replacement of the phosphate of phosphoserine with selenol (Se-H) group, either while phosphoserine is esterified to the tRNA or perhaps after phosphoserine incorporation into the polypeptide chain, would lead to the synthesis of selenocysteine.

Synthesis of selenocysteine

Serine \longrightarrow Phosphoserine \longrightarrow Selenocysteine

Expansion of genetic code

Chambers and associates⁵ showed selenocysteine, found in the active site of glutathione peroxidase, is encoded by a TGA codon. The existence of a TGA codon in the middle of otherwise an open reading frame was also reported for Type I iodothyronine deiodinase⁶. Berry *et al.*⁶ constructed deletion mutants and frame shift insertions and confirmed that the putative stop (TGA) codon is in-frame, corresponding to selenocysteine. Zinoni *et al.*⁷ also demonstrated an in-frame UGA opal nonsense codon, which directs the incorporation of selenocysteine in the formate dehydrogenase gene. A multiple selenocysteine containing protein, selenoprotein P from rat, was characterized^{8,9} and the corresponding gene¹⁰ sequences were shown to contain ten TGA codons in the open reading frame. Three in-phase TGA codons were also identified in the gene encoding the mitochondrial capsule selenoprotein from mouse sperm¹¹. These results suggest that incorporation of selenocysteine into these proteins can occur by suppression of the UGA codon.

Novel tRNA

The existence of two UGA suppressor tRNAs that can carry phosphoserine in mammalian, avian and xenopus species was demonstrated^{12,13}. Tappel *et al.*^{14,15} identified a tRNA in rat liver that is specific for selenocysteine insertion. Leinfelder *et al.*^{16,17} discovered the *sel C* gene from *E. coli*, encoding an unusual seryl tRNA with UCA at the anticodon loop. This tRNA deviated in several positions from sequences previously considered

REVIEW ARTICLES

invariant in other tRNA species¹⁸ and is the longest tRNA species with 95 nucleotides, with an acceptor stem of 8 base pairs¹⁸. The novel tRNA accepts L-serine and cotranslationally inserts selenocysteine by recognizing the 'specific' UGA codon. The serine residue, which is attached to unique tRNA^{uca}, is converted to selenocysteine in a reaction dependent on the *selA* and *selD* gene products^{19,20}. This is considered another important pathway for providing additional amino acids like the formylation of methionine attached to the prokaryotic initiator tRNA²¹ and the conversion of glutamate to glutamine during the synthesis of glutamyl tRNA in several organisms²².

Unique translational factor

Forchhammer *et al.*²³ discovered a unique translation factor (SELB), the *selB* gene product, exhibiting extensive homology with sequences of translation initiation factor-2 (IF2) and elongation factor Tu (EF-Tu). Furthermore, purified SELB protein binds guanine nucleotides in a 1:1 ratio and specifically complexes with selenocystinyl tRNA^{uca}. Thus, SELB could be an amino acid-specific elongation factor, replacing EF-Tu in a special translation step. A relevant question for understanding translation and the evolution of the genetic code is, how the translational machinery can cope with the situation that one and the same triplet codon can signal either chain termination or selenocysteine insertion?

Context effects

Bock *et al.*^{24,25} made deletions in *E. coli* formate dehydrogenase gene and fused in-frame to the *lacZ* reporter gene. Their analysis revealed that a sequence of 40 bases in the mRNA at the 3' side of the UGA codon can be folded into a putative hair pin structure, and is required for selenocysteine incorporation. Mutagenesis of the hair pin structure showed that sequences of the loop region are particularly important and serve as a recognition element for special elongation factor, directing the selenocysteine-inserting tRNA species to decode a particular UGA.

Similar structures are conserved in the 3' untranslated regions in many, albeit not all, selenoprotein mRNAs²⁶. Shen *et al.*²⁷ abolished selenocysteine insertion to glutathione peroxidase by deleting four nucleotides at the 3' untranslated region of glutathione peroxidase gene and suggested hairpin-forming region was essential for translational insertion of selenocysteine at a UGA codon. Similar functional elements in the 3' untranslated region of the rat selenoprotein P mRNA, with predicted stem-loops were observed^{28,29}. Footprinting experiments

showed that a special elongation factor, SELB binds specially at the loop region of the hairpin structure³⁰. The targeted insertion of selenocysteine is accomplished by the recognition and binding of ternary complex (special elongation factor and charged novel tRNA) to the mRNA insertion elements in the immediate neighbourhood of in-frame UGA codon^{30,31}. Removal of insertion elements from the 3' end leads to termination of protein at the UGA codon.

Expression of gene during selenium deficiency

Western blot analysis for the detection of immunoreactive protein in liver cytosol obtained from rats fed on selenium deficient diets revealed that glutathione peroxidase protein was not expressed³². Northern blot analysis confirmed three-fold induction of mRNA coding for glutathione peroxidase in livers of selenium-deficient rats^{33,34}. These results indicate that mRNA is synthesized and accumulated to elevated levels in tissues of rats fed on selenium-deficient diets and that selenium status appears to regulate the translation of selenoproteins.

Conclusion

As we trace the pathway of the development of our understanding of biosynthesis of selenoproteins, several interesting features emerge – 'extra' coding capacity by UGA codon³, diversified tRNA¹⁸, existence of specific elongation factor²³, insertion elements in non-coding region^{29,30} and elucidation of selenocysteine as being the 21st amino acid³⁵ – making the protein-synthesizing system a more flexible one. What more surprises could the selenoprotein molecule hold?

Hormones, cytoskeletal proteins and cell shape

P. D. Gupta and Nandini Rangaraj

Centre for Cellular and Molecular Biology, Hyderabad 500 007, India

Recently attention has been focussed on the molecular mechanisms involved in cell shape changes brought about by chemical signals through cell surface proteins. The shape of any given cell type is maintained by various components of the cytoskeleton (microfilaments, intermediate filaments and microtubules), the extracellular matrix, the plasma membrane and associated proteins. Hormones and growth factors regulate the expression and post-translational modifications of these proteins which in turn depend on the phenotype of the cell. Action of hormones and growth factors on cells is also dependent on various factors such as phase and age of the cell, ion gradient and presence or absence of specific receptors at the right sites. The cause and effect in regulation of cell shape is not yet very clear.

THE change in cell shape can be considered as a primary adaptation of the cell to suit altered physiological de-

mands. Cell shape changes are manifestations in many of the cellular events such as division, differentiation, transformation and death. A variety of observations suggest that cell shape changes exert specific effects on gene expression¹. The exact mechanisms by which changes in cell shape affect the pattern of gene expression are not yet very clear but the cytoskeleton seems to play a key role in this process^{2–4}. To understand functional and spatial relationship of the cell in a given tissue, it is necessary to know how the local microenvironment acts on the cell to regulate its phenotype. Cell phenotype is controlled by restructuring the cytoskeletal framework which in turn depends on interactions with neighbouring cells and extracellular matrix (ECM)^{5–8}. A host of extracellular and intracellular proteins are involved in shaping the cellular architecture. The extracellular matrix proteins such as collagen, fibronectin, laminin, proteoglycans and fibrinogens⁹, the transmembrane proteins such as integrins, cadherins¹⁰, the cyto-

plasmic cytoskeletal proteins, microfilaments (MFs), intermediate filaments (IFs) and in some instances microtubules (MTs) which are sites for immobilizing signaling molecules, regulatory enzymes and metabolic substrates transduce the message to the nucleus¹¹. Various factors namely hormones, growth factors (GFs), tumour promoters are known to regulate the expression and/or the activity of many of the above mentioned proteins. These hormonally regulated proteins modulate cytoarchitecture of the target cells¹²⁻¹⁵. Altering the cytoskeletal structure may in turn change the availability of regulatory and catalytic sites of key signal transducing molecules.

During the various physiological processes, the cells undergoing altered cell morphology receive signals from the exogenous chemical factors and through different cell-signalling molecules present at the membrane and in the cytoplasm the information is transmitted to the nucleus where in coordination with internal signals, induction of specific gene expression takes place^{16,17}.

The study of mechanisms involved in the regulation of cell shape change and gene expression by various factors is an active field of research. Hormones and GFs are known to affect the expression, synthesis and post-translational modifications of cytoskeletal proteins. Plasma membrane fluidity is also known to change due to hormone treatment and change in fluidity is known to affect surface projections and regions of attachment of cytoskeletal elements to plasma membrane^{18,19}. Modulation of cytoskeletal proteins and plasma membrane constituents by hormones is responsible for change in cell shape followed by altered gene expression. In attempting to understand the genomic effect brought about by cytoskeletal proteins, Puck and Krystosek²⁰ have shown that during reverse transformation there is an increased sensitivity of DNA to hydrolysis by DNase I in the presence of the factors such as cyclic AMP, retinoic acid and nerve growth factor (NGF). They observed in the ovary derived normal fibroblasts and cyclic adenosine monophosphate (cAMP) reverse transformed chinese hamster ovary cells (CHO-K1) a clear region of DNase I sensitive DNA around the nuclear periphery. In malignant cells specific differentiation genes were sequestered and therefore could not function and exposed regions were not observed. It was also found that the cytoskeletal disorganizing agents such as colcemid and cytochalasin B prevented the basic feature of reverse transformation in enhanced genome exposure, that is closely linked to the transcriptional activation of certain genes. Cytoskeletal proteins such as the IFs and nuclear lamins seem to be actively involved in increased genome exposure, bringing about altered cell morphology.

The various factors (such as hormones) affecting cytoskeletal organization and the non-genomic and genomic pathways involved in bringing about alterations in cell shape are briefly described in this review.

Regulators of cell shape

An analysis of mechanism of shape determination reveals that the ECM and cytoskeleton are the principal determinants of cell shape^{5,7,8,21}. The ECM by itself can influence the shape of a cell. Cells grown on ECM substrate have cell shapes, proliferation rates and responses to GFs which differ from cells grown on plastic or glass²². For instance, granulosa cells cultured on plastic become flattened in shape and develop stress fibres but when grown on ECM the cells become round and closely resemble their counterparts *in vivo*¹². Similarly mouse mammary epithelial cells become cuboidal and increase milk protein synthesis when grown on floating collagen gels²³ as compared to cells on plastic or collagen coated plastic²⁴. It is now generally accepted that there is a physical link between the extracellular matrix and the cytoskeleton. The link is established with the interactions of the ECM via their cell surface receptors to the actin cytoskeleton. Many of the receptors for ECM proteins such as collagen^{25,26}, fibronectin and their receptors integrins¹⁰ and laminin²⁷ have been isolated and these receptors are linked to the actin cytoskeleton within the cell. Fibronectin and collagen are known to be involved in hormone-induced responses^{28,29}.

Changes in cell shape also involve reorganization of the cytoskeletal elements – MFs, MTS and IFs. The use of inhibitors of cytoskeletal protein polymerization such as cytochalasins, colcemid, vinblastine and nocodazole has proved beyond doubt that MFs and MTs are actively involved in change in cell morphology³⁰⁻³³. Many hormones, growth factors and tumour promoters are known to alter cell morphology by affecting the assembly/disassembly of cytoskeletal proteins^{12,14,32,34}.

The ability of actin to polymerize/depolymerize enables the cell to rearrange the MF organization. Anchorage-dependent cells adhere tightly to the underlying substratum through focal adhesions. In many cultured cells, large bundles of MFs are prominent at focal adhesion points³⁵. Many characteristics reveal that they are structurally and functionally equivalent to adhesions made by the cell to ECM *in vivo*³⁶. The actin cytoskeleton is linked to plasma membrane proteins, adhesion plaque proteins and to cytoskeletal proteins (Figure 1). Factors affecting actin or actin-associated proteins can also bring about change in organization of the cell.

The rounding of granulosa cells on treatment with follicle stimulating hormone (FSH) was reported to be associated with down-regulation of synthesis of adherens junction proteins, namely α -actinin, actin and vinculin¹². Lomri and Marie^{14,34} found that parathyroid hormone (PTH) elicited an increase in synthesis of actin in cultured mouse osteoblastic cells. Actin assembly/disassembly was found to be regulated by the expression of actin and vinculin by a feedback loop in 3T3 and HeLa cell lines. In cells which showed elevated

levels of depolymerized actin, the actin mRNA was found to be reduced³⁷.

The IFs are also known to be involved in cell shape changes. For example, upon stimulation of MCF-7 cells (human breast cancer cell line) by estradiol an increase in the keratin filament network results into cytoplasmic ridges on the cell surface^{38,39}. In primary cultures of rat vaginal epithelial cells (VEC) on addition of estradiol, Vijaysaradhi *et al.*⁴⁰ found long microridges on the cell surface which are characteristic of cornified cells indicating increased keratin network just below the plasma membrane. Phorbol esters known to mimic hormone action also bring about cell shape changes during transformation. A reorganization of cytokeratins along with disruption of junctional complexes was observed when Madin-Darby bovine kidney (MDBK) cells were treated with tetradecanoyl phorbolacetate (TPA)⁴¹. Microtubular rearrangement was found in rat pheochromocytoma cells upon activation by NGF⁴². Tubulin synthesis increased by two-fold in response to NGF whereas the synthesis of microtubule associated

protein (MAP) and Tau increased 20-fold. Increased synthesis of tubulin and other MAP proteins are associated with changes in organization of MTs⁴³. These studies suggest a link between changes in cell growth, differentiation, configuration and cytoskeletal protein synthesis.

Regulation of cytoskeleton and associated proteins

Extracellular and membrane proteins

The cytoskeletal elements are in close association and are capable of interacting with each other and with the transmembrane proteins. The ECM transduces a series of signals to the nucleus through cytoskeletal elements. This mechanism of signal transduction may be the result of mechanochemical and/or biochemical processes. In the mechanochemical process the cytoskeleton may regulate gene expression by interacting with the nuclear matrix which may lead to physical expansion of nuclear pores, thereby increasing the rate of nuclear transport in

Figure 1. Schematic diagram of two cells depicting the association between cytoskeleton and ECM at focal adhesions; the desmosomes which form another link between two adjacent cells are connected to the cytokeratin IF. Integrins, the receptors for ECM proteins such as fibronectin are connected to actin filaments through two distinct linkages. Talin–vinculin–tensin form one bridge while α -actinin forms another. The actin filaments appear to be connected to IFs and MTs via the MAPs and IFAPs (plectin). The cadherins which connect two cells are linked to actin via the β -catenin/plakoglobin- α -catenin and α -actinin. FAK, focal adhesion kinase; PY, phosphotyrosine; IF, intermediate filament; MT, microtubule; MAP, microtubule associated proteins; Pg, Plakoglobin; β cat, β -catenin; α cat, α -catenin; α A, α -actinin; V, vinculin.

spreading cells⁴⁴. Signals from the ECM reach the nucleus by a series of enzymatic events at the plasma membrane level which in turn involve cytoskeletal elements to convey the message to the nucleus. Among the prominent plasma membrane proteins associated with actin are the cadherins and integrins. Cadherins, calcium dependent-cell adhesion molecules, are transmembrane proteins that interact with cytoplasmic proteins called catenins (α and β -catenins). Catenins link cadherins to the actin cytoskeleton⁴⁵ (for more details, see the legend of Figure 1). It is evidenced by the fact that the cells which express cadherins but lack catenins are of non-adherent type^{46,47}. Cadherins through interactions with catenins form adherens type cell junctions in epithelial cells^{48,49}. β -catenin or plakoglobin constitutes a bridge between cadherins and N-terminal domain of α -catenin. α -catenin then connects this membrane-associated complex with actin cytoskeleton either directly or indirectly via α -actinin⁵⁰. It is suggested that the control of equilibrium levels between free and bound pools of catenins could play a role in regulating cellular responses to extra-cellular signals for cell-cell adhesion or cell proliferation. It seems the phosphorylation and dephosphorylation of catenins regulate the ratio of free and actin bound cadherin-catenin complexes, thereby regulating the adhesive forces of cadherins⁵¹. Desmosomal cadherins, the desmocollin and desmoglein are connected to the IFs via desmoplakin and band 6 protein in contrast to other cadherins which are connected to actin filaments directly⁵⁰.

Integrins which act as receptors for many extracellular proteins, such as collagens, laminin, entactin, fibronectin, vitronectin and fibrinogen, are associated with the actin cytoskeleton inside the cell⁵². Integrins appear to be connected to actin filaments through two distinct linkages. Talin, vinculin and the actin-capping protein tensin form one bridge, while the actin filament cross-linking protein α -actinin forms another (Figure 1; see refs 52, 53). The integrins are essential for cell adhesion both *in vitro* and *in vivo*^{54,55}. Integrins have a role as signalling receptors where they effect the release of second messengers due to hydrolysis of phosphatidylinositol 4,5 biphosphate (PIP₂) which requires both adhesion of cells to ECM and binding of platelet derived growth factor (PDGF) to its receptors. Clustering of integrins in focal adhesions triggers activation of a phosphatidylinositol phosphate (PIP)-5-kinase that catalyses phosphorylation of PIP to PIP₂ and clustering of PDGF receptors by PDGF triggers the activation of phospholipase C (PLC). When cells receive both these stimuli, significant breakdown of PIP₂ occurs, causing release of second messengers such as inositol triphosphate (IP₃) and diacylglycerol (DAG) (Figure 2)^{52,56}. Streuli *et al.*⁵⁷ demonstrated that mouse mammary epithelial cells can direct β -casein gene expression in the presence of prolactin (PRL) and laminin, a compo-

nent of the basement membrane. A cooperative signalling through integrins and PRL receptor is necessary for the differentiated phenotype. These examples demonstrate that adhesion to ECM proteins enhances responsiveness of certain cells to hormones.

Adhesion plaque proteins

The expression and post-translational modifications of adhesion plaque proteins such as vinculin and α -actinin regulate cell adhesiveness. Decreased expression of vinculin or its phosphorylation may result in an inefficient assembly of adhesion plaque proteins leading to decreased adhesion^{12,58}. On the other hand, increased synthesis of vinculin may facilitate more efficient recruitment and assembly of adherens junction proteins leading to increased tightness of adhesion and decreased motility of the cell⁵⁹. α -actinin known to cross-link MFs is also involved in binding actin filaments to the membrane. Increased level of α -actinin at the junctions leads to more stable MF-membrane interaction and hence increased tightness of adhesion⁶⁰.

Many extracellular factors induce phosphorylation of focal adhesion proteins at tyrosine residues^{61,62}. For example, binding of cells to fibronectin and stimulation by neuropeptides results in tyrosine kinase p125^{FAK} (focal adhesion kinase) phosphorylation⁶³. Substrates for activated p125^{FAK} include paxillin and tensin, the components of focal adhesion plaques. Overexpression of FAK-C-terminal domain suggests that FAK may regulate focal adhesion assembly via protein-protein interactions^{64,65}.

Microfilament proteins

Cell surface appendages like microvilli and microridges are supported mainly by MF proteins such as actin. Actin MFs are prominent at focal adhesions and are linked to integrins in the plasma membrane via talin, vinculin, tensin, α -actinin and zyxin^{52,66}. Structural changes in actin and plasma membrane components during cell division, transformation and cell death bring changes in cell shape. Luciano *et al.*⁶⁷ have shown that during the apoptotic programme of enterocytes, the MFs supporting the microvilli at the terminal web region and zonula adherens are withdrawn due to depolymerization of actin and therefore bands of microvilli are detached from main cell body and cell attains a rounded morphology.

During the G-1 phase of the cell cycle, certain types of cells in culture show large number of microvilli, blebs and ruffles which diminish on the onset of S phase and finally the cells become relatively smooth. The microvilli increase in number during G2 phase as cells thicken in anticipation of rounding up for mitosis. MFs reorganize as cells round up for mitosis and provide

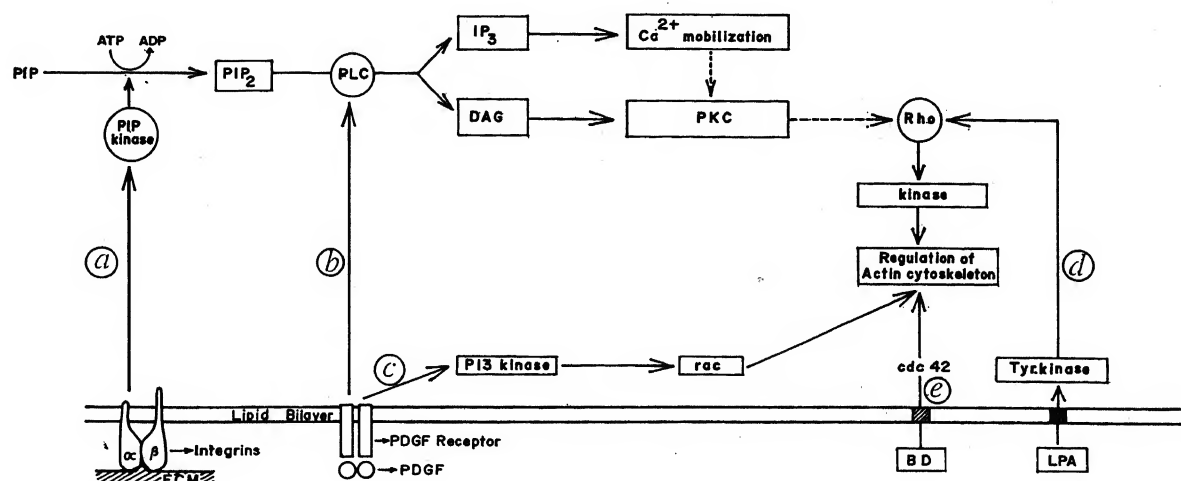

Figure 2. The various signal transduction pathways regulating actin cytoskeleton in Swiss 3T3 fibroblast cells. The ligand-receptor complex transduces the message to the rho family of small GTP-binding proteins via specific kinases. Some of these kinases are phosphatidylinositol 3-kinase (PI3K), protein kinase C (PKC) and tyrosine kinase. *a*, Adhesion of cells to ECM via the clustering of integrins triggers PIP kinase resulting in increased levels of PIP₂; *b*, Binding of PGDF to its receptor activates PLC resulting in calcium mobilization and PKC activation. Rho may be present downstream of PKC regulating actin polymerization; *c*, PGDF and insulin stimulate rac via PI3K which affects actin polymerization at the region of membrane ruffles; *d*, Lysophosphatidic acid (LPA) regulates rho via tyrosine kinase which affects actin polymerization at the region of stress fibres; *e*, Bradykinin (BD) acting via cdc42 affects actin in filopodia⁷⁹. Upstream of each rho family member guanine nucleotide exchange factors are needed which keep them in active form and the GTPase activating proteins (GAP) negatively regulate their activity.

contractile force during cytokinesis⁶⁸. So also mitogenic hormones such as estradiol prepare the cells to divide by causing the cells to shed off microvilli and cells round off in the basal layer of vaginal epithelium of rat^{4,69}. During the process of differentiation, cuboidal basal cells transform to flattened cells with an increase in fluidity of the plasma membrane⁷⁰. During both the processes, cell division and cell death, cell surface appendages are withdrawn, the contact points between plasma membrane and actin fibres are reduced and MF network collapses⁷¹. The levels of cholesterol and proteins on the membranes are reduced and membrane becomes more fluid⁷².

In *in vitro* experiments, stimulation of quiescent serum starved Swiss 3T3 fibroblast cells by various GFs, bradykinin or lysophosphatidic acid result in rearrangement of F-actin⁷³. Such kind of cellular responses at the plasma membrane seem to constitute distinct signalling pathways controlled by Rho family of small GTP-binding proteins such as rho, rac or cdc42 inducing formation of stress fibres, membrane ruffles or filopodia (Figure 2)⁷⁴. There is an evidence that stimulation of rac by PDGF and insulin is mediated by PI3 kinase⁷⁵. A tyrosine kinase appears to be required downstream of rho since rho-mediated induction of stress fibre formation in Swiss 3T3 cells is inhibited by tyrosine kinase inhibitor genistein⁷⁶⁻⁷⁹. Rho is also found to regulate enzymes such as phosphoinositide-3-kinase and phos-

phatidyl inositol-4-phosphate-5 kinase. Hence rho is involved in regulation of actin cytoskeleton through the formation of phospholipid intermediates⁸⁰.

Thus several signals induced by growth factors, hormones and tumour promoters have been implicated in regulating actin cytoskeleton. The classic second messengers IP₃ and DAG produced by hydrolysis of PIP₂ seem to play a role in the signalling cascade. DAG stimulates protein kinase C (PKC) and pharmacological activators of PKC, phorbol esters stimulate actin reorganization in fibroblasts^{77,81}. One of the isoforms of PKC⁸² and various other kinases of the src family and PLC have also been localized to adherens junctions. Events like PKC activation by hormones or GFs involve reorganization of vinculin, depolymerization of actin and phosphorylation of certain proteins that are important for stabilization of the MF-membrane interaction (Figure 2). Woods *et al.*⁸³ have found that PKC activation may play an important role in focal adhesion formation in the human embryo fibroblasts. IP₃ stimulates release of calcium from intracellular stores and the activity of several actin binding proteins *in vitro* has been shown to be regulated by calcium concentration⁸⁴. PIP₂ itself binds to a number of actin-binding proteins *in vitro* and inhibits their interaction with actin⁸⁵ leading to the proposal that alterations in PIP₂ levels could modulate actin organization *in vitro*⁸⁶. A linkage between actin-binding proteins and PIP₂ pathway has also been sug-

REVIEW ARTICLES

gested by Ben-Ze'ev¹. Extracellular factors alter adenylylate cyclase activity leading to change in the level of cAMP and modulating activity of protein kinase A (PKA). Activators of PKA stimulate the dissolution of stress fibres in fibroblasts, suggesting another signalling pathway in actin organization⁸⁷.

Intermediate filament proteins

In the foregoing discussion, the actin cytoskeleton is viewed extensively as a signal transducer, the organization/disorganization of which leads to changes in cell morphology and altered gene expression. It is also well known that the three cytoskeletal elements the MFs, IFs and MTs are interconnected to form a cytoplasmic network. The intermediate filament-associated protein (IFAP), plectin, has been shown to localize to focal adhesions where it seems to function as a cross-linker between IFs and actin⁸⁸.

Various experiments demonstrate that the organization of IFs is affected by hormones and growth factors, resulting in altered cell morphology and gene expression. Keratin IFs generally expressed in cells of epithelial origin, represent the most complex group of proteins in IF family. *In vivo* studies done in our laboratory suggest that the aggregation and dispersion of keratin filaments during the differentiation of rat VEC in the presence of estradiol is a consequence of successive cycles of phosphorylation and dephosphorylation of keratin polypeptides³. Modulation in intracellular levels of calcium depends on estradiol levels^{89,90} and the association of calcium-dependent cross-linking enzyme transglutaminase (TGase) with the IFs⁹¹. Keratins become relatively rigid due to phosphorylation which may facilitate cross-linking of the assembled keratins by disulphide linkages and $\Sigma(\tau\text{-glutamyl})$ lysine bonds leading to terminal differentiation of keratinocytes which assumes flattened morphology^{90,92}. Several other groups^{93,94} have demonstrated the involvement of filaggrin in the aggregation of phosphorylated keratins into filament bundles in epidermal cells.

Retinoids and progesterone diminish features of terminal differentiation and convert the cell to the secretory type. Removal of retinoids prepares the cells for terminal differentiation by inducing keratin expression at transcriptional level⁹⁵⁻⁹⁷. Many growth factors also act as modulators of IF network. EGF, transforming growth factor (TGF), keratinocyte growth factor (KGF) and cytokines can also induce alterations in cytoarchitecture. NGF is a known inducer of neurofilaments (NFs) and peripherin expression in developing neurons. Phosphorylation of NFs plays an important role in development, cross-linking and stability of the filament network with axons, this in turn regulates interactions of IFs with each other or with other cell components^{98,99}. Vimentin also undergoes alternate phosphorylation and

dephosphorylation with a looser network resulting from phosphorylation. In MCF-7 cells, a looser network of vimentin type IF is seen on estradiol treatment. It has been shown that norepinephrine induces conversion of flat sertoli cells into stellate morphology resulting from phosphorylation of vimentin¹⁰⁰. Ben-Ze'ev⁴¹ followed the regulation of synthesis of cytokeratin and desmoplakin, the proteins involved in the construction of desmosomal junctions. Along with the disruption of the desmosomes and reorganization of cytokeratins there was a dramatic decrease in the synthesis of cytokeratins and desmoplakin in the TPA-treated MDBK cells. However, Gupta *et al.*⁴ found that during keratinization of VEC, cellular connections were many fold higher in estradiol primed immature rats with increased keratin synthesis in the intermediate layers. The regulation of vimentin type IF which is coexpressed in MDBK cells was different from that of keratins and this may be due to spreading of cell on the substrate.

Microtubule proteins

Rosette and Karin¹⁰¹ have provided evidence to show that MT depolymerizing agents activate sequence-specific transcription factors such as NF-kappa B (NF-KB) and induce NF-KB dependent gene expression in HeLa cells. In the unstimulated HeLa cells they found that majority of the NF-KB resided in the cytoplasm as a complex with its inhibitor I kappa B (IKB). Upon stimulation with nocodazole the NF-KB translocates to the nucleus with a concomitant degradation of IKB. It is known that NF-KB activity is induced in presence of TPA IL-1 and certain growth factors¹⁰² and all these agents are also known to reorganize the cytoskeleton¹⁰³. Hence there is a possibility that selective depolymerization of MTs by any of these agents could be an intermediate in the signalling pathway, leading to activation of NF-KB in turn modulating gene expression to give a differentiated phenotype.

Possible interaction between cytoskeletal proteins and genes

Recently a few authors have described the probable mechanism of mammalian gene regulation by the cytoskeletal elements^{20,104}. Gene regulation in mammalian cells seems to operate at two levels. The first step is the activation of tissue-specific genes in their conversion from the sequestered to the exposed state. This involves the transfer of the appropriate DNA from the interior of the nucleus to the region of the nuclear periphery and the necessary conformational changes and specific protein interactions that render such DNA susceptible to hydrolysis by DNase I, this in turn make genes also vulnerable to inducers, repressors and other transcriptional

factors. The second step regulates the transition of the exposed genes between active and inactive states as a result of interaction with appropriate effector molecules in the surrounding medium. About 30% of the genes in mammalian cells is converted from sequestered to exposed state in a single action by cAMP, retinoic acid and NGF on transformed cells. Puck and Krystosek using Chinese hamster ovary cells²⁰ have shown that cytoskeleton network is a necessary structure in producing the specific genome exposure pattern for each cell type. It should also be noted that genome exposure is necessary but not sufficient condition for gene activation.

The mammalian cell cytoskeleton thus becomes part of an information transmission system extending from the cell membrane to its specific receptor sites through the cytoplasm and terminating in specific points on each chromosome so that specific domains of exposure and sequestration result.

Conclusion

The structural and functional integrity of a cell is maintained by the cytoskeletal network, cytoskeletal-associated proteins and the extracellular matrix proteins. Fibronectin, laminin, collagen which are regulated by hormones are connected to the actin cytoskeleton via their transmembrane receptors. The actin network is in turn linked to IFs and MTs. A coordination between these various components is necessary to maintain a definite cell shape in a given physiological condition. For instance, disruption of cytoskeletal-ECM linkage in skeletal muscle leads to sarcolemmal instability, muscle cell necrosis resulting in muscular dystrophy¹⁰⁵. In experiments with xenopus embryos, introduction of mutant E-cadherins into embryos resulted in ectodermal lesions at the beginning of gastrulation, later causing disruptions in early epidermal development¹⁰⁶. Expression of mutant N-cadherin (N-neural) lacking the ectodomain resulted in general inhibition of adhesive interaction in the embryo¹⁰⁷. Similarly disruption of cytokeratin expression during development of xenopus embryo resulted in defective gastrulation. Blessing *et al.*^{108,109} have shown that correct IF can be of critical importance for the function and stability of a given cell type.

Hormones affect their target cells during cell growth, division, differentiation, transformation and apoptosis. The mechanism involved in the cell shape change during these processes is still not clear, however, hormones are known to regulate ECM proteins which effect cytoskeletal membrane interaction bringing about altered cell morphology. The cytoskeletal associated proteins help in the polymerization/depolymerization of the cytoskeleton elements. The cytoskeleton network is an active site for signal transduction pathways. The various molecules involved in these pathways are coming to light and a

clear-cut pathway involved in hormone-induced cell shape changes is yet to be identified. However, the role of cytoskeleton, their associated proteins and ECM is well established, but how these different components coordinate to maintain a definite cell shape in a given environmental milieu is still an active field of research.

MEETINGS/SYMPOSIA/SEMINARS

Third National Seminar on Malaria and Other Tropical Diseases

Date: 18–20 February 1997
Place: Bangalore

Topics include: Genetics and cytogenetics of insect vectors, Physiology and biochemistry; Radiation and autoradiography, Ecology and ethology, Insecticide resistance; Speciation and evolution, Chemotherapy and Immunology, Vector control – genetic, biological and chemical. Social and economic research; other related studies (insect pests of plants and animals). Epidemiology of tropical diseases; The influence of genetic and other factors on vector susceptibility to parasites; Genetic and other factors on vector susceptibility to parasites; Genetic engineering technology in vector control.

Contact: Prof. N. J. Shetty

Phone: 3355036 (Extn. 214)

Silver Jubilee Symposium of Catalysis Society of India: Thirteenth National Symposium on Catalysis

Date: 2–4 April 1997
Place: Dehradun

This symposium plans to cover all branches of homogeneous and heterogeneous catalysis. Particular emphasis will be given to novel applications in industrial catalysis related to petroleum refining, petrochemicals and fine chemicals. Other areas of interest are

catalysis in the protection of environment, C₁ chemistry, microporous materials synthesis and characterization.

Contact: Dr G. Murali Dhar
Convenor, Silver Jubilee Symposium
Indian Institute of Petroleum
PO IIP, Dehradun 248 005, India
Phone: 91–135–660113 to 660116
Fax: 91–135–621986, 621858
E-mail: gmd%iip@sinetd.ernet.in

Short Course on Aseismic Design of Structures—Random Vibration Approach

Date: 20–22 May 1997
Place: Bangalore

Course is designed to provide a fundamental understanding of the seismic hazard analysis, theory of random vibrations, and their applications to seismic design of buildings and seismic qualification of secondary structures. It will be useful to: practising engineers or research professionals responsible for ensuring the seismic safety of a structural system or sub-system, other practising engineers requiring the application of random vibration principles (e.g. in the design of vehicular, aerospace and automobile systems), and teachers from engineering colleges.

Implications of increasing greenhouse gases and aerosols on the diurnal temperature cycle of the Indian subcontinent

M. Lal *, G. Srinivasan** and U. Cubasch†

*Centre for Atmospheric Sciences, Indian Institute of Technology, New Delhi 110 016, India

**India Meteorological Department, New Delhi 110 003, India

†Deutsches Klimarechenzentrum GmbH, D-20146 Hamburg, Germany

The response to transient increase of greenhouse gases and sulphate aerosols in the Earth's atmosphere on the diurnal temperature cycle over the Indian subcontinent is examined using the data generated in coupled atmosphere-ocean model experiments. The spatial distribution of changes in seasonal mean maximum and minimum temperatures over the Indian subcontinent as simulated in combined greenhouse gas and sulphate aerosol forcing experiment for the decade 1980-89 with respect to the control climate of decade 1880-89 is found to be in fair agreement with observations. An increase in annual mean maximum and minimum surface air temperatures of 0.7 and 1.0°C respectively is projected over the land regions of the Indian subcontinent in the decade 2040s with respect to 1980s. The projected rise in maximum temperature is found to be most pronounced during the monsoon season while the rise in minimum temperature has its peak during the post-monsoon months over the region. A significant decrease in the diurnal temperature range over the Indian subcontinent during winter and no appreciable change during the monsoon season is suggested for the future.

ONE important aspect of the observed temperature change relates to its asymmetry during the day and night. Observed warming in surface air temperatures over several regions of the globe have been reported to be associated with increase in minimum temperatures (accompanied by increasing cloudiness) and decrease in diurnal temperature range¹⁻³. General circulation model simulations with increasing concentrations of CO₂ in the atmosphere have also shown pronounced increase in minimum temperatures and decrease in diurnal temperature range^{4,5}. The Indian region provides an interesting case in that while the observed mean surface air temperatures over India have been reported to exhibit a warming trend close to the global and hemispheric trends⁶, an increase in diurnal

temperature range accompanied with increasing maximum temperatures and relatively steady minimum temperatures have been reported over many parts of India⁷. In a study, Hansen *et al.*⁸ reported that the observed changes of the diurnal cycle result from a combination of local negative forcing due to sulphate aerosols over continental regions and globally-distributed positive forcing due to greenhouse gases. Model simulations of diurnal temperature range are also sensitive to parameterization of physical processes as changes in diurnal temperature range could result from changes in atmospheric water vapour, cloud optical properties, cloud cover and land surface properties. We examine here the influence of sulphate aerosols on the simulation of maximum and minimum temperatures over the Indian subcontinent using the data from a series of recent coupled climate model experiments (performed at Deutsches Klimarechenzentrum, Germany with greenhouse gas forcings as well as combined greenhouse gas and sulphate aerosol forcings). Lal *et al.*⁹ have demonstrated that the model experiment with combined greenhouse gas and sulphate aerosol forcings replicates the observed changes in surface air temperatures over the Indian subcontinent during the past century.

We discuss here the salient findings of our analysis on a comparison of area-averaged (land regions only) observed and model-simulated trends in maximum and minimum surface air temperatures and diurnal temperature range over the Indian subcontinent for the period from 1880s till 1980s. A comparison of regional trends in maximum and minimum temperatures as simulated by the model and those observed over the past century provides a potentially stringent test of the model's credibility. A comparison of the spatial distribution of observed and model-simulated changes in maximum and minimum temperatures over the region is made. A plausible future scenario of changes in maximum and minimum temperatures and diurnal temperature range for the Indian subcontinent is also presented here.

The model experiments and region of interest

The present study is based on analysis of data generated in numerical experiments performed with the European Community *HAM*burg. (ECHAM version 3) atmospheric model coupled to a Large Scale Geostrophic ocean model (hereafter referred to as ECHAM3+LSG model) at T-21 resolution. ECHAM3 is the third generation atmospheric general circulation model used for global climate modelling investigations in Germany. The LSG ocean model is based on a numerical formulation of the primitive equations appropriate for large-scale geostrophic motion. The ECHAM3 and LSG are coupled by the air-sea fluxes of momentum, sensible and latent heat, short and long wave radiation and fresh water¹⁰. For further details on the model, the reader is referred to Lal *et al.*⁹, Maier-Reimer *et al.*¹¹ and DKRZ¹².

In the first experiment (hereafter referred to as C), the control reference atmosphere has been simulated with the coupled climate model over a 170 year period (1880–2049) with constant levels of atmospheric CO₂ concentration and no anthropogenic sulphur emissions. The second experiment (hereafter referred to as G) included the observed changes in atmospheric equivalent CO₂ (CO₂ and other greenhouse gases) concentrations for the period 1880–1989 and the projected increase (based on *Business-as-usual* scenario of IPCC¹³ and representing a ~1.3% per year compound increase of CO₂) in equivalent CO₂ concentrations for the period 1990–2049. In the third experiment (hereafter referred to as S), the effects of both the greenhouse gases (equivalent CO₂) as well as the sulphate aerosols were considered. The anthropogenic sulphate burden information was obtained from Langner and Rodhe's calculations¹⁴ and the direct radiative forcing was mimicked by a change of the surface albedo following the algorithm developed by Charlson *et al.*¹⁵ The global mean sulphate forcing increased continuously since 1880s, and more rapidly from 1950 onwards. The spatial distribution of sulphate loading for the present-day atmosphere and that expected by the middle of next century over the Indian subcontinent are given in Lal *et al.*⁹

The geographic region of interest for our data analysis reported herein was mainly confined to the region bounded by ~5°N to 30°N latitude and ~65°E to 95°E longitude (Indian subcontinent and adjoining seas). It may be noted that, in spite of the fact that the horizontal resolution in the ECHAM3+LSG model experiments stated above is rather coarse (5.625° latitude, × 5.625° longitude), the model has demonstrated⁹ reasonable skill in simulating the monsoon circulation and the seasonal cycle of observed climatology for the region.

Comparison of past observed and simulated regional diurnal temperature cycle

Observed and model-simulated trends in maximum and minimum temperatures

Analysis of the recent simulated global and Northern Hemispheric mean near-surface temperatures has proved that an anthropogenic climate change signal in observed records of near-surface air temperature change can be detected at 95% confidence level¹⁶. The study also suggests that model-simulated past trends in global mean surface warming can be reconciled with the observed warming trends only when the cooling effect of aerosols on climate is accounted for. In order to place a high degree of confidence in future climate change, climate models must replicate the past trends in key climate elements within the limits of natural variability. In this respect, the year-to-year variability in model-simulated surface air temperature and monsoon rainfall over the Indian subcontinent has been found to be in fair agreement with the observed climatology⁹.

Figure 1 depicts the 5-year running mean anomalies in area-averaged maximum and minimum surface air temperatures as observed⁷ for the period from 1901 to 1994 and as simulated by the model for the period 1880–2049 in experiments G and S for the Indian subcontinent (land points only). The observed series⁷ is based on spatial means of 121 stations over India while the model simulated data series is based on the spatial average of 19 land points only. On regional scales, the higher level of year to year variability obscures any systematic differences in maximum and minimum surface air temperatures simulated in experiments G and S in the first half of this century. All India mean annual maximum temperature, has a significant trend of 0.6°C/100yr in observational records while the minimum temperature is found practically trendless⁷. Both the annual mean maximum and minimum temperature anomalies in experiment G show a much higher increasing trend (0.85°C/100yr in maximum temperature and 0.84°C/100yr in minimum temperature respectively) than observed in the past century. In experiment S, the annual mean maximum temperature anomalies exhibit an increasing trend of 0.61°C during the past century which is in excellent agreement with observed trends. The annual mean minimum temperature anomalies have an increasing trend of 0.18°C during the past century in experiment S. Moreover, both the maximum and minimum temperature anomalies simulated by the model in experiment S are found to be closer to the observed anomalies in the recent years, thus signifying the importance of aerosol forcing (Figure 1). The inter-annual variability generated by the model is found to be rather large in a statistical sense as compared to that

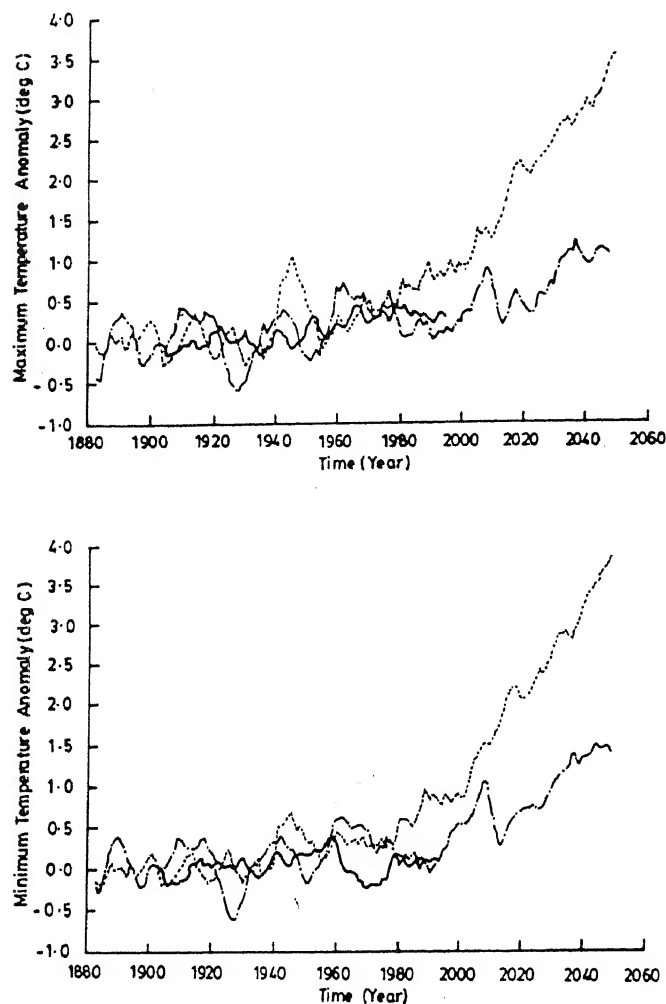

Figure 1. Observed (1901–1994) and model-simulated (1880–2049) trends in area-averaged anomalies in annual mean maximum (upper) and minimum (lower) surface temperatures (5 year running means, land regions only; °C) over the Indian subcontinent. (Solid thick line is for observed anomalies; solid thin line is for anomalies simulated in CO_2 + aerosol experiment and dotted line is for CO_2 only experiment.)

observed over the region even though we recognize that these climate model simulations do not attempt to precisely simulate individual years.

Table 1 gives the mean annual and seasonal (winter and monsoon) changes in area-averaged maximum and minimum surface air temperatures in the decade 1980–89 with respect to the decade 1880–89 over the Indian subcontinent as simulated in the experiments G and S and the observed⁷ linear trends per 100 year period. While the diurnal temperature range over the region simulated by the model in experiment G is found to decrease (during winter) or remain unchanged (during monsoon) in the past century, it has increased on seasonal as well as on annual mean basis in experiment S which is in agreement with observations (but unlike the observed and/or simulated trends over many parts of the globe).

Two important points emerge from Table 1. The first is that the minimum temperature changes simulated by the model in a season or on annual mean basis in the greenhouse gas forcing only experiment are significantly higher when compared to the observed changes over the past century over the Indian subcontinent. The increasing trends in maximum and minimum temperatures simulated in experiment S are lesser as compared to G due to negative forcing exerted by the introduction of sulphate aerosols. The combined greenhouse gas and sulphate aerosol forcing experiment is able to replicate the observed changes in maximum and minimum temperatures over the region in a broad sense on seasonal as well as on annual mean basis. The second point is that, while the differences in maximum temperatures simulated in experiments S and G are less pronounced, a relatively smaller increase in minimum temperature is simulated in experiment S as compared to G on seasonal as well as annual mean basis. This could have been induced by a reduction in high cloud amount as, in high clouds, an increase in albedo could be offset by a change in cloud infrared emissivity, leading to decrease in warming effect during the day and increase in cooling effect during the night¹⁷. This further suggests the possibility that the direct influence of sulphate aerosols (trapping of solar radiation) may not be as dominating as the indirect effect (through its influence on clouds). The general notion that an increase in cloud cover takes place due to industrial sulphur emissions³ may not be valid over the monsoon region. The significant decline in the nighttime temperatures in experiment S is supported by a reduction of about 0.8% in area-averaged fractional cloud cover in the decade 1980s with respect to the control climate of 1880s over the monsoon region. Decreased cloud cover and consequent suppressed water vapour feedback in a relatively drier atmosphere should produce lower minimum temperatures. The precise modulating role of clouds in numerical models is, however, not yet fully understood. The results from experiment S are in conformity with the observations in that both exhibit an increase in diurnal temperature range accompanied with increasing maximum temperatures over the region.

Spatial distribution of observed and model-simulated changes in diurnal temperature cycle

A comparison of spatial patterns of observed and model-simulated (Experiment S) maximum and minimum temperatures and diurnal temperature range over the region of interest for the present-day atmosphere (1980s) suggests reasonable similarity between them during both winter and monsoon seasons (Figures 2 and 3). During winter, the simulated maximum temperatures are lower and simulated minimum tem-

Table 1. A comparison of model-simulated and observed linear trends ($^{\circ}\text{C}$) per 100 years in area-averaged (land only) maximum and minimum surface temperatures over the Indian subcontinent (based on data from 1901 to 1990)

Period	Experiment G		Experiment S		Observed	
	Maximum	Minimum	Maximum	Minimum	Maximum	Minimum
Annual	0.85	0.84	0.61	0.18	0.6	0.1
Winter (DJF)	0.86	0.97	0.78	0.29	0.9	0.2
Monsoon (JJAS)	0.83	0.83	0.37	0.08	0.4	-0.3

temperatures are higher than the observed climatology (Figure 2). Consequently, the simulated diurnal range is lower than the observed. A better agreement is found between the spatial patterns of observed and simulated magnitude of maximum and minimum temperatures during the monsoon season (Figure 3). The model due to its rather coarse resolution has not been able to realistically portray the observed locations of extremes in maximum or minimum temperatures. The scanty observations limit verification of the model simulations of the diurnal temperature cycle in the Himalayan region.

In order to quantify the similarity between the observed and model-simulated spatial distribution of maximum and minimum temperatures, we performed calculations of the pattern correlation coefficient and root mean square error between the observed and model-simulated climatology of maximum and minimum temperatures for winter and monsoon season over the region of interest. For this purpose, both the observed and model-simulated data were first interpolated on to a common 2.5° square grid configuration with a cubic spline fit. The pattern correlation coefficient gives a measure of similarity of the pattern structure of the observed and simulated fields throughout the region whereas the root mean square error gives an overall measure of the absolute error in simulating the field over the region. During winter, the pattern correlation coefficient between the observed and simulated climatology is 0.61 for maximum temperature and 0.69 for minimum temperature. The root mean square error is 3.6°C for maximum temperature and 2.9°C for minimum temperature. During monsoon season, the correlation coefficients are 0.63 and 0.59 while the root mean square errors are 3.7°C and 4.1°C for maximum and minimum temperatures respectively. Keeping in view the fact that the spatial distribution of model-simulated temperatures

considered here are based on only 19 land points as against the spatial distribution of observed climatology

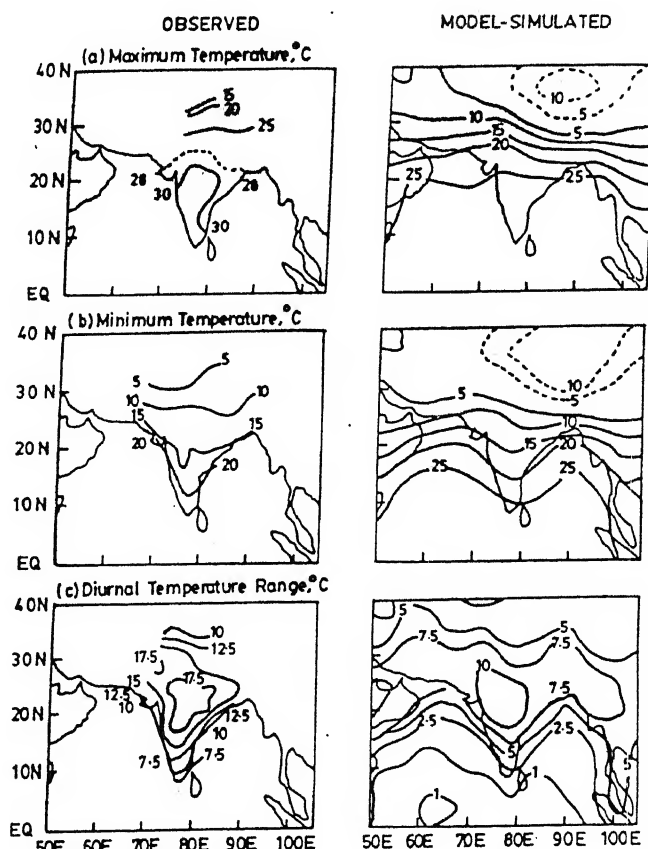

Figure 2. Spatial distribution of present-day (1980s) observed and model-simulated (under combined equivalent CO_2 and aerosol forcings) maximum and minimum temperatures and diurnal temperature range ($^{\circ}\text{C}$) over the Indian subcontinent during winter season.

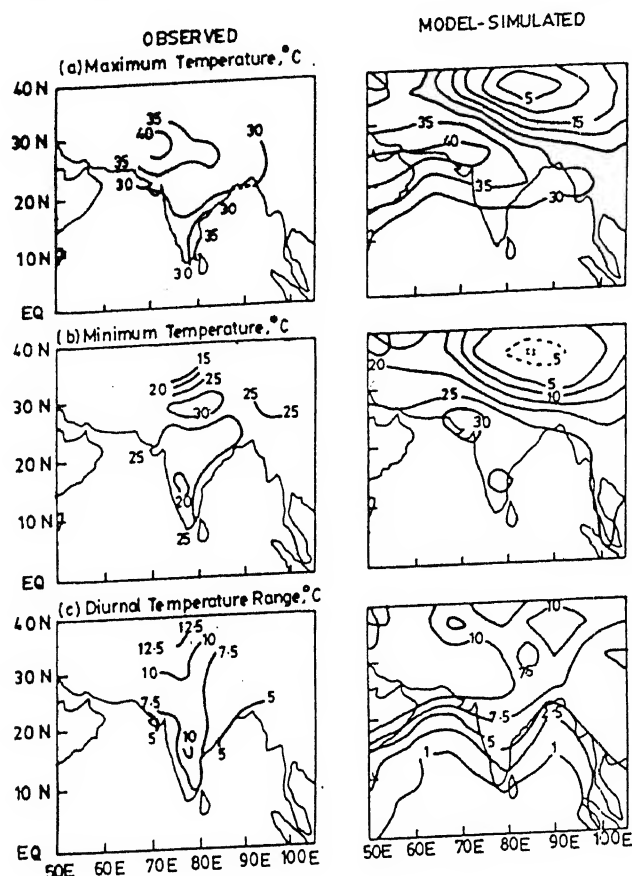

Figure 3. Spatial distribution of present-day (1980s) observed and model-simulated (under combined equivalent CO_2 and aerosol forcings) maximum and minimum temperatures and diurnal temperature range ($^{\circ}\text{C}$) over the Indian subcontinent during monsoon season.

ogy based on data from 121 stations, the pattern correlations higher than 0.6 suggest that model simulations perform reasonably well in simulating the maximum and minimum temperature patterns over the region.

The spatial distribution of observed⁶ changes in the annual mean temperatures in the decade 1980s with respect to 1880s over the Indian subcontinent suggested a rising trend in the maximum temperature at almost all stations south of 23°N and a decreasing trend north of 23°N . The minimum temperatures showed increasing trend in almost all parts of central and Peninsular India barring some pockets along west and east coasts with nominal falling trend. Decreasing trends in the simulated maximum and minimum temperatures over the north India and increasing trends over the Peninsular India in the experiment S are in fair agreement with observations (Figure 4) except in the Himalayan highlands. The differences in the highlands could be due to sparse observations and also due to coarse resolution of the model over the region. The experiment with only CO_2 forcing produced consistently higher than realized changes in maximum and minimum temperatures over

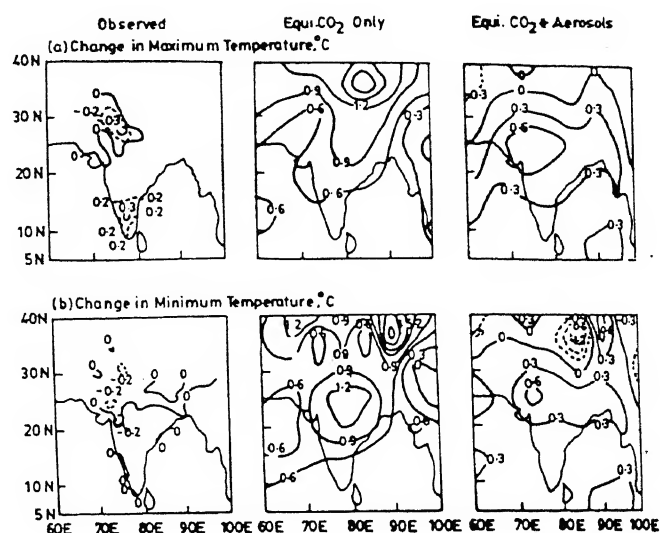

Figure 4. Spatial distribution of observed and model-simulated (equivalent CO_2 forcing and combined equivalent CO_2 and aerosol forcings) changes in annual mean maximum (a) and minimum (b) surface temperatures ($^{\circ}\text{C}$) in the decade 1980s with respect to 1880s over the Indian subcontinent.

the region on annual mean basis. The combined CO_2 and aerosol forcing is able to reproduce the observed changes in diurnal temperature cycle during the past century better than the CO_2 forcing only (Figure 4). Our findings on the future projections of regional changes in maximum and minimum temperatures and diurnal temperature range based on the combined CO_2 and aerosol forcing experiment should, therefore, have a better degree of confidence.

Future changes in diurnal temperature cycle

Table 2 gives the area-averaged annual and seasonal changes during the decade of 2040s over the Indian subcontinent in the maximum and minimum temperatures as simulated by CO_2 forcing only as well as by combined CO_2 and aerosol forcing. The projected annual mean changes in maximum and minimum temperatures in CO_2 forcing only experiment are more than a factor of two higher relative to those in combined CO_2 and aerosol forcing experiment.

In the combined CO_2 and aerosol forcing experiment, while the projected rise in maximum temperature is found to be most pronounced during the pre-monsoon and monsoon seasons, in minimum temperature it is for the post-monsoon and winter months. A decline in the diurnal temperature range is simulated by the model for the decade 2040s on annual mean basis. The projected decline in diurnal temperature range during winter is most pronounced (0.6°C) and

Table 2. Changes ($^{\circ}\text{C}$) in model-simulated area-averaged maximum and minimum temperatures (land only) during 2040s as compared to 1980s over the Indian subcontinent

Period	Equivalent CO_2		Equivalent CO_2 + aerosol	
	Maximum	Minimum	Maximum	Minimum
Annual	2.38	2.73	0.74	1.01
Winter (DJF)	2.60	2.62	0.47	1.10
Pre-monsoon (MAM)	3.23	3.15	0.87	0.99
Monsoon (JJAS)	1.61	2.50	0.88	0.88
Post-monsoon (ON)	2.32	2.96	0.64	1.17

is found to be statistically significant at 90% confidence level. During the monsoon season, no change is simulated in the diurnal temperature range for the future.

In its spatial distribution, while no significant rise in maximum temperature is expected over northeast India by the middle of next century, a rise of about 1.5°C is simulated along the western margins of India (Figure 5). A marginal decline in the minimum temperature of about 0.5°C is likely over the northeast India whereas a rise of above 1.5°C is possible along the western Indian subcontinent. The model-simulated changes in both maximum and minimum temperatures are found to be characteristically smaller over northeast India compared to rest of the region. The model results suggest a decline in diurnal temperature range ($\sim 0.5^{\circ}\text{C}$) over most parts of India due to relatively larger increase in the minimum temperature. The diurnal temperature range over northeast India may, however, increase by about 0.5°C .

Discussions and conclusion

A comparison of observed and model-simulated trends in annual mean area-averaged maximum and minimum surface temperatures suggests that the combined greenhouse gas and sulphate aerosol forcing experiment has been able to reproduce the observed changes in diurnal temperature cycle over the region during the past decades in a broad sense. The spatial distribution of changes in annual and seasonal mean, maximum and minimum temperatures over the Indian subcontinent as simulated in combined greenhouse gas and sulphate aerosol forcing experiment for the decade 1980s with respect to the control climate of decade 1880s is found to be in fair agreement with observations. Thus, the inclusion of aerosol forcings in coupled climate model experiments has

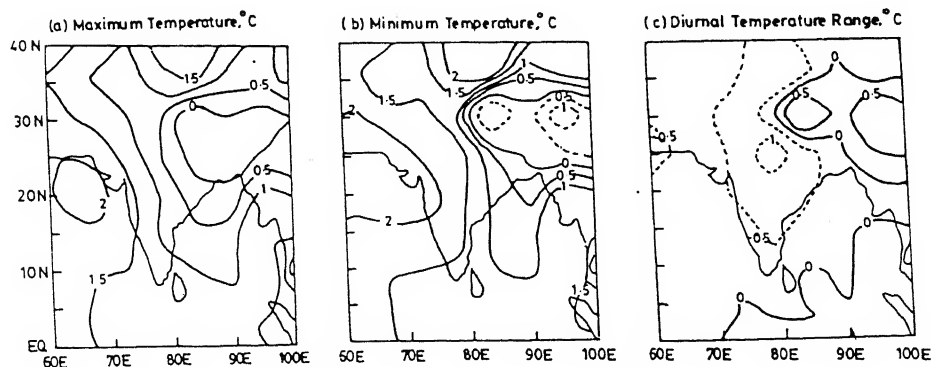

Figure 5. Spatial distribution of changes in annual mean maximum and minimum temperatures and diurnal temperature range ($^{\circ}\text{C}$) during the decade 2040s with respect to the decade 1980s over the Indian subcontinent as simulated by the model due to combined equivalent CO_2 and aerosol forcings.

RESEARCH ARTICLES

provided us some insights on how to explain, in general, the observed asymmetry in the diurnal temperature cycle over the region.

An increase in annual mean maximum and minimum surface air temperatures of 0.7 and 1.0°C respectively over the land regions of the Indian subcontinent by the middle of next century is simulated by the model taking into account the projected emission of greenhouse gases and sulphate aerosols. The projected rise in maximum temperature is found to be most pronounced during the monsoon season while the rise in minimum temperature has its peak during the post-monsoon months over the region. A significant decrease in the diurnal temperature range over the Indian subcontinent during the winter season and no appreciable change during the monsoon season is simulated. The projected changes in the maximum and minimum temperatures and the diurnal temperature range could have significant impact on the patterns of agricultural productivity over the Indian subcontinent.

The key factors that affect the regional scale performance of global climate models are the horizontal resolution and physical parameterization schemes. The coarse resolution may introduce systematic errors in the depiction of coastlines as well as high mountains with consequent effects on the simulation of regional circulation and temperatures. In this respect, the projections given here have only a limited degree of confidence. Since, at present, only the direct effects of sulphate aerosols are considered in model experiments (in terms of surface albedo), we cannot judge precisely the influence of aerosols in modulating the cloud microphysics. When the resolution of available climate models increases with the availability of enhanced super-computing power and improved parameterization schemes of subgrid-scale physical processes such as clouds are incorporated, a general increase in accuracy in regional projections may be expected.

Forcing mechanisms of the Bay of Bengal circulation

P. N. Vinayachandran, Satish R. Shetye*, Debasis Sengupta and Sulochana Gadgil

Centre for Atmospheric Sciences, Indian Institute of Science, Bangalore 560 012, India

*National Institute of Oceanography, Goa 403 004, India

A state-of-the-art ocean general circulation model, set up for the North Indian Ocean and driven by climatological wind stress simulates most of the observed features of the near-surface circulation of the Bay of Bengal. The prominent features of the annual cycle are an anticyclonic gyre with a poleward East India Coastal Current (EICC) during February–May, and an equatorward EICC during October–December. During the summer monsoon, the coastal current flows poleward in the south and equatorward in the north. To identify the principal mechanisms governing this cycle, we carried out experiments with modified winds. When spatially uniform wind stress was applied only over the Bay, the circulation is similar to, but weaker than the observed, and can be linked to two coastal Kelvin wave pulses which originate along the eastern boundary of the Bay during the summer and winter monsoons. When the Bay is forced with observed winds, the wind stress curl strengthens the poleward EICC during February–May and the equatorward EICC during October–December. The principal contribution of equatorial winds is to generate the equatorward coastal current during the summer monsoon off the east coast of India.

1. Introduction

THE Indian Ocean has a unique geographic setting; it is bounded in the north by the Eurasian Land mass. This termination of the ocean in the tropics gives rise to spectacular seasonality in the overlying atmosphere and, consequently, in the ocean itself. North of 10°S the surface winds blow from the southwest during May–September and from the northeast during November–February. The ocean is primarily driven by winds, and under the influence of the seasonally reversing monsoon winds, the circulation in the Indian Ocean reverses twice during the year.

The response of the Indian Ocean to monsoon forcing has evoked considerable interest in the past. However, most of the attention has been focused on the western part of the Indian Ocean, which has a prominent seasonally reversing current viz. the Somali Current^{1,2}. The rest of the basin has remained rather poorly observed

and little studied. This is particularly true for the Bay of Bengal, which forms the northeastern part of the Indian Ocean. The Bay is not only of great oceanographic interest but it also plays an important role in maintaining and modulating the monsoon over the Indian region.

The Bay is markedly different from the Arabian Sea in two respects. Firstly, over the Arabian Sea, evaporation exceeds precipitation and it receives highly saline water from the Red Sea and from the Persian Gulf, making the salinity of the upper layer rather high. In contrast, over the Bay rainfall exceeds evaporation and the Bay also receives a large quantity of freshwater as river discharge, leading to an upper layer of less saline water for a large part of the year³. The surface waters in the Bay have such low salinity that the stratification in the upper layer is dominated by salinity gradients rather than temperature gradients⁴.

Secondly, over a large part of the year the sea surface temperature (SST) of the Bay is above 28°C (ref. 5), which is the threshold SST for active generation of large-scale convection/precipitation⁶. On the other hand, the SST in the Arabian Sea, west of about 70°E, is below the threshold over most of the year. The SST is determined by the heat flux at the sea surface (which in turn depends on surface winds and on SST itself) and horizontal and vertical advection in the ocean. How SSTs higher than 28°C are maintained in the Bay is not yet clearly understood. Most of the low pressure systems, depressions and cyclones which give rainfall over the Indian region are generated over the Bay. The coupling of the monsoon atmosphere with the Bay must therefore play an important role in determining rainfall over the Indian region and its variability. Thus understanding the Bay is a challenging problem in the areas of ocean dynamics and coupled ocean–atmosphere systems.

During the last few years, new observations have been made in the Bay, by Shetye *et al.*^{4,7,8} in the western Bay and by Murthy *et al.*⁹ and Suryanarayana *et al.*¹⁰ in the central Bay. These and earlier analysis of ship-drifts¹¹ show a distinct seasonal cycle of surface circulation³. A prominent feature of this seasonal cycle is the seasonally reversing coastal currents. The coastal current along the

east coast of India flows poleward before the summer monsoon and equatorward during the winter monsoon season. During the summer monsoon there is a poleward current along the Indian coast in the southern part and an equatorward current in the northern part.

One of the major aims of ocean modelling studies is to simulate the observed seasonal variation in the circulation and understand it in terms of the response to the winds over the Bay as well as other regions. Both these aspects have been addressed so far using the relatively simple reduced gravity models, which assume that the ocean is made up of very few layers of which the lowest one is static. The studies of Potemra *et al.*¹² and McCreary *et al.*¹³ (henceforth MKM) have shown that major features of the surface circulation are simulated by such models. Two types of waves have been shown to play a pivotal role in the time-dependent response of the Bay to the wind-forcing. These are the Rossby waves which occur everywhere in the oceans, and the Kelvin waves, which propagate along the coast. Equatorial Kelvin waves generated by winds over the equatorial Indian Ocean propagate eastward. On encountering the eastern boundary of the ocean, a part of the energy of these waves is transferred to coastal Kelvin waves. The latter move rapidly along the coastline of the Bay of Bengal and influence the circulation in the Bay.

On the question of forcing the circulation in the Bay, different mechanisms have been proposed involving winds over the Bay, and winds over the equatorial Indian Ocean, and Rossby and Kelvin waves. Potemra *et al.*¹² highlighted the role of planetary waves in setting up the seasonal circulation. Yu *et al.*¹⁴ argued that these waves have their origin as equatorial Kelvin waves, implying that equatorial forcing alone can set up the observed annual cycle. MKM¹³ highlighted the importance of coastal Kelvin waves and Rossby waves generated entirely in the Bay by local alongshore winds. Shetye *et al.*⁷ have emphasized the role of winds over the open Bay. Recently, Shankar *et al.*¹⁵ and McCreary *et al.*¹⁶ have examined the roles of different mechanisms in an analytic model and in numerical experiments.

In this paper we address the problem of understanding the relative roles of different mechanisms in driving the circulation of the Bay using a state-of-the-art ocean general circulation model (OGCM) developed by Bryan¹⁷ and Cox¹⁸. While general circulation models of the atmosphere have been used in our country for several years, this is the first implementation of an OGCM. We report the results of several experiments carried out with the Bryan-Cox model with two objectives. The first is to see how well the known features of the near-surface circulation in the Bay are reproduced when climatological monthly mean winds force the model. Second, we carry out numerical experiments aimed at constructing a simple, yet dynamically correct, picture of circulation in the Bay. These experiments also permit us to estimate the

contribution of different mechanisms in driving the circulation in the Bay. The model set-up is briefly described in section 2. Section 3 discusses the annual cycle, comparing the model results with ship-drifts. Sensitivity of the model to horizontal resolution is examined in section 4. In section 5 the results of model runs with modified wind fields are examined. Section 6 summarizes the main findings.

2. The model set-up

The Bryan-Cox model, now commonly known as the Modular Ocean Model¹⁹, solves the primitive equations on a finite difference grid using the method of Bryan¹⁷. The model domain for the present study lies between 20°S–25°N and 40°E–100°E, with a no-slip condition on all boundaries. The horizontal grid spacing is 1° in both zonal and meridional directions. There are 15 levels in the vertical, of which 8 are in the top 100 m (Table 1). We have also made a run with a grid spacing of 1/3° to test the sensitivity to horizontal resolution.

Horizontal diffusivity and viscosity are set to $5 \times 10^7 \text{ cm}^2 \text{ s}^{-1}$. The scheme of Pacanowski and Philander²⁰ is used for vertical mixing. The model has realistic coastline geometry and topography as resolved by the Scripps topography²¹. The model is started from a state of rest with initial conditions for temperature and salinity obtained from the Levitus²² climatology for January. At the surface the model is forced by the climatological wind stress of Hellerman and Rosenstein²³ (henceforth H&R). The surface boundary condition for temperature and salinity is of the relaxation type²⁴, with a relaxation time of 10 days. At the southern boundary, temperature and salinity are relaxed to their climatological values. It is integrated for four years and model fields during the fourth year are used for the discussion below.

Table 1. Vertical levels in the model

Level	Thickness (m)	Depth to the grid point (m)
1	10.0	5.0
2	10.0	15.0
3	10.0	25.0
4	10.0	35.0
5	10.2	45.1
6	10.9	55.7
7	13.5	67.9
8	21.4	85.3
9	42.5	117.3
10	90.7	183.9
11	184.1	321.3
12	336.6	581.3
13	542.7	1021.3
14	765.5	1675.4
15	941.8	2529.1

The geometry of the model is unrealistic with a closed southern boundary, no Indonesian throughflow, closed Malacca strait, lack of island chains and smooth bottom topography. There is no evidence that effects arising from 20°S influence near-surface circulation in the Bay. Similarly, the closing of the Indonesian passage is unlikely to affect the Bay of Bengal circulation because the Indo-Pacific throughflow is found to affect the circulation only to the south of the equator¹³. However, consequences of closing the Malacca Strait and lack of island chains in the model are not known. A deficiency of the model is the lack of river discharge, though it is partly accounted for by the surface boundary condition on salinity. Since the present study is the first attempt to study the Bay using an OGCM we decided to defer exploring the role of river discharge to the future.

3. The annual cycle

During May to September the southeast trades in the south Indian Ocean cross the equator near the African coast and turn southwesterly. In the Bay of Bengal and Arabian Sea the southwesterlies strengthen during June, reach their peak during July–August, start decaying during September, and vanish by October (Figure 1). During November–February northeasterly winds prevail north of the equator, turning northwesterly in the south. These winds reach their peak during December. In the Bay these winds die by the end of February (Figure 1), whereas in the Arabian Sea they persist till March. In general, the winds during November–February are much weaker than the summer monsoon winds.

Winds in the equatorial (5°S–5°N) Indian Ocean (EIO), east of 55°E, are relatively calm throughout the year except during the transition between the monsoons, April–May and October–November, when strong west-lies occur²⁵. Due to these episodes, the annual cycle of the winds in the EIO has a significant semi-annual component. In contrast, the periodicity of winds in the Bay of Bengal is predominantly annual.

In response to the winds, circulation in the Bay exhibits a seasonal cycle both in surface currents and in deeper flow. The ship-drift climatology¹¹ provides a comprehensive view of the seasonal cycle of the surface currents in the Bay of Bengal. We first examine how well the model performs in simulating the upper layer circulation by comparing with ship-drifts.

Comparison with ship-drifts

During February–April ship-drifts in the Bay show (Figure 2a, b) the presence of an anticyclonic (clockwise) gyre with a poleward East India Coastal Current (EICC). To the south of the gyre, approximately along 6°N, a westward current called the North Equato-

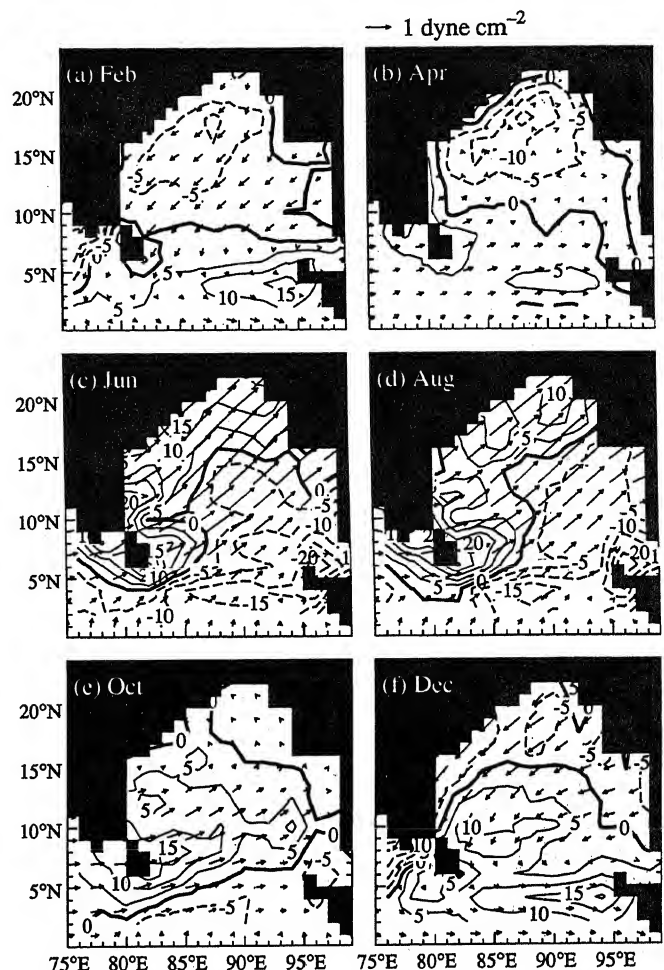

Figure 1. Bi-monthly maps of winds over the Bay of Bengal (H & R). Vectors represent wind stress. Contours represent wind stress curl; thick, dashed and continuous contours represent zero, negative and positive curl respectively. Contour interval is 5 dynes cm⁻³.

rial Current²⁶ (NEC) is present. Piecing together hydrographic data and climatologies^{11,22} Shetye *et al.*⁷ inferred that the poleward EICC in the Bay of Bengal²⁷ during February–May is a part of a seasonal anticyclonic gyre enveloping the entire Bay. The anticyclonic gyre, the EICC and the NEC are reproduced well by the model. The initial formation of the anticyclonic gyre in the model takes place in the northern Bay during January. The EICC forms by February (Figure 2a) and is fully developed by March. During February, the northern part of the EICC is fed by a northwestward flow in the central Bay and the westward North Equatorial Current feeds into the southern part. The model EICC and the anticyclonic gyre are present up to level 10 (about 200 m). Typical speeds are in the range 15–30 cm s⁻¹. During February and March there is a northwestward flow in the southwestern Bay and during April a slow southward drift exists in the rest of the open Bay

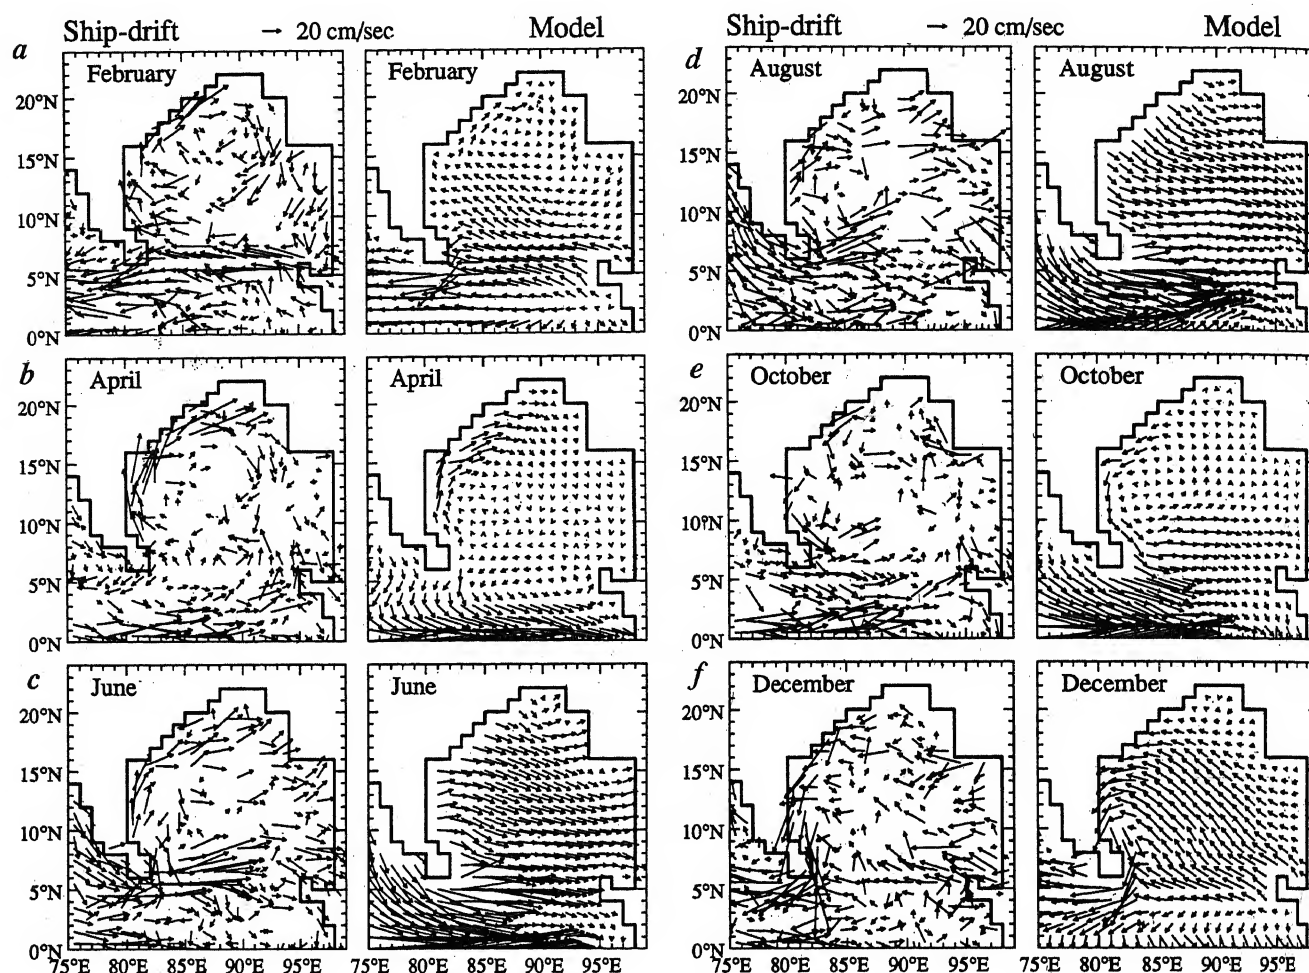

Figure 2. Comparison of the model currents at level 1 (5 m) with ship-drifts. Left panel shows ship-drifts and right panel shows model currents. Five day outputs from the model are averaged to construct monthly mean model currents. To project dominant currents a ship-drift vector was plotted only when the magnitude exceeded 5 cm s^{-1} and when there were more than 5 observations in a 1° box.

(Figure 2 b). The simulated open ocean flow is weaker than the ship-drifts. The ship-drifts suggest a northeastward flow in the southeastern Bay. This flow is very weak in the model. Further, the ship-drifts between 0 and 3°N are eastward, whereas the model flow is towards the southeast.

The ship drifts show that by May the anticyclonic gyre begins to break up and is no longer seen by June (Figure 2 c). A poleward coastal current is seen along the east coast of India during May–June but it cannot be associated with a gyre like in March–April. In the open Bay, in the north, large eastward ship drifts are observed during June–August (Figure 2 c, d). These are probably due to Ekman drift, i.e. directly wind-driven shallow currents, flowing at an angle to the right of the wind in the northern hemisphere. In the model also, an eastward flow is seen in the open Bay during this period. However, the model currents at the first three model levels (5, 15 and 25 m) appear to be dominated by Ekman

flow²⁸, and hence do not compare well with observations. The model Ekman flow is too strong and makes too large an angle with the wind direction. The model eastward current south of Sri Lanka has shifted southward of the observed location. The prominent northeastward flow into the Bay at the termination of this eastward current is not simulated at all. The current along the east coast of India is also not simulated. Clearly the model needs to be improved for a more realistic simulation of the upper layer currents in this season.

Immediately below the layer dominated by Ekman flow (at 35 m), however, the currents along the east coast of India during May and June are well simulated by the model (Figure 3 a, b). At this level there is also a poleward current along the eastern boundary of the Bay. As summer progresses, this current propagates along the boundary of the basin with the coast to its right; by July it is an equatorward flow off the Orissa

4. Sensitivity to horizontal resolution

Since the fundamental length scale of ocean motions, the Rossby radius of deformation, can be smaller than 1° in the latitude range of the Bay of Bengal, a better horizontal resolution is desirable. But the computational load rises steeply with increase in number of grid points and decrease in time step demanded by the numerical stability requirements. As a compromise we set up the model with a minimum spacing of $1/3^\circ$ in the Bay of Bengal and in the EIO. With a grid spacing of $1/3^\circ$, most energetic small-scale features of the flow, including the equatorially trapped waves (which are crucial to the forcing mechanisms described in next section) can be expected to be well represented²⁹. Horizontal eddy coefficients in this case are $2 \times 10^7 \text{ cm}^2 \text{ s}^{-1}$. To save computer time, the depth averaged flow – ‘the barotropic component’ – is suppressed. Since our interest in this study is limited to the upper layers, where the contribution from the depth averaged velocity is small, this is a reasonable strategy to adopt.

One immediate consequence of increasing spatial resolution to $1/3^\circ$ is that the flow field acquires rich spatial structure with embedded eddy type flow pattern, particularly during February–March and June–September (Figure 4). The northwestward flow in the central Bay splits into two branches (Figure 4a, b). The main branch turns northward to feed the EICC between 14°N and 17°N . A small branch forms a cyclonic eddy offshore of the EICC between 10°N and 13°N . During July two anticlockwise cells are present along the western boundary (Figure 4b); the first is located off the Sri Lankan coast and the second off the southeast coast of India. How realistic is this fine structure? We really do not know, but there are references in the literature to similar, relatively small scale features in the Bay of Bengal circulation. Legeckis²⁷ observed in satellite derived SST that eddies characteristic of western boundary currents are present in the Bay of Bengal as well. Babu *et al.*³⁰ documented a subsurface cyclonic eddy along the western boundary during summer monsoon. The flow field along the western boundary during the summer monsoon consists of several cells in the observations of Shetye *et al.*⁴. It is hoped that the present fine-resolution model results would serve as a guideline to plan future field experiments in this direction. Since the wind stress used to force the model does not have the small spatial scales seen in Figure 4a, c, it is suggested that these small-scale structures in the flow field are born from ocean dynamics. This needs to be confirmed through further study.

5. Forcing mechanisms

Modelling studies during the last few years^{12–16} have shown that the main features of the annual cycle of cir-

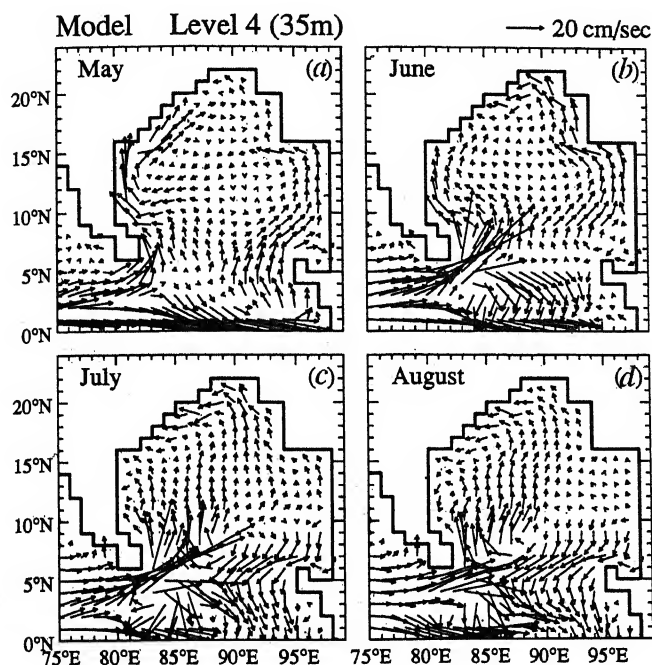

Figure 3. Model currents at level 4 (35 m) during (a) May, (b) June, (c) July, and (d) August.

coast. On the other hand, the poleward current along the east coast of India retreats and disappears by July. The flow field inferred from hydrographic observations along the western boundary of the Bay⁴ supports the model simulation. There are no observations in the eastern part of the Bay to confirm the presence of the poleward current predicted by the model. The model northward flow in the open Bay in July at this level is consistent with observations⁹.

Both model currents and ship-drifts suggest a cyclonic gyre during October–November. This gyre breaks up and a northwestward flow develops in the open Bay during November. Hydrographic data⁸ during December also suggests a similar feature. The formation of a southward coastal current off the east coast of India takes place in the model during October (Figure 2e), after the withdrawal of southwesterly winds. This southward coastal current is present till January.

In summary, we note that the overall pattern of surface currents in the model is consistent with ship-drifts. However, there are differences near the western and southern parts of the Bay during May–September, when the winds are strongest. Both the model level-1 currents and the observed surface circulation are best organized during March–April, when an anticyclonic gyre with a poleward EICC is present. There is also a period of organized cyclonic flow with an equatorward EICC, during October–November.

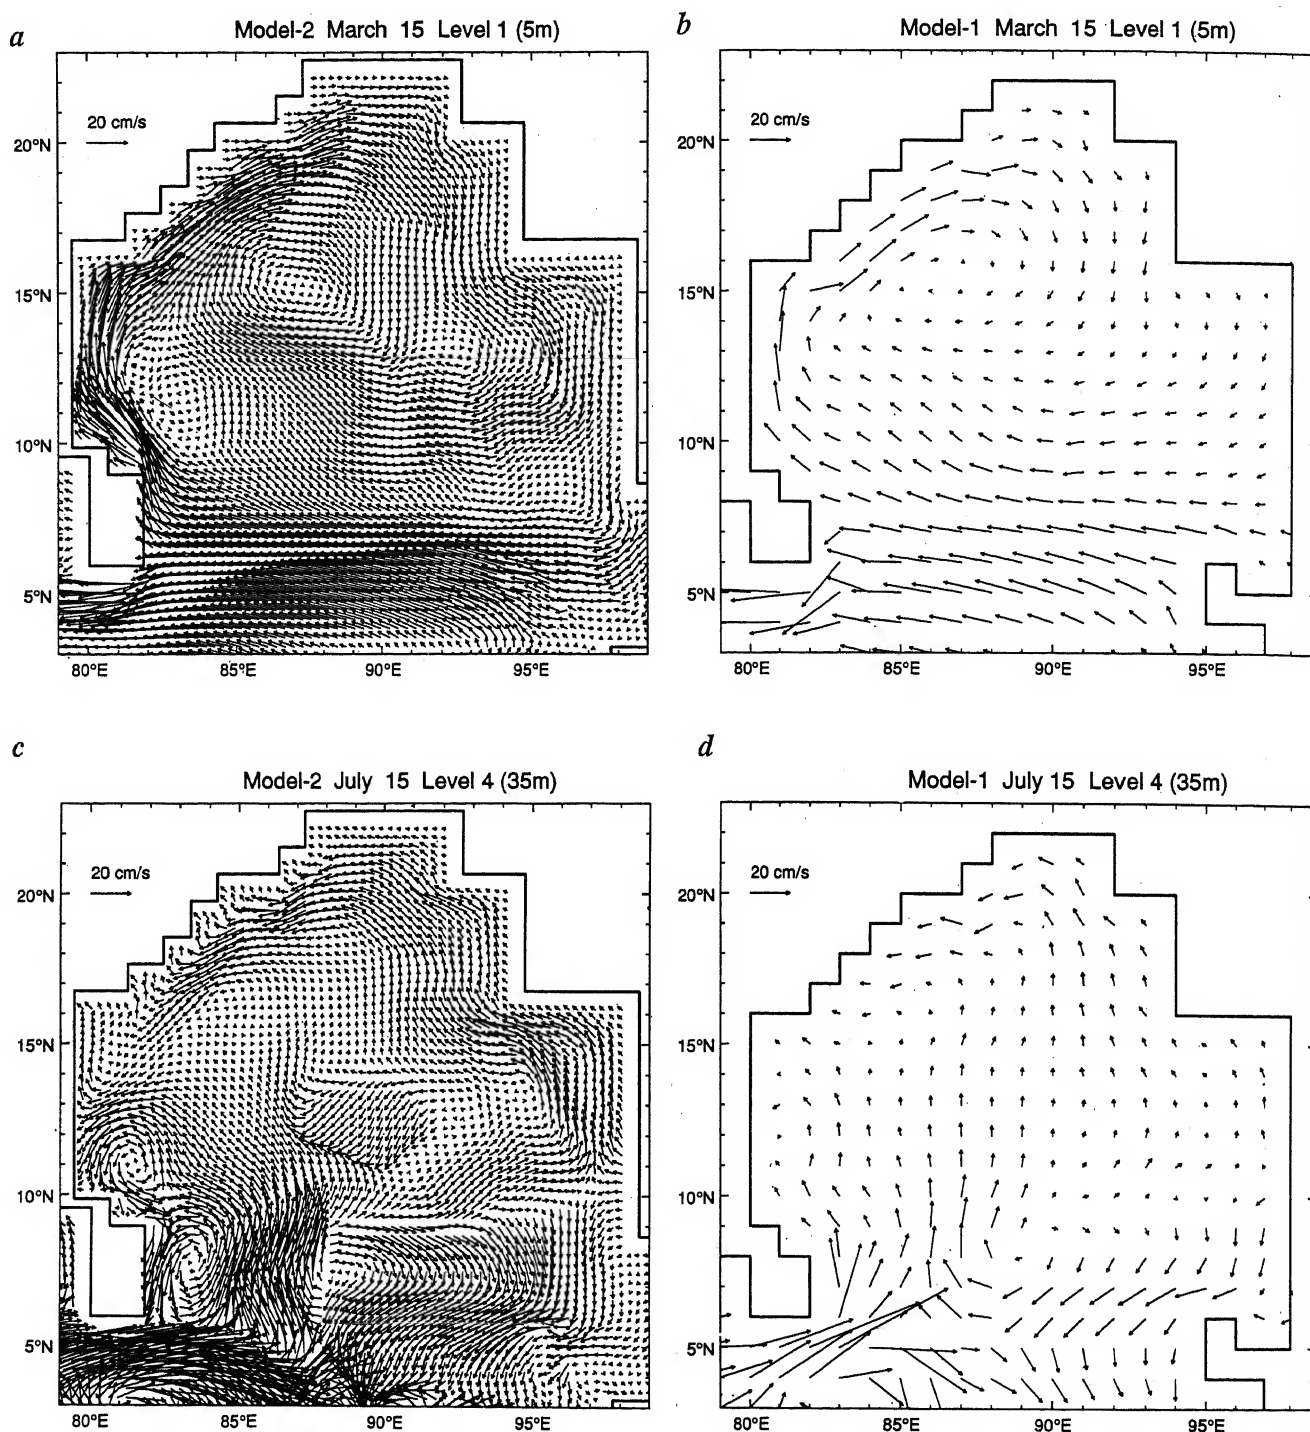

Figure 4. *a*, Currents during March at the first model level (5 m) from the model with a horizontal grid of $1/3^\circ$ in the Bay of Bengal and in the EIO; *b*, Currents during March at the first model level (5 m) from the model with a horizontal grid spacing of 1° over the entire model domain; *c*, Currents during July at the fourth model level (35 m) from the model with a horizontal grid spacing of $1/3^\circ$ in the Bay of Bengal and in the EIO; *d*, Currents during July at the fourth model level (35 m) from the model with a horizontal grid spacing of 1° over the entire model domain.

ulation in the upper Bay can be understood in terms of coastal Kelvin waves along the periphery of the Bay and westward-propagating Rossby waves. The mechanisms that have been identified as generating the Kelvin waves

are alongshore winds in the Bay¹³ and equatorial processes^{12,14}. Rossby waves are generated in the Bay either by Kelvin waves moving along the eastern boundary of the Bay or by the vorticity of the winds (wind stress

curl) over the Bay. We thus have three mechanisms – longshore winds, wind stress curl and equatorial processes – that determine the annual cycle of circulation in the Bay.

In this section we report results of numerical experiments conducted to assess the relative roles of these forcing mechanisms. The model described in section 4 was used for these experiments. In the first experiment winds everywhere except the Bay were switched off; the winds over the Bay being averaged in space to eliminate wind stress curl. The purpose of this experiment was to examine what aspects of the circulation in the Bay can be reproduced with spatially uniform, but seasonally varying winds. In the second experiment, winds were again switched off everywhere except the Bay; the wind stress over the Bay, however, was taken from the monthly mean wind stress climatology²³. In the third experiment winds everywhere were from climatology. The difference between the velocity field in the third and second experiments allows us to identify the contribution to the Bay from elsewhere in the Indian Ocean, primarily from the equatorial belt.

Circulation in the Bay due to curl-free winds over the Bay

Convergence (divergence) in the upper ocean due to wind stress arising from a wind field that possesses curl, induces Ekman pumping (suction) in the deep ocean. Wind stress in the presence of the β -effect (variation of the coriolis parameter with latitude) also gives rise to Ekman pumping (suction)³¹. The major contribution to the Ekman pumping (suction) comes from the curl of the wind stress, the latter mechanism being significant mainly near the equator. We have constructed a simplified wind field over the Bay (Figure 5) by averaging in space the amplitudes of the annual and semi-annual harmonics of the climatological²³ wind stress. The annual and semi-annual harmonics were calculated using a least-square fit to monthly-mean wind stress²³.

The wind stress shown in Figure 5 was applied only over the region north of 9°N. South of this latitude the stress was decreased linearly to zero at 5°N. This tapering of wind stress introduces curl in the region 5–9°N. In the discussion below, we examine only the region north of 10°N. Shown in Figure 6 are velocities at 35 m, i.e. at a depth where Ekman velocity does not dominate the flow field.

The wind-field shown in Figure 5 essentially consists of two regimes. The first, made of southwesterly winds is stronger and starts building up during April. In response, a Kelvin wave pulse is generated along the eastern boundary (Figure 6 b). As the winds strengthen, the velocity field associated with the Kelvin wave strengthens. Kelvin waves can radiate Rossby waves offshore.

Figure 5. Annual cycle of zonal (full line) and meridional components (dashed line) of simplified spatially uniform wind stress.

By June (Figure 6 c), the Rossby wave radiated by the Kelvin wave can be seen as far west as 90°E. In addition, a patch of westward velocity can be seen west of about 87°E between 12 and 15°N. For the wind field used here, the only mechanism that can give rise to such a patch is Ekman suction due to β -effect. The upwelling favourable winds along the western boundary drive a poleward EICC there. This current weakens during July, although the wind stress peaks then. This is caused by the arrival of the downwelling Kelvin wave from the eastern boundary (Figure 6 c). The downwelling Kelvin wave is modified by the local upwelling favourable winds. In the northern part of the coast the downwelling wave dominates; as one moves southward, however, local forcing overwhelms it.

The southwesterly winds weaken during August. Seeking equilibrium with weakening winds, the velocity associated with the Kelvin wave at the eastern boundary falls to zero, and the flow then turns southward (Figure 6 d, e). This starts an upwelling phase of the Kelvin wave along the eastern boundary of the Bay. The southwesterlies withdraw during September and October, and the Kelvin wave along the eastern boundary has southward velocity along the entire coast (Figure 6 e).

During August the northward velocity associated with the Rossby wave radiated by the downwelling Kelvin wave (April–July) covers the entire Bay (Figure 6 d). As the velocity associated with the Kelvin wave at the eastern boundary turns southward, the velocity associated with the westward moving Rossby wave also turns southward (Figure 6 e). A region of weak flow separates

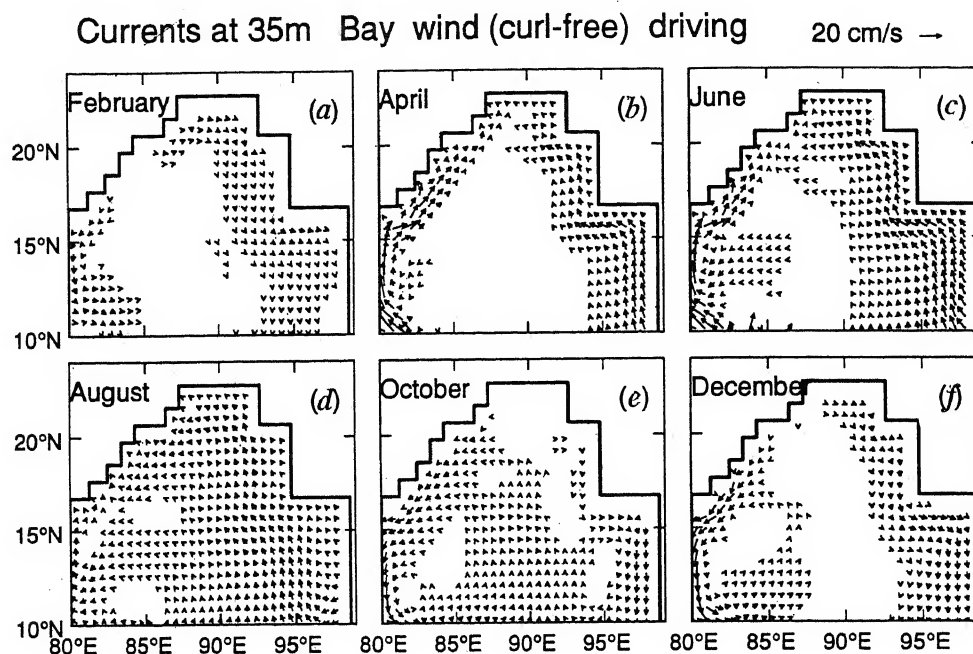

Figure 6. Currents at 35 m for the run with wind stress shown in Figure 5. The wind stress was applied only over the Bay of Bengal. A current vector was plotted only when the magnitude exceeded 2 cm s^{-1} .

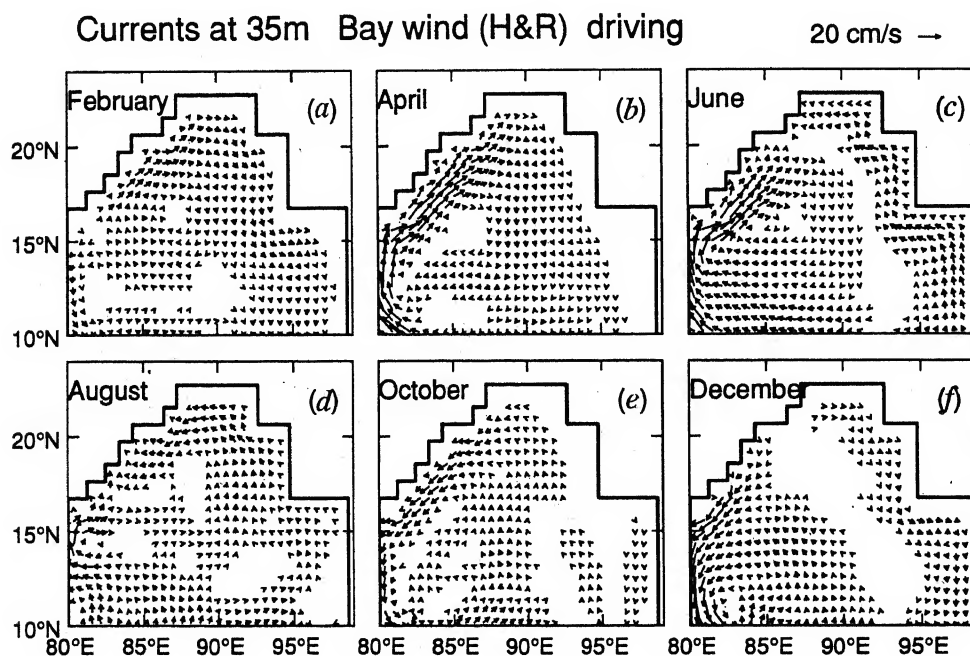

Figure 7. Same as Figure 6 but for the run with H & R winds applied only over the Bay.

(Figure 6 *e*) the regions of northward and southward velocities; the latter is seen only close to the coast.

The decrease of southwesterly winds also affects the flow along the western boundary: the locally driven

poleward current weakens (Figure 6 *d*). As the southwesterly winds collapse, adjustment to the new wind field leads to the southward current (Figure 6 *e*), a process highlighted by MKM. Another mechanism that adds

to the southward current is the reflection of the leading edge of the Rossby wave. Upon reflection this wave produces a narrow band of southward velocity. This reflected Rossby wave has a smaller wavelength.

The northeasterly winds are most intense during November–December. In response, an upwelling Kelvin wave forms along the eastern boundary. It is weaker than the downwelling Kelvin wave during April–July (compare Figure 6f with Figure 6c) because the wind stress is weaker.

During November, the Rossby wave radiated by the downwelling Kelvin wave of the summer monsoon is still present in the central Bay. This is seen as the westward migration of a patch with northward velocity, its reflection from the western boundary and the resulting southward EICC. In the eastern half of the Bay the Rossby wave pulse radiated by the upwelling Kelvin wave is present (Figure 6f). However, there is no indication of this Rossby wave crossing the Bay to have an impact on the western boundary. This is because the Rossby wave packet is weak and gets dissipated by the time it reaches the central Bay. Along the western boundary the northeasterly winds contribute to an equatorward flow during November–January (Figure 6f). By March the winds collapse; adjustment to the new winds leads to the formation of the poleward EICC.

Comparing Figures 6 and 2 we see that the overall pattern of near surface circulation has been reproduced well in this run with simplified winds. The process that was most active in this run was the generation of Kelvin wave pulses along the eastern boundary of the Bay. An important difference between this run and the one discussed in section 3 is that the circulation is weak in the former, implying that other mechanisms must be present to enhance the circulation.

Circulation due to winds over the Bay

In this experiment the model was forced by the annual cycle of H & R wind stress only over the Bay of Bengal. The purpose of this experiment was to examine the circulation in the Bay in the absence of equatorial wind forcing. An important difference between the run in the previous sub-section and the present run is that now Ekman suction from curl of wind stress is present. The simulated currents at 35 m are shown in Figure 7. Below we discuss the changes seen in this figure from the circulation described in section 5.1

During March–April, the main difference from the previous run is that there is a well developed anticyclonic gyre with a poleward EICC (Figure 7b). Because of the gyre, the velocity field in the open Bay is stronger (compare Figure 6b with Figure 7b). The primary cause of the difference between these figures is the contribution from wind stress curl. The currents along the eastern Bay are prominent in the case of curl-free driving due to the alongshore winds.

(a) Ship-drift U-component 2°S–2°N

(b) Model U-component Equator

Figure 8. Time longitude sections of zonal velocity (i) in the equatorial region (averaged between 2°S and 2°N) from the ship-drifts and (ii) along the equator from the model. Thick line represents zero contour and dotted contours represent westward flow. Eastward velocity greater than 60 cm s^{-1} is shaded to show the equatorial jets.

During November–January, the southward EICC is stronger in the present run (compare Figure 6f with Figure 7f). The principal cause behind this change is a patch of wind stress curl which forms over the region off Sri Lanka during October. The northward flow in the open Bay seen in the earlier experiment was the result of the Rossby wave radiated from the eastern boundary. Now, in the presence of wind stress curl, the contribution to the velocity field from that Rossby wave is increased due to the contribution from wind stress curl. The net result is a strengthening of the equatorward EICC.

Thus, the presence of wind stress curl strengthens the EICC by generating two gyres: an anticyclonic gyre during March–May in the Bay and a cyclonic gyre off the coast of southern India during the winter.

Circulation due to winds over the equatorial Indian Ocean

The source of all equatorial effects in the Bay is the equatorial Kelvin wave. To ensure that equatorial effects are properly accounted for, it is necessary that equatorial circulation be correctly simulated by the model.

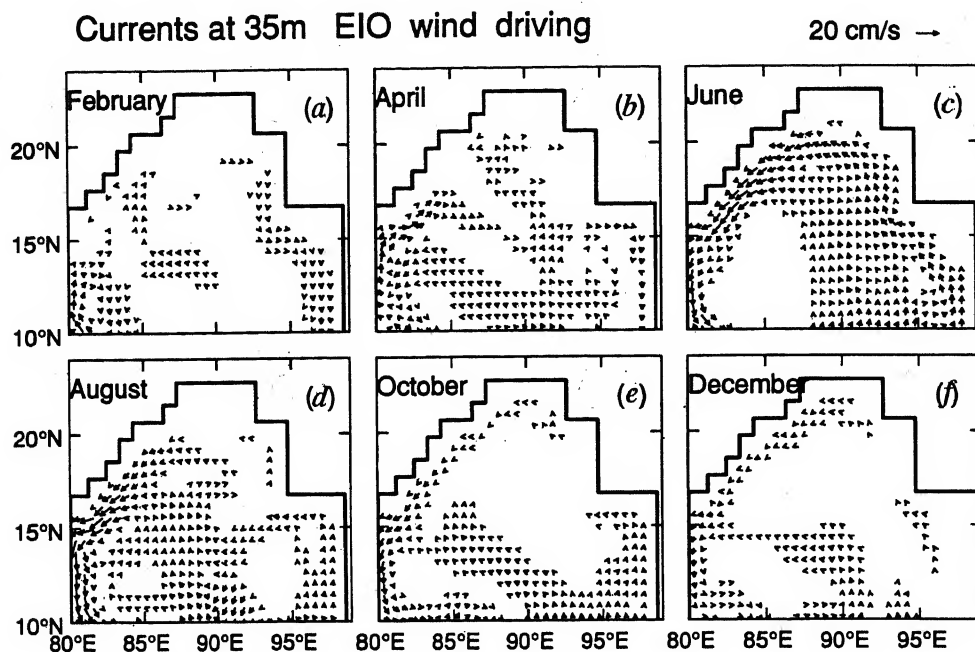

Figure 9. Currents at 35 m due to equatorial processes. This is calculated by subtracting the model result with winds (H & R) only over the Bay from the model result with winds (H & R) over the entire model domain. A current vector was plotted only when the magnitude exceeded 2 cm s^{-1} .

This can be seen in Figure 8 *a, b*, which shows the zonal component of monthly mean ship-drifts¹¹ and zonal velocity from the model. There is good resemblance between Figure 8 *a* and *b*, implying that equatorial circulation has been reasonably well reproduced. In particular, during April–May and October–November strong eastward jets similar to those first noted by Wyrtki³² occur in the model. Note that MKM were unable to simulate the fall jet.

To study the impact of equatorial processes on the Bay of Bengal circulation, the velocity field in the run with winds only over the Bay was subtracted from that with winds over the entire model domain. The resulting velocity field is shown in Figure 9.

The velocity field in the Bay associated with equatorial forcing is weak (Figure 9). The most significant result of this driving is an equatorward current during the summer monsoon. This current is opposite in direction to those seen in the earlier two experiments (compare Figure 9 *c, d* with Figure 7 *c, d* and Figure 6 *c, d*).

In brief, the numerical experiments carried out here show that we can understand the annual cycle of circulation in the Bay in terms of the following: (i) Two Kelvin wave pulses generated by alongshore winds in the coastal region of the Bay, mainly its eastern boundary. (ii) Circulation set up by wind stress curl over the Bay; primarily an anticyclonic gyre during March–May and a cyclonic gyre in the southwestern Bay during

October–December. (iii) A weak circulation set up by equatorial forcing, whose main effect is to reduce the strength of the poleward current during the summer monsoon.

6. Conclusions

The results of numerical experiments discussed above show the usefulness of the OGCM in simulating and understanding the upper-layer circulation in the Bay of Bengal. The model reproduces most of the features seen in the available data sets. The results of the numerical experiments allow us to construct the following hierarchy of processes dominating the circulation in the Bay:

- i) *Coastal Kelvin wave pulses generated along the boundary region, primarily the eastern boundary*

The more important of the two pulses is the downwelling pulse generated with the onset of the south-westerly winds. Its impact on the coastal current is most important in the north during the summer monsoon. The second pulse, an upwelling event, occurs during the winter monsoon and it generates a poleward EICC during March. Both these pulses contribute towards circulation in the Bay by radiating Rossby waves. However, it is necessary to invoke

other mechanisms to explain all the features of circulation.

ii) *Rossby waves generated by Ekman suction over the Bay*

The main function of this mechanism is to strengthen the EICC by generating an anticyclonic gyre during March–May and a cyclonic gyre during the winter monsoon.

iii) *Effects derived from the equatorial region*

The most significant effect of this forcing is an equatorward current off the east coast of India during the summer monsoon. This current is opposite to that driven by the winds over the Bay.

It is clear that more modelling studies are required, for instance, to improve the simulation of the currents during the summer monsoon. Above all, a well planned observational programme is a must for further progress in understanding the dynamics and thermodynamics of the Bay of Bengal and its coupling with the monsoon. Although theoretical studies suggest that low-frequency Rossby and Kelvin waves are crucial to the circulation, their presence has not been established in the field. The impact of freshwater driving and the nature of space-time variation of the stratification of the Bay also needs to be elucidated with the help of more observations. None of the model studies so far have taken into account the freshwater input into the Bay explicitly. In future modelling studies, the important problem of understanding the role of buoyancy driving in the circulation of the Bay will be addressed.

Comparison of three different tests for detection of cucumber mosaic cucumovirus in banana (*Musa paradisiaca*)

G. Kiranmai, P. Sreenivasulu and M. V. Nayudu

Department of Virology, S. V. University, Tirupati 517 502, India

Direct ELISAs like double antibody sandwich (DAS)-ELISA, simplified rapid direct antigen coating (SRDAC)-ELISA and indirect form of DAC-ELISA for detection of cucumber mosaic cucumovirus (CMV) causing infectious chlorosis of banana in leaf extracts and pseudostem sap exudates and purified virus diluted with antigen buffer or healthy banana leaf sap were compared. The sensitivity levels of three ELISA tests were similar and the virus was detected up to 10^{-7} dilution with leaf extract, 1 μ l/well with sap exudate, 20 ng/well with purified CMV and 100 ng/well with purified virus diluted with healthy banana leaf extract. Of three forms of ELISA compared, DAC-ELISA was further evaluated with detection of infectious virus by local lesion bioassay on cowpea (*Vigna unguiculata*) and by double stranded RNA (dsRNA) analysis. The banana leaf and pseudostem sap exudate samples that were positive in DAC-ELISA were also positive by other two tests. Collection of pseudostem sap exudates by pin pricking from test plants and detection of virus by DAC-ELISA in them appears ideal for large-scale testing of banana plants.

THE banana (*Musa paradisiaca*) is one of the world's most important tropical fruit crops. It is grown in all types of tropical agricultural systems¹. Bananas are propagated vegetatively through suckers. Viruses as systemic pathogens are readily disseminated in vegetative propagation material and usually cause serious problems in crops propagated in this way.

The causal viruses of bunchy top (banana bunchy top virus-BBTV), infectious chlorosis (cucumber mosaic cucumovirus-CMV), bract mosaic (banana bract mosaic potyvirus-BBMV), streak (banana streak badnavirus-BSV) and tobacco mosaic virus¹⁻⁴ diseases of banana are vertically transmitted through planting suckers.

Four viruses are known to naturally infect banana in East and West Godavari districts of Andhra Pradesh state in India (personal communication, Krishna Prasadji, Banana Research Station, APAU, Kovvur). The field identification of diseases caused by CMV, BBMV and BSV based on the symptoms in banana is difficult as they induce similar symptoms (chlorotic streaks) at certain stages of disease development.

The infectious chlorosis disease caused by CMV has been reported from India, Australia, Greece and Morocco⁵⁻¹⁴. Recently, a virus causing severe chloro-

sis/mosaic disease of banana in Uttar Pradesh, India was identified as a strain of CMV using slot-blot hybridization with nucleic acid probe of CMV-P genome¹⁵. Currently, the recommended strategy for control of CMV in banana is to identify virus-infected plants, remove the diseased plants and replant with virus-free banana plants¹. In order for this approach to be successful, it is necessary to have sensitive, rapid and reliable indexing tests for the detection of CMV from banana plants. Hansen and Wick¹⁶ reviewed the various biological, immunological and biochemical tests used for detection and identification of plant viruses. Of these, ELISA-based tests have been widely used because of their simplicity, economy and adaptability for large-scale testing of suspected plant samples.

In view of potential importance of CMV in banana¹⁷, we evaluated three ELISA procedures and compared one of them with bioassay and double stranded (ds) RNA analysis for detection of CMV in banana leaf extracts and pseudostem sap exudates collected by pin pricking.

CMV causing infectious chlorosis in banana plants growing under natural conditions in Andhra Pradesh served as the source of primary inoculum. The virus culture was initially established on cowpea and single lesion isolate was subsequently propagated on tobacco by sap inoculation and on banana by injecting the purified virus¹⁸. Virus-free banana plants were propagated by transplanting virus-free suckers indexed by DAC-ELISA. The virus was purified from virus-infected tobacco leaves harvested twenty days after sap inoculation essentially by following the procedure of Walkey¹⁹. The concentration of purified virus was determined by considering 5 OD units = 1 mg (ref. 20).

Polyclonal antiserum prepared previously to CMV-banana isolate was used in this study¹⁸. Immunoglobulins (IgG) from crude CMV-banana antiserum for direct ELISA procedures were purified by sodium sulphate precipitation followed by dialysis as described by Rajeswari *et al.*²¹. Alkaline phosphatase (Sigma) was conjugated to CMV IgG and goat antirabbit antibodies (Gibco, USA) by one step glutaraldehyde method²².

The composition of buffers and plate-washing procedures were similar to those of Clark and Adams²². The volumes of reactants added to each step unless otherwise stated were 200 μ l/well. All ELISA incubation periods prior to substrate addition were 90 min at 37°C in a humid box. ELISA plates with flat bottom wells (Laxbro, Pune) were used in all procedures.

The antigen samples for simultaneous testing used were banana pseudostem sap exudate collected separately from healthy and CMV-infected banana by pin pricking the pseudostem (10, 20, 50, 100 μ l/ml), banana leaf sap (10^{-1} – 10^{-8} dilution), purified CMV-banana (0.1–2.0 μ g/ml). For direct antigen coating procedures (DAC, SRDAC) the antigens were extracted (1 g/9 ml buffer) and diluted in 0.05 M carbonate buffer, pH 9.6

Table 1. Detection of CMV causing infectious chlorosis of banana by different forms of ELISA

Type of antigen	Antigen concentration ^a	Direct form		Indirect form

^aAntigens (Sap, purified virus and pseudostem sap exudate) diluted in PBS-TO containing DIECA for DAS-ELISA and in carbonate buffer containing DIECA for DAC and SRDAC-ELISA; ^b,^cALP labelled CMV-B antibodies used at 1:500; ^dALP labelled goat antirabbit antibodies used at 1:1000;

^eValues are an average absorbance A₄₀₅ of three wells recorded after 90 min of adding substrate.

containing 0.01 M DIECA. Whereas for DAS-ELISA they were extracted and diluted in PBS-TO containing 0.01 M DIECA. The antigen dilutions in each procedure were replicated in three wells in each of the experiments.

Antiserum and enzyme-conjugated IgG were diluted in PBS-TO. *p*-Nitrophenyl phosphate (PNP) prepared just before use at 0.5 mg/ml diethanolamine buffer, pH 9.8 was used as a substrate, NaOH (3M) at 50 µl/well used to terminate the reactions.

DAS-ELISA described by Clark and Barjoseph²³ was followed. CMV-banana IgG at 1:500 in carbonate buffer, pH 9.6 was added to the plates as trapping antibodies. Antigen samples prepared in PBS-TO were added after washing the plate, followed by alkaline phosphatase labelled CMV-IgG at 1:500 dilution. After washing, the substrate was added and incubated at room temperature for 90 min. Absorbance readings (A₄₀₅) were recorded with Bio-Tek Ceres 900 ELISA reader over buffer controls. Readings twice those of healthy were considered as positive.

The procedure for SRDAC-ELISA was similar to DAS, but here the plates were directly coated with antigen samples prepared in carbonate buffer, pH 9.6 (ref. 24). The trapped antigens were detected by alkaline phosphatase labelled CMV-IgG as described above.

For DAC-ELISA, the plates were directly coated with antigen samples prepared in carbonate buffer, pH 9.6 (ref. 25). Crude CMV-banana polyclonal antiserum at 1:500 dilution in PBS-TO was added after washing. Alkaline phosphatase labelled goat antirabbit antibodies at 1:1000 in PBS-TO were added to the plate to detect the antigen-antibody reaction. The plate was incubated with *p*-nitrophenyl phosphate for 90 min at room temperature. The absorbance values were recorded as described under DAS-ELISA.

The virus-infected banana leaf samples from different plants were separately ground (1 g/9 ml) in inoculation buffer (0.01 M KPO₄ buffer, pH 7.2 containing 0.2% 2-mercaptoethanol) and sap inoculated to carborundum powder (600 mesh) dusted *Vigna unguiculata* plants and observed for development of local lesions. Pseudostem

sap exudate was separately collected by pin pricking from different infected plants and diluted with inoculation buffer (500 μ l/ml). This sap was inoculated to abrasive dusted *V. unguiculata* plants.

The dsRNA was isolated from CMV-infected banana leaves and pseudostem sap exudates by lithium chloride fractionation method of Diaz-Ruiz and Kaper²⁶ and analysed by 2% agarose gel electrophoresis²⁷.

The concentrations of crude antiserum, IgG, enzyme-labelled IgG used in the present study were chosen based on preliminary experiments. Further dilutions of these reagents resulted in weak reactions. The virus was detectable at 10^{-7} dilution of banana leaf sap, 5 μ l/ml (1 μ l/well) of pseudostem sap exudate, 100 ng/ml (20 ng/well) of purified CMV-banana and 500 ng/ml (100 ng/ml) of purified CMV-banana diluted with healthy banana leaf sap in all three tests (Table 1). However, the absorbance values were marginally higher in DAC-ELISA when compared to other two tests. Dilutions of the purified virus with healthy banana leaf extract resulted in decreased sensitivity of virus detection by about five times. Among three forms of ELISA, the sensitivity of DAC-ELISA was compared with local lesion bioassay and dsRNA analysis tests for detection of CMV in banana (Table 2). The banana leaf samples and pseudostem sap exudates that were positive by DAC-ELISA were also positive by the other two tests. In the bio-assay test, cowpea plants inoculated with both infected banana leaf extract and pseudostem sap exudate produced necrotic local lesions after three days of sap inoculation [23 to 34 lesions/primary leaf]. The dsRNA extracted from both infected leaf and pseudostem sap exudate was resolved into 3 bands (Figure 1) with Mr of RNA 1–2.56, RNA 2–2.24 and RNA 3– 1.66×10^6 d. No such bands were observed in the corresponding healthy plant samples.

Biological, immunological and molecular techniques are used for diagnosis of CMV-caused diseases¹¹. The choice of these techniques is based on expertise and laboratory facilities available, specificity, sensitivity, cost and time factor. Among serological techniques agargel diffusion and ELISA based ones were used for detection of CMV in various plant samples.

In the present investigation, we evaluated both direct (DAS-ELISA and SRDAC-ELISA) and indirect (DAC-ELISA) forms of ELISA for detection of CMV in banana. Sampling from banana by way of collection of pseudostem sap exudate by pinpricking appears simple and ideal in large-scale testing of banana plants/planting suckers (sometimes without leaves) when compared to collection of leaf samples and preparation of extracts from them.

In the present studies the virus was detectable at 10^{-7} dilution of banana leaf sap, 5 μ l/ml of pseudostem sap exudate and 100 ng/ml of purified CMV-banana in all three ELISA tests. During the extraction of banana

leaves for CMV indexing, samples that oxidize despite the presence of reducing agents can produce false positive reactions in ELISA¹¹. These reactions can be minimized by thorough washing of the mucilaginous antigen samples from the wells of the plate before adding the next reagent.

Eyen though there is no significant difference in the sensitivity levels of virus detection with three tests, the reagents and time required to carry are varied. DAC-ELISA is economic, requires about 5–6 h and is more versatile as the test can be automated and commercialized for application to crops like banana.

In laboratories with minimal facilities, more glasshouse and time (3–4 days) are not the criteria, detection of CMV in banana by bioassay on local lesion hosts like cowpea or green gram (*Phaseolus aureus*) appears suitable routine practice. Further, the other four viruses known to infect banana did not infect these local lesion hosts and thus bioassay is useful for distinguishing CMV from other viruses of banana.

The dsRNA analysis has been used as one of the criteria for identifying the various isolates of CMV in Australia¹². The application of this technique requires more time (2–3 days), expertise and expensive laboratory facilities. Moreover it is suitable for detecting the virus in a small number of samples. The samples that were positive by DAC-ELISA are also positive by the other two tests (Table 2). Finally we conclude that DAC-ELISA is a suitable test for routine application in large-scale testing of banana encountered in plant quarantine, in planting material (suckers) certification programmes and in banana field surveys.

Thin layer problem in geoelectrics

I. B. Ramaprasada Rao, Ram Raj Mathur and S. Srinivas

Centre of Exploration Geophysics, Osmania University, Hyderabad 500 007, India

Inferences in the influence of a thin conductive layer on the controlled source audiofrequency magnetotelluric (CSAMT) Cagniard response as compared to magnetotelluric (MT) soundings are studied. For this purpose, H_r and E_ϕ components are computed due to a horizontal electric dipole (HED) over a layered media without imposing farfield or nearfield conditions for the CSAMT method. The computation is carried out in a cylindrical coordinate system using Hankel transform of Bessel functions of order zero and unity with a 100 point digital filter.

The root mean square (RMS) deviations between the CSAMT response with and without thin conductive layer, in the frequency ranges of 0.125 Hz to 4096 Hz are computed. A similar scheme of computation is implemented for the MT response. This difference is uniformly higher for the CSAMT within the range of parameters investigated and hence the CSAMT method is preferable over the MT method for delineation of the thin intermediate conductive layer. Conversely, if a lesser influence of the thin conductive layer is desired, MT soundings are preferred over CSAMT studies.

RESEARCH COMMUNICATIONS

THE influence of a thin conductive layer has been studied in electromagnetic prospecting by several authors¹⁻¹⁵. Molochnov¹⁶ studied the influence of a thin conducting layer on the field components of a vertical magnetic dipole (VMD) source in terms of tabulated functions so that the maximum effect can be computed for any chosen frequency. The present study is aimed at assessing the influence of thin conductive layer on CSAMT Cagniard response as compared to MT. This study acquires added significance in view of the presence of conductive thin layers (red bole) and intra- and infratrappean sedimentary sequences in the vast Deccan flood basalt region which is coming into sharp focus for two reasons, namely, neotectonic activity and energy resource potential of the lithounits below the Deccan trap covered terrain.

The components of the electromagnetic field on the surface of a multilayered earth for a horizontal electric dipole (HED) are available in literature¹⁷. Over a multilayered earth for far field conditions ($|k| \gg 1$ where k is the wave number given by $k = \sqrt{j\omega\mu}$), the apparent resistivity can be obtained as

$$\rho_a = \frac{1}{\omega\mu} |Z_n|^2, \quad (1)$$

where Z_n is the ratio of electric and magnetic field components.

The apparent resistivity for the MT method over a multilayered earth¹⁸ can be obtained through equation (1), where the impedance Z_n is given by

$$Z_n = \frac{\omega\mu}{k_1} \cot h \left\{ -ik_1 h_1 + \cot h^{-1} \left[\frac{k_1}{k_2} \cot h \left(-ik_2 h_2 + \cot h^{-1} \left\{ \frac{k_2}{k_3} \cot h \left(-ik_3 h_3 + \dots + \cot h^{-1} \left(\frac{k_{n-2}}{k_{n-1}} \cot h \left(-ik_{n-1} h_{n-1} + \cot h^{-1} \frac{k_{n-1}}{k_n} \right) \right) \right\} \right) \right] \right] \right\}. \quad (2)$$

Thus, in the far field conditions, the CSAMT apparent resistivity fully coincides with the MT Cagniard resistivity. However, a marked difference exists when the condition of $|k| \gg 1$ is not valid¹⁹⁻²¹.

We computed two categories of Cagniard CSAMT responses as a function of frequency using the corresponding equations (expressions 2.191, 2.209 and 2.210) (ref. 17) for a multilayered earth in order to investigate the effect of a thin conductive layer on the CSAMT response. Category I corresponds to two-layer geoelectric model for different ρ_2/ρ_1 and r/h_1 values, where r is the transmitter receiver separation and ρ_1 , ρ_2 and h_1 are the resistivities of the first and second layers and the thickness of the top layer respectively. Category II corresponds to geoelectric models with a thin layer of constant thickness (1 m and 2 m) and resistivities

Figure 1. Geoelectrical models.

(0.04 ohm m) with varying depth of burial introduced into the two-layer system (chosen in Category I). The details of these models are given in Figure 1. The MT response curves were computed using equations (1) and (2) for the same geoelectrical models.

The scheme of computation developed for this purpose first computes the H_r and E_ϕ components due to a HED source over layered media without imposing either the farfield or the nearfield conditions and then computes the Cagniard resistivities and RMS difference²² between CSAMT response curves with and without the thin layer, in the entire measurement range of frequencies. The electromagnetic field of HED was computed in a cylindrical coordinate system using Hankel transforms of Bessel functions of order zero and unity with a 100 point digital filter²³.

A similar computational scheme implements the procedure for MT response.

Figures 2 and 3 show examples of four pairs of response curves for the CSAMT and MT respectively. The solid curves a, c, e and g in Figure 2 are two layer cases with resistivities $\rho_1 = 1.0$ ohm m and $\rho_2 = 0.66$ ohm m and $h_1 = 2, 5, 10$ and 20 m in this order (category I). The broken curves (b, d, f and h) shown in Figure 2 involve a thin conducting layer of resistivity 0.04 ohm m and thickness 1 m at depths 2, 5, 10 and 20 m in this order (category II). A similar representation has been used for the MT responses in Figure 3.

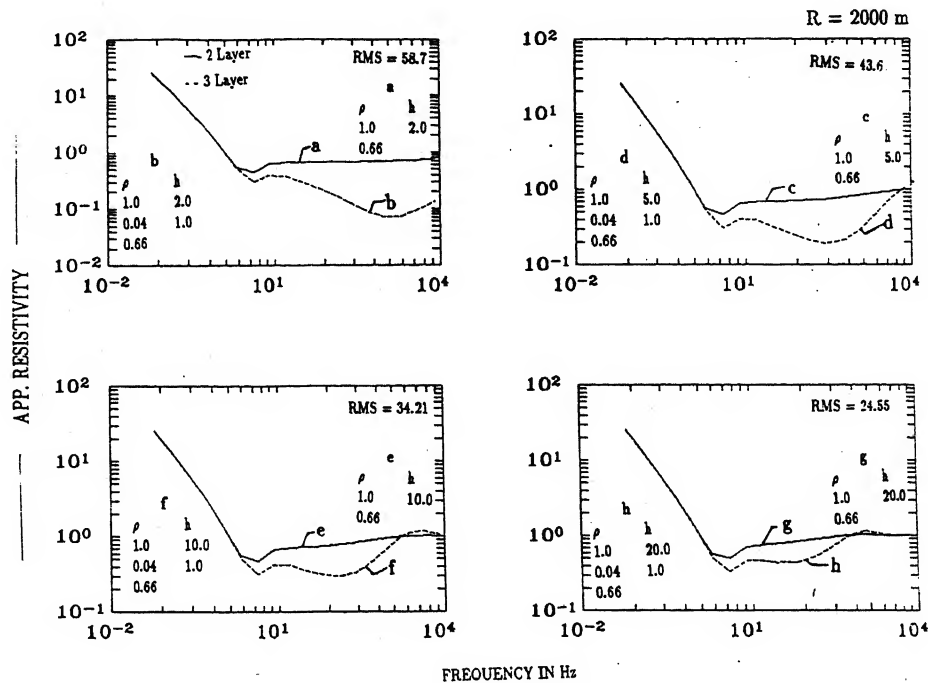

Figure 2. CSAMT response without and with the thin conductive layer.

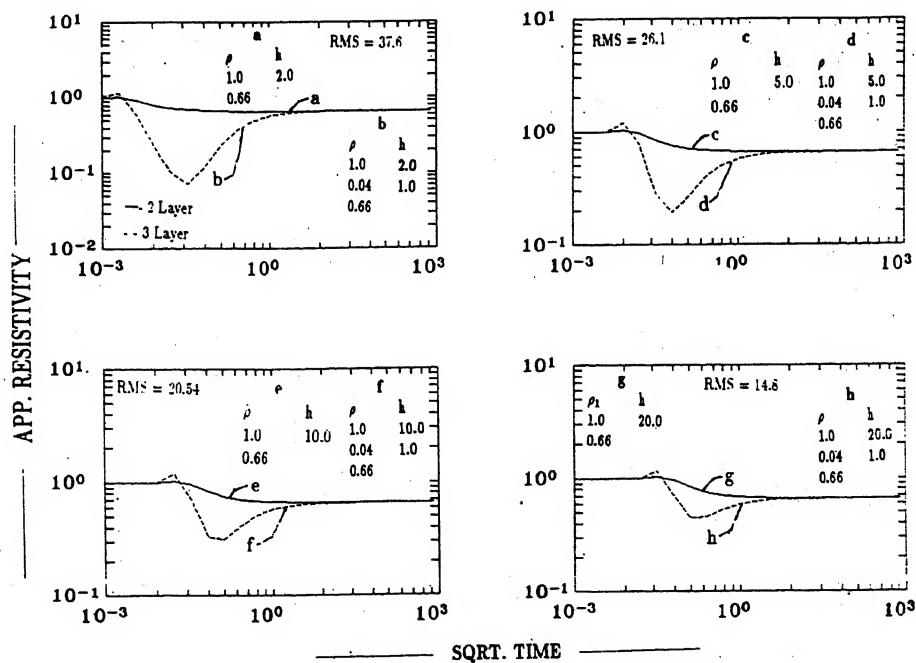

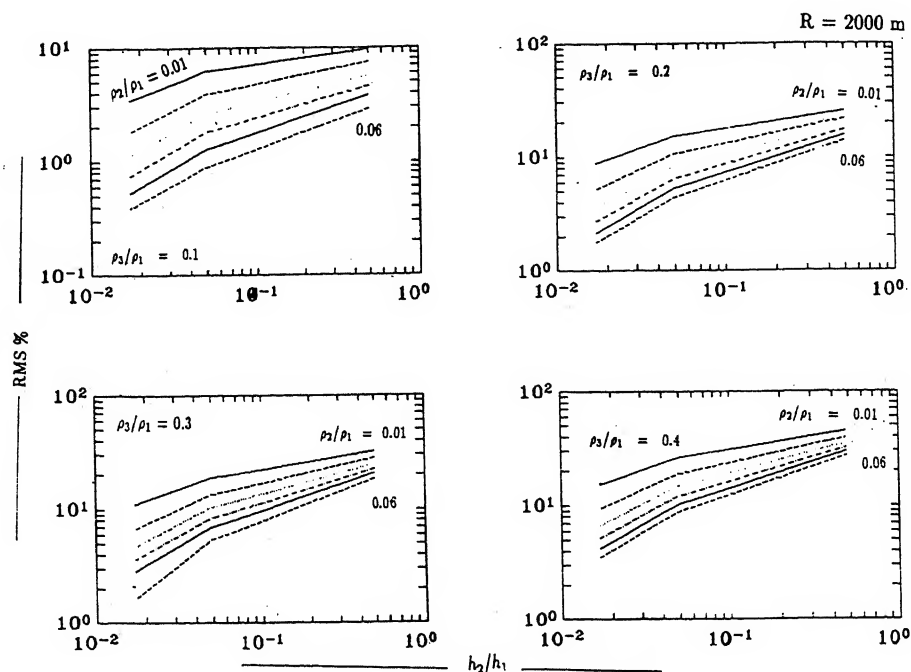

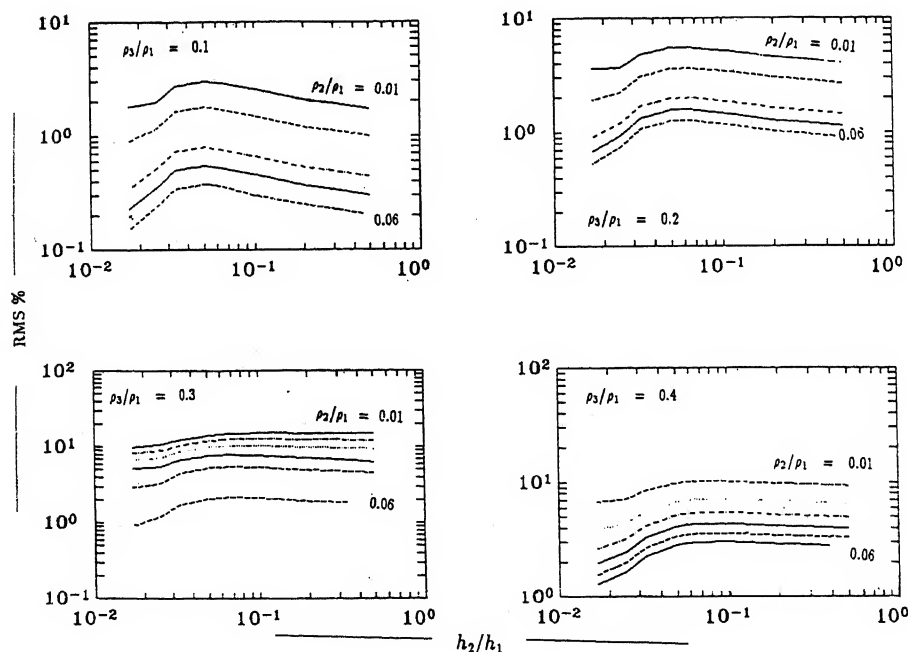

Figure 3. MT response without and with the thin conductive layer.

The normalized non-dimensional presentation allows one to understand the effects for multitude of geoelectric truths from the response functions thus computed.

We can note (from Figure 2), as is expected, that the RMS difference between the CSAMT response with and

without the conducting layer progressively diminishes as the depth to the thin conductive layer increases.

The relationship of RMS difference with h_2/h_1 for various ρ_2/ρ_1 ratios for a particular ρ_3/ρ_1 value in the CSAMT and MT is shown in Figures 4 and 5 respec-

Figure 4. Relationship between h_2/h_1 and RMS error % for CSAMT data.Figure 5. Relationship between h_2/h_1 and RMS error % for MT data.

tively. We thus obtained the combination of h_2/h_1 , ρ_2/ρ_1 and ρ_3/ρ_1 for any chosen RMS value.

Figure 6 shows a comparison of the RMS deviation in percent for different thickness ratios in the CSAMT and MT techniques. The RMS deviation is consistently

higher for the CSAMT technique (compared to MT) within the range of parameters investigated and hence the delineation of the thin conducting layer as a separate entity is better in CSAMT when compared to MT. However, in case lesser influence of the intermediate con-

Figure 6. Comparison of RMS error in CSAMT and MT.

ducting layer is desired, MT soundings are preferable over CSAMT studies. In general, it appears that the influence of a thin conductive layer increases, with an increasing h_2/h_1 for given resistivity contrast in the CSAMT. On the other hand it is interesting to observe that a sort of a 'tuning effect' with respective h_2/h_1 is seen in the MT technique for certain resistivity contrasts, which implies that within a range of h_2/h_1 (0.03 to 0.05 in Figure 6) the influence of thin conductive layer is prominent in the MT technique. However, this tuning effect depends on the resistivity contrast also. For large values of h_2/h_1 , the CSAMT sounding appears to be more suitable than the MT technique, when the study is aimed at detecting the intermediate conductive layer.

Thus, it is desirable to explore the potential of the CSAMT technique for the effective detection of sedimentary units intermediate conductive layers (intratrapeans, redbole vesicular trap horizons, weak zones, etc.) in the Deccan trap regions of the country.

Geohydrology of springs in a mountain watershed: The need for problem solving research

G. C. S. Negi and Varun Joshi

Land and Water Resource Management Division, G. B. Pant Institute of Himalayan Environment and Development, Garhwal Unit, P. B. 92, Srinagar (Garhwal) 246 174, India

Spring discharge is controlled by rainfall, land use, vegetation, grazing incidence and geomorphology of the recharge zone in a mountain watershed in Garhwal Himalaya. The decline in discharge was found low (36.4%) in a fracture/joint/colluvial related spring with SE aspect, a mix of agriculture and moderately grazed grazingland with abundance of bushes, as compared to 100% decline (dry) in a colluvial related spring with WNW aspect, agriculture and moderately grazed old-growth chir pine forest land use and a negligible amount of bushes. Springs were also characterized by (i) a peak discharge in rainy season followed by a gradual decline and negligible response to winter rains; and (ii) those who had a sharp decline from peak discharge and substantial response to winter rains. Hydrological characteristics of the springs call for research on 'spring sanctuaries' and adopt better management and technological inputs in order to cater to normal drinking water demand of the catchment people.

WATER as a natural resource and fundamental basis of existence of life is abundant in the Himalaya, but its uneven distribution both in space and time comes in the way of development needs of the region¹. Despite the fact that the mountains provide life-giving water to millions of the downstream people through perennial river system, its people face acute shortage of water during summer. People are sometimes compelled to reduce water consumption, consume unhygienic water, purchase water, and face social conflicts². Another face of the problem is soil erosion, deterioration of agricultural productivity, instability of hillslopes and landslides, and floods and associated catastrophic losses in the adjoining plains caused by the intense rainfall during rainy season^{3,4}. Springs are drying up or becoming seasonal, and the difference in the volume of water flowing down the rivers during dry and rainy seasons is commonly more than 1000 times, resulting in too-little-and-too-much-water syndrome – a common feature of the desert country⁵. Studies^{5,6} indicate that deforestation, land use change, intense grazing, reduced water retention capacity of the catchments, declining rainfall in some localities, etc. have led to diminishing discharge of the springs.

At present, in all hill areas, excluding river valleys, the main sources of sustenance are the sub-surface and

surface water flows which need adequate recharging to meet the demand. The recharging depends upon vegetational cover, in addition to the geological and geomorphological controls in the recharge zones. Geo-hydrological studies suggest that the lineaments produced by joints, fractures, and faults play a very significant role on the hydrogeological regime of a catchment^{5,7}. We still have a limited knowledge about the nature of the springs in response to rainfall, recharge zones, role of vegetation, land use in spring recharge, etc. Equally important are the technological inputs and management issues^{2,4}. This combination of interrelated factors calls for work on 'spring sanctuaries'. The present work provides spring discharge pattern in a mountain watershed, explores interaction of spring behaviour with rainfall, land use, and other morphological characteristics of the springs, emphasizes water resource management and points out the need for research and follow up action.

Located between 30°5'N and 78°46'E and 1650 m asl altitude, Dugar Gad catchment covers about 306 ha area (Figure 1). Annual rainfall (average of 1994 and 1995) amounts to 1694 mm, of which 74% occur during rainy

Average run off efficiency (%)	41.3

season. The mean monthly minimum temperature was 6°C (in January) and the mean monthly maximum was 31°C (in June). Population attributes, land use, water sources and a few other hydrometeorological features of the catchment are given in Table 1. Data of runoff and sediment loss are based on a separate study being undertaken by us in this catchment. Lack of irrigation, low yield, small and scattered holdings (10707 tiny terraces) are some of the reasons which have put about 60% of the cultivated land abandoned in this catchment. Despite a huge number of springs and 'naulas' (very shallow 1–2 m deep, appropriately lined wells to recover water from seepages) discharge in them diminishes during summer which compell people to reduce their household water consumption. Therefore, drinking water provisions and land and water conservation constitute the main challenges in this catchment.

Four springs, one each in the four villages of the catchment were selected for this study in April 1995. In addition, a near-extinct spring (Bhimli Talli-2) was selected for discharge revival employing vegetative and engineering methods. These springs differ from each other with respect to their nature, i.e. perennial (P) and seasonal (S), recharge zone area, upslope aspect, slope, land use, type of rocks and upslope vegetation (Table 2). Geologically these springs were of three types: colluvial related (Palsain; Figure 2a), fracture/joint/

Figure 2. a, Palsain – a colluvial related seasonal spring. The major land use in recharge zone is terraced agriculture and old-growth chir pine forests (in the upper zones). + sign locates the spring. b, Bhimli Talli-1, a fracture/joint/colluvial related perennial spring. The major land use is bush land and grazing land with young chir pine trees scattered in the upper zone. c, Bhimli Talli-2, a fracture/joint related near-extinct spring taken up for discharge revival experiments. The major land use of recharge zone is severely grazed land without trees.

RESEARCH COMMUNICATIONS

Table 2. Location, morphological characteristics, land use and vegetation associated with the springs in the Dugar Gad catchment

Name of the springs (village)	Upslope area (ha)	Type of the spring	Rock types	Average slope of catchment, aspect	Major land use	Vegetation of the spring catchment
Ali (S) (1440)	20.9	Fracture/joint/colluvial related	Phyllite, phyllitic quartzite	36°, SW	Forest under moderate grazing influence	Old growth chir pine (<i>Pinus roxburghii</i>) stand, bushes of <i>Berberis asiatica</i> , <i>Crataegus crenulata</i>
Bhimli Malli (P) (1550)	12.1	Fracture/joint/colluvial related	Phyllitic quartzite	12°, SE	Agriculture and grazingland under low grazing influence	Scattered young trees of <i>Celtis australis</i> , bushes of <i>B. asiatica</i> , <i>C. crenulata</i> and <i>Rubus ellipticus</i>
Bhimli Talli-1 (P) (1500)	40.7	Fracture/joint/colluvial related	Phyllitic quartzite	10°, SE	Abandoned land, shrubland and grazingland under low grazing influence	Young chir pine trees, a few trees of <i>C. australis</i> , bushes of <i>B. asiatica</i> , <i>C. crenulata</i> and <i>R. ellipticus</i>
Bhimli Talli-2 (P) (1575)	18.5	Fracture/joint related	Phyllitic quartzite	40°, SE	Open grazingland under high grazing influence	No trees, bushes of <i>B. asiatica</i> , <i>C. crenulata</i> and <i>Rhus parviflora</i>
Palsain (P) (1450)	10.4	Colluvial related	Phyllite, phyllitic quartzite	15°, WNW	Agriculture and forest under moderate grazing influence	Old growth chir pine forest, scattered trees of <i>C. australis</i>

S, Seasonal; P, Perennial; Values in parentheses indicate altitude (m asl).

*Peak discharge (litre per day); **Spring dried up; Values in parentheses indicate total annual rainfall (mm).

colluvial related (Bhimli Talli-1; Figure 2b) and fracture/joint related (Bhimli Talli-2; Figure 2c). Spring discharge was observed once in a week and daily rainfall was recorded at two locations (1460 and 1560 m asl). Discharge pattern was found highly variable across the springs (Figure 3). Bhimli Talli-2 spring recorded both minimum (15.5 l per hour on 13 June) and maxi-

mum (5571 l per h on 19 September) discharge across all the springs, registering a drop of 99.7% from the peak. In this spring of high slope (40°), discharge declined sharply. A low to moderate decline in discharge was recorded in Bhimli Malli (55.6%) and Bhimli Talli-1 (82.9%) springs, respectively. These springs were least affected by rainfall during post-rainy season

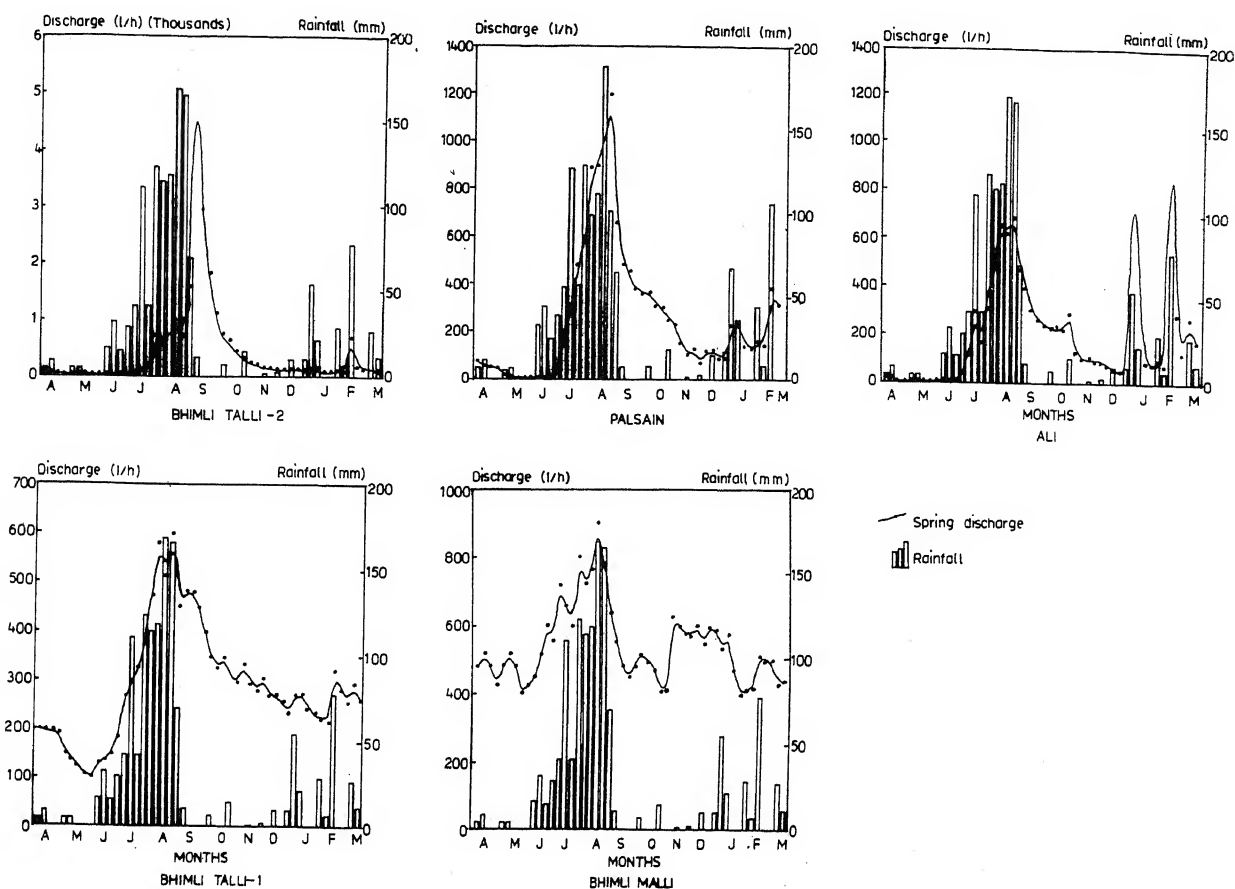

Figure 3. Spring discharge pattern in relation to rainfall in Dugar Gad catchment, Garhwal Himalaya.

(Figure 3). The upslope of these springs is rather gentle, saucer shaped and south-east facing, which allowed less exposure to sun. Recharge zone area and annual water discharge of the springs are unrelated, implying that land use and geological features were equally important. Both of them have a sizeable proportion of abandoned land with thick growth of bushes, low number of mature trees and a low incidence of grazing. Such a situation can be considered ideal for spring recharge zones. Two seasonal springs become dry for 50 days between 23 May and 11 July (Palsain) and for 63 days between 2 May and 4 July (Ali). These springs have old-growth chir pine forests in upper slopes which is under moderate grazing influence. These springs behave in close correspondence to rainfall. It can be emphasized that evapotranspiratory and interception losses, greater slope (Ali), more area under agriculture (Palsain) and year-round grazing; all work together to reduce the moisture retention capacity of the spring recharge areas and render the springs dry during summer.

Among all the springs, Bhimli Talli-2 spring was unique, with respect to land use, high degree of slope, presence of numerous rock outcrops, thin soil layer, ab-

sence of trees and most of the area under year round grazing land. Such landscapes are characterized by a lateral downslope movement of water within the soil layer via a 'quick-flow' process producing typical storm hydrographs⁷. Looking at the hydrological behaviour of these springs, it can be emphasized that each spring has its own character which is influenced by a combination of factors operated in the recharge zone.

Total discharge of the four springs, excluding Bhimli Talli-2 (taken up for discharge revival experiment) in the summer months has the potential to provide 15.6 l water per capita per day to the catchment people, only if the overflowing water is stored in suitable intake structures, distribution system is rationalized and social constraints are undermined. As a matter of fact, Bhimli Malli and Bhimli Talli-1 springs have enough discharge, which often goes waste. On the other hand Ali and Palsain springs are seasonal. People of Ali village located near road head are occasionally provided with water transported from a distant locality by district administration tankers. People of Palsain, a village occupied by the weaker section, have no other option but to dig a well at the point of origin of the dried spring and collect

the dirty water. It can be stated that water shortage is a site-specific problem and needs to be solved combining hydrological and management considerations.

Understanding the site-specific nature of the springs, their response to rainfall, land use, biotic pressure and sociological constraints and limitations of our knowledge with regard to revival of springs, the following areas of problem-solving research in this region may be suggested – (i) Water harvesting, conservation of spring sanctuaries, studying recharge and discharge pattern of springs, collection and analysis of hydrometeorological data (e.g. rainfall, runoff, evapotranspiration, water budget, etc.); (ii) traditional water conservation/management systems; (iii) identification of plants which can help in augmenting ground water recharge; and (iv) strengthening water management system and role of technological inputs to check water misuse and losses.

Recent crustal adjustments in Dehra Dun valley, western Uttar Pradesh, India

Piyoosh Rautela and D. Sati

Wadia Institute of Himalayan Geology, Dehra Dun 248 001, India

The compression that was responsible for India-Asia collision and consequent formation of the Himalayan orogen, though subdued, has not yet ceased. A large number of earthquakes occurring between the Main Central Thrust (MCT) and Himalayan Frontal Fault (HFF) bear testimony to the continuing compressional stress regime. The present study provides

evidence of recent crustal adjustments in Dehra Dun valley to the south of Main Boundary Thrust (MBT) in the form of tilted and deformed terraces, colluvial wedges, land subsidence and older rock sequences overriding the Holocene sediments. These neotectonic movements warrant detailed investigations using modern techniques in this seismotectonically sensitive area.

INDIA-Asia convergence that started about late Cretaceous, finally resulted in plate collision in early Cenozoic (45 ± 5 Ma). The deformation front successively propagated towards south. The rate of northward movement of the Indian plate relative to Siberia is estimated to be about 44–61 mm per year¹. Of this, about 10–15 mm per year is absorbed in the frontal Himalayan region while the remainder is distributed across the Higher Himalaya, Tibet, Tein Shan and further north². Some workers^{3,4} visualize MBT as the current boundary of plate convergence. Neotectonic deformation in the foreland basin of Himalaya has been studied in the Nepal sector⁵, Kumaun^{6,7} and Garhwal⁸.

The unusually wide sub Himalayan belt between the rivers Ganga and Yamuna is known as Dun re-entrant area. This area comprises of bedded Upper Siwalik sediments and Holocene Dun gravels and houses the densely populated township of Dehra Dun in the central part (Figure 1). This Dehra Dun valley has been the focus of attention since the 1905 Kangra earthquake that had one of its high intensity zones (secondary epicentre) around this city⁹. Currently this area is rising at the rate of 1 mm per year¹⁰. To map the active faults between the MBT and the HFF, a detailed geological mapping was carried out by the present authors in 1994–1995 (Figure 2).

The foreland basin in the outlined area comprises a basal sandstone succession with interbedded subordinate clays overlain by pebbly sandstone and boulder conglomerate. The boulder conglomerates exposed in the vicinity of the MBT show definite late Upper Siwalik affinity (V. Raiverman and A. C. Nanda, pers. commun.). In the field no tectonic or stratigraphic break was observed between these conglomerates and the underlying sandstone-shale succession. The entire sequence has thus been equated to Upper Siwalik subgroup exposed across Yamuna¹¹. These sedimentary rocks are deformed into a major NW-SE trending syncline, flanked on either side by two parallel trending anticlines. The syncline is largely occupied by Holocene Dun gravels. In the northern range, four fault planes paralleling the MBT have been identified between Yamuna and Rishpana rivers. The fault plane that lies immediately to the south of the MBT follows the axial zone of the northern anticline.

In the southern belt (part of southern anticline), a major zone of back-thrusting is identified between

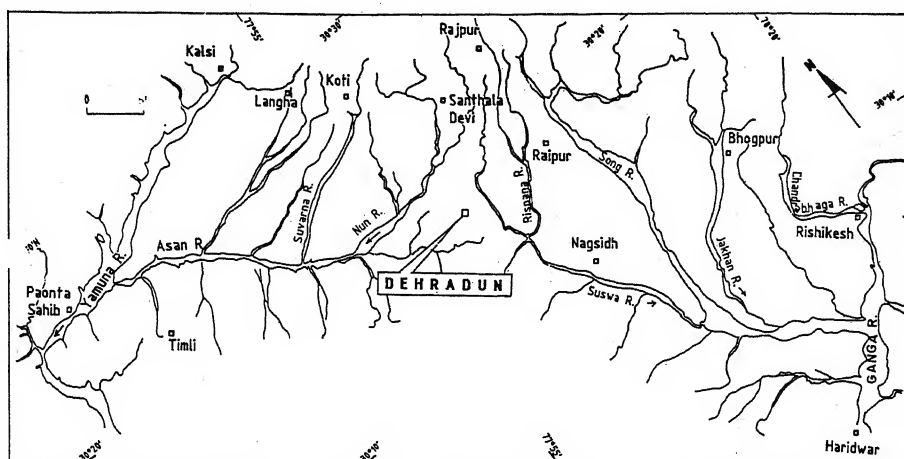

Figure 1. Location map of the area.

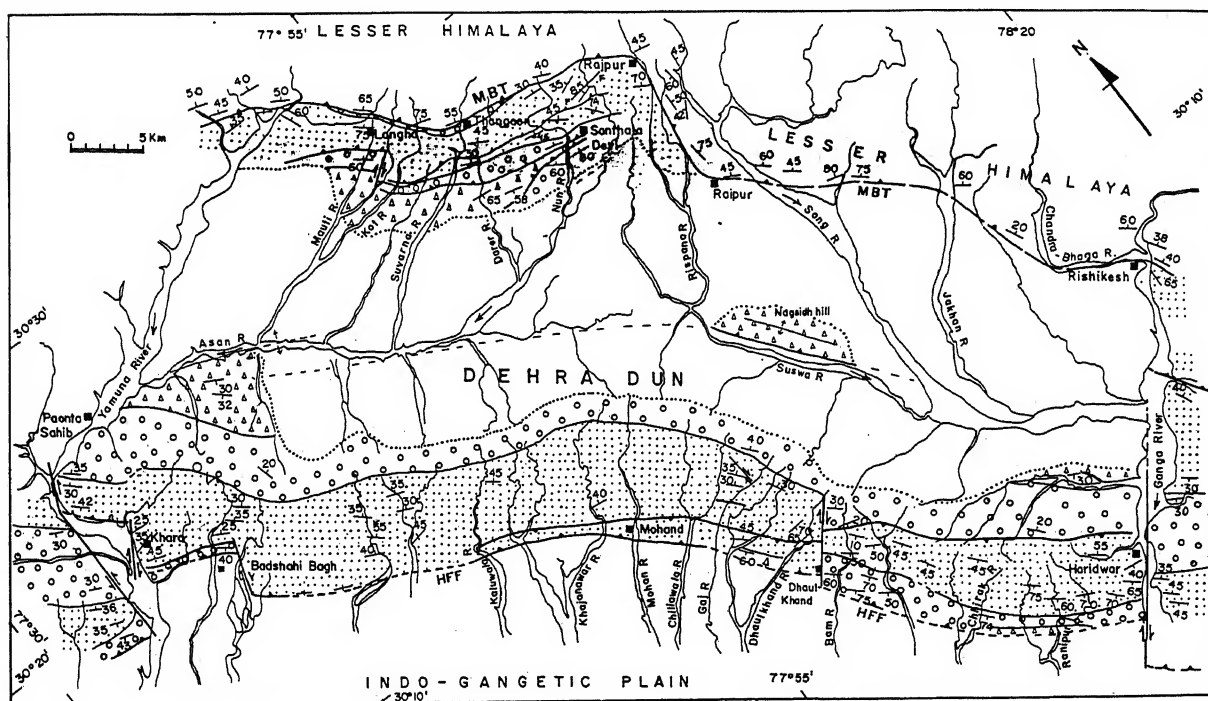

Figure 2. Geological map of the area. Indexed lithologies represent Upper Siwalik Formation. The dotted part indicates sandstone sequence with minor clay, siltstone and pebbly sandstone beds, the open circles indicate dominantly boulder conglomerates with occasional clay, siltstone and pebbly sandstone, the open triangles indicate the youngest Siwaliks deposited unconformably over the Upper Siwaliks and blank space in the central part indicates Holocene Dun gravels.

Kaluwala rao and Ganga. Three major zones of strike slip faulting have been mapped in this belt oriented along the rivers Yamuna, Dhaukhand and Ganga with approximate lateral shifts of about 20 km, 2.5 km and 11 km respectively¹².

A close interrelation between the basement configuration and the structural set up of the area is worked out on the basis of the present studies. In the southern ex-

tremity an E-W vertical fracture is inferred in the basement along which the northern block has subsided. Arrest of the south-directed thrust movement against this vertical fracture initiated back-thrusting in the southern belt. Subsidence along this fracture increases towards east and hence the back-thrusting becomes increasingly pronounced in this direction. The observed back-folds (Figure 3a) overridden by back-thrusts

Figure 3. *a*, Sandstone beds displaying a back fold structure in Khajnawar rao section. Camera views towards west. The southern limb (left hand side) of the fold is overturned; *b*, The back fold is run over by back thrust pushing the thrust slab towards the hinterland. View towards west; *c* and *d*, A north dipping shallow plane cuts across the moderately north dipping boulder conglomerate beds near Rajauli in Kot river section. The pebbles and boulders in the zone are highly fractured. A stretched pebble oriented along the fault plane indicates normal faulting (camera facing west); *e*, Thick column of un-endurated terrace sediments in Darer nala section near Manduwala showing north hading normal fault along which a colluvial wedge has developed (camera facing east).

(Figure 3 *b*) in this zone are the surface expressions of this subsurface fracture. Presence of the vertical fracture in the basement is also supported by the interpretation of the seismic profiles¹³ across the area.

Our study shows evidence of ongoing tectonic activity in the form of tilted terraces, colluvial wedges, faulting in stream terrace, active land subsidence and the older rock sequences riding over the

Figure 4. *a*, In the upstream of Darer nala (north of Manduwala) north tilted terrace (T1) is seen resting over the vertically disposed boulder conglomerate formation (BC). The tilted terraces form the base for a nearly 3 m thick fine-grained lake fill deposits (LF), succeeded upwards by unassorted II terrace (T2) of about 5 m in thickness (view towards east); *b*, Displaced terraces near village Khara indicate a zone of subsidence along a recently active fault zone (photograph taken towards west); *c*, East of Rajpur along river Rispana SW directed thrusting along an en-echelon shear plane of MBT (lying in the north) is noticed. The Precambrian Simla Unit (LH) overrides the Holocene hillwash (HW) along this fault plane (photograph taken towards ESE); *d*, SW directed thrusting close to MBT zone in Holocene river terraces near the Chandrabhaga–Ganga confluence in Rishikesh (photograph taken across Ganga on a left bank face).

Holocene sediments. These features are described below.

Tilted terraces are observed in Darer, Kot, Nun and Suvarna river sections. The tilt of the terraces varies between 15 and 25°. A shear zone is recorded in the Upper Siwalik conglomerates in the Kot river section. The conglomerate clasts are shattered and differentially displaced along the shear zones. One of the pebbles was found to be sliced (Figure 3 *c* and *d*). The sense of movement along this NE dipping shear plane is of normal type. The NE trending normal faults in this unit have

been produced due to sudden upliftment of the footwall block and consequent collapse of the hanging wall.

In the Darer river section near Manduwala, a colluvial wedge is observed in a 20 m thick river terrace (Figure 3 *e*), suggesting normal faulting. The fault plane dips 35° towards NE. The terrace deposits are bedded, but poorly assorted and without appreciable breaks. The terraces are tilted towards the north, suggesting uplift in the Quaternary times along a sub-vertical fault parallel to the MBT. This relative uplift of the block caused local ponding in which the fine sediments were deposited

Figure 5. Geological cross-section along Ranipur-Motichur bypass road section in the southern Siwalik belt. The inset shows the pop-up structure in the HFF zone uplifting the Holocene sediments. Geology is as per Figure 2.

in the terraces (Figure 4a). Northward tilted terraces are also observed along stream sections lying to the east of Nun river. A zone of subsidence occurs along a recently active fault to the northwest of Santhaladevi shrine. The land has subsided by about 5 m (Figure 4b).

To the east of Rajpur along the Rispana rao section, an active en-echelon thrust of MBT is identified. Along this thrust, the Lesser Himalayan rocks are overriding the Holocene sediments (Figure 4c). Friction clays and carbonaceous matter are observed along this contact. Similar activities have been noticed near Ganga-Chandrabhaga confluence (on the left bank of river Ganga), Rishikesh where southwest-directed thrusting along a shear plane is observed in the river terraces (Figure 4d).

In the core of Dun syncline an E-W trending thrust has been identified along the southern border of Nagsiddh hill situated to the south of Rajpur. This shallow N-dipping thrust plane brings a folded anticlinal structure in the youngest unit of the Upper Siwaliks (shown by open triangles in the map) over the Holocene gravels and boulders in the synclinal basin. The fault is not exposed towards Yamuna but an anticlinal structure delineated along Asan is indicative of its blind nature. In Dehra Dun city itself, prominent NW-SE (310° - 130°) oriented fractures were observed in a large number of houses in a residential colony across river Rispana. These fractures are continuously opening up. The detailed studies are underway.

Evidence of neotectonic movements is also found along the HFF zone in the southern Siwalik belt between Chhirak rao and Ranipur rao. Here the youngest Upper Siwaliks containing unconsolidated, poorly stratified, boulder-pebble sequence in clay sand matrix display an open NW-SE striking anticline. This structure has formed within a pop-up setting between two thrust faults in the HFF boundary (Figure 5). In a nala section to the east of Bam rao, the displaced pebbles in the conglomerate unit along a SSW dipping shear plane suggest NE directed back-thrusting. Similar structures also occur in the Bam rao section. Neotectonic deformation is also reported in the Dhaukhand strike-slip fault zone along the Gaj rao⁸. Neotectonic adjustment of the rocks here was shown to be responsible for the uplift of the river

bed. From the presented evidence, three distinct neotectonically active domains have been identified: (i) the northern Siwalik belt experiencing active normal faulting, (ii) the central zone with south-directed thrusting and (iii) the southern belt with prominent back thrusting (north directed thrust movement).

Neotectonic movements show active ongoing movement related to the N-S compression responsible for Himalayan mountain building. This compression has not yet ceased and is causing strain in the foreland basin of Himalayas as manifested by the observed structures. Evidence of both SW-directed thrusting, NE-directed back-thrusting together with normal faulting recorded in the area suggests that the deformation is dominantly being controlled by the basement topography. The presence of active thrusting along an en-echelon shear of MBT and a thrust plane on the southern margin of the Nagsiddh hill in the eastern part of the area indicate that movement along HFF has almost ceased and currently some part of the strain is being released along these newly-formed shear surfaces.

The plague outbreaks of India, 1994 – A prologue

V. Ramalingaswami

All India Institute of Medical Sciences, Ansari Nagar, New Delhi 110 029, India

PLAGUE is a disease of great antiquity in India. India was one of the countries most severely affected by the Third Pandemic of plague which spread around the world through steamships; there were an estimated 12.5 million deaths due to plague between 1886 and 1950 in India¹. In his autobiography *My World of Preventive Medicine*, C. G. Pandit recollects the night sky of Bombay lit up every night by the rising flames of burning bodies, dead from plague in the early part of this century². From 1950 onwards with the increasing availability of DDT and broad-spectrum antibiotics, plague transmission was gradually curtailed and mortality from the disease much reduced. India's Haffkine Institute played an important role in the history of plague in developing an anti-plague vaccine as early as the turn of the century followed later by treatment trials of patients affected with plague. By 1967, interruption of wild plague transmission to humans appeared to have been achieved in India and human plague outbreaks were no longer reported. Between 1967 and 1993 there were reports of two separate outbreaks of plague but neither of them was confirmed as plague³. It is well known that plague cannot be eradicated just as small-pox was and poliomyelitis would hopefully be in the near future. It is a disease of the earth, of the creatures that run and burrow the earth and of the fleas. Man is an accidental victim and need not have plague infection for plague persistence. In recent decades, plague had simply retreated to rural natural foci of infection, involving mostly wild rodents and their fleas with occasional spillovers to commensal hosts and humans in villages and towns¹. Many natural foci of plague in wild rodents exist today not only in India but throughout the developing world in the continents of Asia, Africa and Latin America. Meanwhile, there had been a shift in plague mortality and morbidity from its dominance in Asia in the 1960s and 1970s to Africa in the 1980s and 1990s with case fatality rates still remaining high.

But epidemics of human plague can be prevented from occurring and controlled with present-day knowledge and methods of surveillance, prevention and treatment. This is what did not happen in India, repeating the usual story of complacency following initial victory against communicable disease⁴. Unstable epizootic factors with

hostless fleas are conducive to the outbreaks of human plague.

Thus it was that between August and October, 1994 India was struck by two outbreaks of plague in succession – one of suspected bubonic plague in the Beed District of the State of Maharashtra and the other of suspected pneumonic plague in the Surat city of the State of Gujarat. On the basis of circumstantial and serological evidence the outbreaks were presumed to be plague and they were rapidly brought under control by governmental action at the State level assisted by the Centre. In the process, however, India's vulnerability to emerging and re-emerging infectious diseases was exposed on many counts, especially in the areas of epidemiological monitoring and supportive laboratory services, the essential pre-requisites for rapid response. As the WHO International Team investigating the plague outbreaks in the country said in its Executive Report dated 22 November, 1994, while the outbreaks were raging, there were problems with the investigating laboratories in being able to quickly differentiate real cases of plague from the huge background load of a variety of infectious diseases which also cause epidemics with similar clinical and epidemiological features⁵. 'Diagnosis became overly dependent on procedures that are used to support a diagnosis of suspected plague (Gram stain, Wayson stain of smears prepared from clinical materials). A similar over-reliance was placed on serologic procedures that support a diagnosis of presumptive (probable) plague. (Single serum specimen testing using passive haemagglutination assay)'⁵. May C. Chu, the microbiologist member of the WHO International Team, who comes from the WHO Reference Laboratory for Plague at the CDC in Fort Collins, Colorado, USA, said on November 18, 1994: 'Though there were multiple attempts to isolate *Yersinia pestis* from sputum, blood and autopsy specimens, there is no clearly-identified *Y. pestis* culture associated with any specimen obtained from suspected plague patients.'⁶ Thus in those early days, diagnostic uncertainty and confusion prevailed; alternative diagnoses implicating other infectious agents were offered and there was panic and excessive alarm on the part of the public, coupled with widespread reporting by the media. The message

did not go through effectively that in the modern era with its array of insecticides, diagnostic and therapeutic tools, today's plague is not the Black Death of olden times and is readily amenable to prevention and control through a system of surveillance and prompt response. Fifteen airlines cancelled 400 flights to India, resulting in much economic damage.

Against this background, on 9 October, 1994, by which time the two outbreaks had largely subsided, the Government of India constituted the Technical Advisory Committee (TAC)* on Plague with the following Terms of Reference:

1. To elucidate factors responsible for the current outbreak of plague and its spread;
2. To advise on strategies, policies and programmes for the control of plague;
3. To recommend steps for prevention of such outbreaks in future.

TAC initiated work on all the three Terms of Reference but even at the outset it was clear that the on-going controversy in the media and in professional circles as to whether it was plague or not would not abate until conclusive evidence of the identity of the causative agent was found. And unless this was done, TAC could not proceed with addressing its Terms of Reference.

There was, however, a major snag. The outbreaks had largely subsided by the time TAC was formed and so it was not possible for TAC to collect and study fresh material for laboratory confirmation of human plague through isolation of *Y. pestis* from clinical specimens. TAC had to have recourse to the original clinical specimens obtained while the outbreaks were 'on' and stored in Surat and at the National Institute of Communicable Diseases (NICD) in Delhi. The WHO International Team had remarked that attempts at culture isolation and identification of *Y. pestis* at both these places had failed to yield pure characterizable colonies⁶. Contamination of bacterial isolates was a problem. TAC then decided to mobilize the expertise and laboratory facilities available within the country, including those with some members of TAC for this task. Both the new Civil Hospital in Surat and NICD, Delhi, had extended their full cooperation to TAC in providing the stored cultures

for TAC's study. The Defence Research and Development Establishment (DRDE) in Gwalior (H. V. Batra) had undertaken the main task of isolation and characterization of *Y. pestis* from the stored cultures and further molecular characterization of the isolates in a pure form was carried out by scientists working in a network of laboratories functioning under various research agencies in India. Scientists in the following institutions played a key role in this effort: the All India Institute of Medical Sciences (AIIMS) (S. K. Panda); the Post-Graduate Institute of Medical Education and Research (PGIMER), Chandigarh (N. K. Ganguly); the Institute of Microbial Technology (IMTECH), Chandigarh (Amit Ghosh); and the Centre for Cellular and Molecular Biology (CCMB), Hyderabad (S. Shivaji). Meetings of the scientists from these institutions were held from time to time and there was a spirit of cooperation and team work amongst them in this endeavour. H. Sharat Chandra of the Indian Institute of Science, Bangalore and a member of TAC coordinated this work. In addition to clinical material from Surat, specimens of original rodent material and of fleas from Surat and Beed collected by NICD scientists during and after the outbreaks were made available to TAC for culture isolation. In the entire work done by TAC and the expert panel to track down the infectious agent, the Health Departments of the State Governments of Maharashtra and Gujarat gave their utmost cooperation.

The result was that *Y. pestis* could be isolated and characterized as such from some of the clinical samples in Surat and from the environmental samples in Beed and Surat. In this issue of *Current Science*, a number of articles appear, narrating the story of isolation and characterization of *Y. pestis* and providing TAC's response to the Terms of Reference. At first there is an overview of the work done by TAC followed by a series of articles on the isolation and characterization of *Y. pestis* from the clinical and environmental samples, the serological evidence, a special article on molecular characterization of *Y. pestis* isolated from the outbreaks, followed by ecological aspects of the outbreaks. These articles are written by scientists who had carried out the work in their laboratories. In the end, the epilogue looks at the future scenario – what next?

An overview of the work carried out by the Technical Advisory Committee on plague

DURING August, 1994 the village Mamla of Beed district of Maharashtra State experienced unusually heavy flea nuisance and ratfalls. Subsequently, a number of cases clinically resembling bubonic plague were reported from Mamla and nearby villages of Beed district. Making a presumptive diagnosis of bubonic plague outbreak and based on the totality of ecological, clinical and serological evidence, the health machinery of the State Government with the support of the Central Government took prompt containment measures.

During September, 1994, government hospitals and private clinics in the City of Surat in the neighbouring State of Gujarat reported an increasing number of patients with a highly fatal illness resembling acute pneumonia. Based on clinical, laboratory and radiological findings a presumptive diagnosis of an outbreak of pneumonic plague was made. The State Government, again with the active support of the Central Government, rapidly instituted containment measures.

The establishment of the Technical Advisory Committee (TAC) on plague, its terms of reference and pattern of working are described in the prologue.

It was plague after all – the evidence

The organism

DRDE, Gwalior had succeeded in obtaining pure cultures of *Y. pestis* in 11 out of 82 samples processed by them from patients suspected of pneumonic plague from Surat. They also succeeded in obtaining 6 *Y. pestis* isolates from different batches of trapped rodents from Beed within a year of the outbreak and another single rodent isolate from Surat City from among 17 animals in August, 1995. Confirmation and characterization of *Y. pestis* was done according to standard procedures such as gross characteristics, colony morphology, staining, biochemical tests, fluorescent antibody to F1 antigen, specific bacteriophage lysis, counter-immuno-electrophoresis and SDS-PAGE analysis. H. V. Batra *et al.* describe (page 787) this work in the paper 'Isolation and identification of *Yersinia pestis* responsible for the recent plague outbreaks in India'.

Confirmation that a case or an outbreak is one of plague rests on cultural isolation of *Y. pestis* from clinical specimens obtained from patients with clinical and epidemiological features compatible with plague. The

isolates should show lysis by specific bacteriophage and a biochemical profile indicative of *Y. pestis*. This has now been accomplished. The long gap in processing specimens from the time of their collection and attempted culture with consequent deterioration, and the heavy overgrowth of contaminating organisms made culture isolation a difficult process and may explain the low yield of positive cultures for *Y. pestis* (11 positive out of 82 pneumonic patients of Surat city). It is of interest that 9 out of 11 positive cultures were from patients in the early days of the outbreak, presumably before widespread antibiotic use in the community.

Plague can also be confirmed through the passive haemagglutination (PHA) test by demonstrating a four-fold difference in serum antibody titre between specimens taken at appropriate intervals (minimum of 2 weeks) and by demonstrating their specificity for the F1 antigen of *Y. pestis* as determined by haemagglutination inhibition (HI). The serological investigations in Beed and Surat outbreaks were handicapped by lack of availability of paired serum samples at appropriate intervals. Acute phase sera were generally not available. Serological evidence of plague in this study rests largely on high antibody titres in a majority of the serum samples (85.2%) taken from patients in Surat convalescing 2 to 3 months following illness. It is important to note, however, that in all cases, the specificity of passive haemagglutination test was ensured by simultaneously performing a haemagglutination inhibition (HI) test. These results, taken together with specific sero-reactivity to the F1 antigen in humans and dogs in Beed and Surat, reported by the WHO International team provide further confirmatory evidence that the outbreaks in Beed and Surat were due to *Y. pestis* infection. The serological work is presented in this series in the paper entitled 'Passive haemagglutination tests for *Y. pestis* infection in Surat pneumonic patients' by G. S. Agarwal and H. V. Batra (page 792).

Tissue pathology

Small tissue samples made available to the TAC from 7 autopsies from the New Civil Hospital were examined histopathologically. While showing no consistent pattern of pathology, there was a variable picture consisting of some cases showing intra-alveolar oedema, haemorrhage and a pneumonic process in the lungs of varying sever-

ity. *Y. pestis* could not be demonstrated in these tissue sections.

Molecular characterization of *Y. pestis* isolates

Molecular characterization of bacterial isolates from pneumonic plague patients in Surat and from rodents and fleas in Beed and Surat together with PCR analysis of tissues obtained at autopsy of 7 patients who died of pneumonic plague, provided a valuable dimension to the study of the Indian plague outbreaks of 1994. These aspects are discussed (page 794) in the paper entitled 'The 1994 plague epidemic of India: Molecular diagnosis and characterization of *Yersinia pestis* isolates from Surat and Beed' by S. K. Panda and coworkers in this series.

PCR analysis of autopsy tissues from the 7 patients who died of pneumonic plague, using primers for *Y. pestis*-specific *pla* and *f1* genes revealed that 5 were positive for *f1* gene and 2 for the *pla* gene. The results provided unequivocal evidence of tissue invasion by *Y. pestis* and a further confirmation of the Surat outbreak being plague. This is perhaps the first time that *in situ* demonstration of *Y. pestis* in historical material has been attempted successfully.

All the 18 bacterial isolates (11 from human cases in Surat and 7 from rodents in Beed and Surat) were positive for the presence of *pla* and *f1* genes by PCR.

Ribotyping has proved to be an extremely useful tool for molecular typing of *Y. pestis* isolates. Upon ribotyping, the Indian isolates were identical to one another, whether derived from patients with pneumonic plague or from rodents of Beed and Surat but differed from all the *Y. pestis* strains examined so far by Elizabeth Carniel of the Pasteur Institute, Paris at the WHO Reference Centre on *Yersinia*. Although different from the 16 previously known ribotypes, it does not follow that the Surat strain is new and of recent origin since only 85 of the approximately 6000 *Y. pestis* isolates known to exist in *Y. pestis* collections worldwide have so far been ribotyped. It is noteworthy that Surat and Beed seem to harbour *Y. pestis* of the same ribotype.

Pulsed field gel electrophoresis confirmed that all the three plasmids of *Y. pestis* of molecular weights 7.5, 75 and 110 kb were present in the Surat isolates. This implies the presence of virulence-associated genes and also the conservation of F1 antigen as demonstrated by immunoblotting, giving confidence to the F1-based serology for diagnostic and epidemiological work.

With regard to the presence of an extra protein band in the 25 kd region of Surat strains, initially observed in joint studies carried out at the WHO International Reference Centre on Plague at Fort Collins, Colorado, USA, it is not clear what significance should be attached to this protein band.

What does all this mean? The molecular identity of *Y. pestis* isolates from human cases of pneumonic plague in Surat and of 6 *Y. pestis* isolates from different batches of trapped rodents from Beed within a year of the outbreak and a single rodent isolate from Surat suggest that that isolates were clonal in origin; the possibility is also raised of an epidemiological linkage among them. The organisms that were obtained from both locations might have been derived from pre-existing ones in each of the areas. The possibility that the organisms might have travelled through the movement of rodents and humans cannot be ruled out, given the fact that frequent movement of rodents and their household effects are known to take place between Beed and Surat.

The molecular identity of the isolates from human cases in Surat and of the isolates from environmental samples (rodents) from Beed and Surat plus the fact that 5 out of 7 flea samples collected during the outbreak period were positive for the *f1* gene of *Y. pestis* suggest that plague was endemic in natural foci in these areas, possibly generating human outbreaks consequent upon major changes in human ecology. Two papers presented in this series entitled 'Ecology of flea-transmitted zoonotic infection in village Mamla, District Beed' (page 800) and 'Observations on urban ecology of Surat and bubonic plague transmission in the city' (page 803) by V. K. Saxena and T. Verghese throw interesting light on this problem. All in all, TAC was of the opinion that the evidences obtained so far do not indicate that the isolates of *Y. pestis* from the plague outbreaks in India 1994 were the product of genetic manipulation and introduction from outside, a popular theory in the media at that time. Admittedly, there are many gaps in our knowledge of the Indian plague outbreaks of 1994 – bubonic plague in Beed and pneumonic plague in Surat and what connection there may be between the two – which only a continued and active programme of research can fill.

Epidemiological and ecological aspects

As far as the eco-epidemiological background to the outbreak of suspected bubonic plague in the Beed district of Maharashtra is concerned, village Mamla was the index village and the cascade of evidence is as follows, as constructed by the Directorate of Health Services of Maharashtra state:

September, 1993: Earthquake in the neighbouring district of Latur.

September 1993 to July, 1994: Abandoned homes, stored food grains left behind, exponential growth of rat population.

5 August, 1994 onwards: Unusual flea nuisance in Mamla, followed by rat falls in the locality.

26 August, 1994 onwards: Cases with fever and lymphadenopathy started to appear and were reported at the

nearest Primary Health Centre in Kuppa in the area, mass antibiotic prophylaxis and insecticide spraying started on 29 August.

8 September, 1994 onwards: Seropositivity for plague first reported, rising in frequency later, containment measures continued.

20 October, 1994: No new cases reported.

25 October, 1994: WHO declared that the outbreak had been contained.

With regard to the Surat outbreak, during the first week of September, 1994, the monsoon was unusually heavy, a record in the past 25 years; flood waters entered the city and remained stagnant for 5 days; a large number of dead animals were found after the floods receded. Then came the Ganapati festival with close intermingling of huge crowds of people. On 19 September, 1994, an illness characterized by fever, cough, haemophysis, dyspnoea and pulmonary infiltrates on X-ray, in young adults, not responding to penicillin and attended by high initial mortality broke out in Surat city. A suspected clinical diagnosis of pneumonic plague was made by the physicians at the New Civil Hospital, Surat. The patients responded well to tetracycline, aminoglycosides and chloramphenicol. Case fatality rates came down rapidly after the high levels in the first few days. Blood specimens obtained from patients with suspected pneumonic plague revealed sero-positivity to the F1 antigen of *Y. pestis* in 146 out of 1027 samples in a study by the NICD. Reference had already been made to the study by DRDE, Gwalior, wherein 85.2% of serum samples from patients convalescing from what clinically looked like pneumonic plague were positive for antibodies to F1 antigen. Some evidence exists of a clustering of cases and death; taking of antibiotics had a beneficial effect in preventing deaths. The State Health and Civic authorities responded rapidly by instituting active case detection and treatment, providing accurate information to physicians and public on early detection, case management, antibiotic prophylaxis and treatment. 500,000 persons left Surat city in panic to other places in Gujarat, to Bombay and to various destinations in the country, but in none of the urban centres of Bombay, Calcutta and Madras was there any confirmation of plague transmission. The one patient in Delhi who had an enlarged painful lymph node in the right groin with a four-fold rise in titre after haemagglutination inhibition actually travelled to Delhi from rural Maharashtra. No imported plague was reported in any other country.

The lessons learnt

Surveillance of plague is weak in India and needs to be considerably strengthened and expanded. Prompt action to identify the causative agent in a suspected outbreak is of the utmost importance and capabilities for identifica-

tion of plague bacillus as the aetiological agent need strengthening. State Public Health Laboratories are in need of considerable upgrading of skills to make prompt and accurate diagnosis of plague and other infectious disease agents. Paradoxically, while there is expertise in the country for the study of microbes at sub-cellular and molecular levels, diagnostic capability for the isolation and characterization of common infectious agents at the peripheral levels of the health care system is weak. As a result, a vulnerability in India's health care system relating to rapid diagnosis of infectious disease outbreaks exists. There is little preparedness in the provision of Quality Laboratory Services for accurate confirmation of clinical diagnosis. Current plague experiences revealed that rapid mobilization of institutions and experts around the country in time could have helped in the prompt identification of the causative organism. Proper interaction with the media and the public and seeking their assistance are of critical importance. With the information technology available today, much of the surprise and panic among the national and international communities could have been avoided.

Future prevention and control of plague

Surveillance and response should be regarded as the foundation of infectious disease control, be it plague or any other. India has the potential of being well-served in this regard because of the extensive health infrastructure built over the past few decades. This structure is, however, somewhat handicapped by inadequate interaction between the various levels of care and the network of laboratories existent in the country. Prompt backup support of laboratory services of quality in determining the aetiological agent expeditiously must be ensured in future strategies. A national surveillance and response system in India for the control and prevention of infectious diseases is an urgent necessity. TAC has recommended the following steps:

1. Organize a national debate on the strengths and weaknesses of the existing surveillance system and draw up priorities and build on existing strengths.
2. This should lead to the formation of a National Apex Committee on Surveillance and Response for the Control of Plague consisting of appropriate experts from different disciplines and government and non-government sectors. The committee should be headed by an epidemiologist of eminence.
3. Epidemic preparedness should be integral to the control strategy.
4. The formation of a multi-disciplinary action group would be valuable. The group may consist of an epidemiologist, a clinician, a microbiologist and relevant public health and civil authorities. The group will provide guidelines for case definition,

case management, preventive action and information and communication. The National Reference Centre for plague, which in this case, is the NICD, needs to be strengthened in its microbiological and molecular genetic capabilities. There could be different national reference centres for different diseases depending upon expertise availability.

5. A network of laboratories throughout the country must be identified for providing support to the diagnosis of infectious diseases. The surveillance must include surveillance of emerging drug resistance of plague and other pathogens.
6. NICD and the network should be involved in a continuous process of training and re-training of professionals and technicians in the investigation of plague outbreaks and in establishing aetiology.
7. The capacity for continuous surveillance of animals, vectors and human populations for plague within the overall infectious disease surveillance system has to be developed and maintained. The

state and district health services should be the focal points of this system with assistance from the NICD and the national laboratory network.

8. The capacity to respond to plague outbreaks in humans and plague epizootics must be ensured through the development of epidemiologic, ecologic and laboratory investigative capacity.
9. An automated reporting system extending from health centres and laboratories to public health action programmes would be of value.
10. The TAC makes a strong plea for building a well-trained cadre of epidemiologists in the country and in this, medical colleges, schools of public health (where are they?) and specialized institutions devoted to the study of infectious diseases under the ICMR and the NICD will have to play an important role.
11. The value of continuous interaction of the national networks with international networks under WHO and others is inestimable and must be maintained.

INDIAN INSTITUTE OF SCIENCE BANGALORE 560 012

FACULTY POSITIONS at the level of ASSISTANT PROFESSOR in the Department of Mathematics are open in the following areas of Pure and Applied Mathematics: Analysis, Algebra, Geometry, Topology, Number Theory, Discrete Mathematics, Differential and Integral Equations, Numerical Analysis, Probability and Statistics, Stochastic Processes, Nonlinear Waves, Continuum Mechanics, Magnetohydrodynamics and Plasma Physics, Dynamical Systems.

Indian citizens who wish to apply should have Ph D with First Class in the preceding degree, 3 years post-doctoral experience and an outstanding research record, potential for independent research and academic leadership. Interested applicants may send curriculum vitae, research plan for future work and names and addresses of three referees to **Prof. S. V. Subramanyam, Chairman, Division of Mathematical & Physical Sciences, Indian Institute of Science, Bangalore 560 012, on or before 30 December 1996.** Simultaneously the referees may be requested to send their assessment of the applicant directly and confidentially to **Prof. S. V. Subramanyam.**

Candidates with good background in Mathematics and a strong motivation towards applications and interdisciplinary work will be preferred. Selected candidates will be required to contribute to teaching, research and other programmes of the Department and the Institute.

Isolation and identification of *Yersinia pestis* responsible for the recent plague outbreaks in India

H. V. Batra, Urmil Tuteja and G. S. Agarwal

Division of Microbiology, Defence Research and Development Establishment, Jhansi Road, Gwalior 474 002, India

The district of Beed in Maharashtra state, India experienced a suspected bubonic plague outbreak in August, 1994. A month afterwards, Surat city, in Gujarat state was in the grip of an epidemic with a highly fatal illness resembling pneumonia. The present work describes the isolation and identification of *Yersinia pestis*, the causative agent of plague, from these outbreak areas. Eleven *Y. pestis* isolates were recovered from 82 pneumonic patients of Surat city. From Beed district, 6 *Y. pestis* isolates could be obtained from different batches of trapped rodents within a year of the outbreak. A single rodent isolate from Surat city was obtained from among 17 animals in August, 1995. Characterization of the *Y. pestis* isolates was done by biochemical tests, specific bacteriophage lysis, counter immunoelectrophoresis, fluorescent antibody test and SDS-PAGE analysis.

PLAGUE epidemics and pandemics have had devastating effects on human beings throughout the recorded history. It was a highly dreaded and fatal disease in the pre-antibiotic era and at times wiped out nearly half the human population in the affected countries. Worldwide, in the post-antibiotic period, plague has existed mainly as a sporadic disease with occasional epidemic outbreaks. According to WHO reports, between 1980 and 1986, many countries in Africa, Asia and America covering a substantial proportion of the globe had reported plague cases¹. During the last decade, outbreaks of both bubonic and pneumonic forms have occurred in Myanmar, Vietnam, Tanzania, Zaire, Peru and Madagascar².

In India, plague along with cholera and small pox formed the 'trinity' of major epidemic infections until the 19th century and thereafter plague outbreaks continued up to 1968 with final disappearance in 1969. Though suspected outbreaks were reported in Maharashtra in 1975 and in Himachal Pradesh in 1984 (ref. 3), but conclusive evidence was lacking. Thus, after the disease was thought to have been conquered, suspected cases of bubonic plague were reported in village Mamla, District Beed of Maharashtra in August, 1994 following typical sequences of flea nuisance and rat falls. Within a

month the industrial city of Surat in the neighbouring state of Gujarat reported an increasing number of patients with a highly fatal form of acute pneumonia. During the period 21 September – 20 October, 1994 a total of 1027 suspected cases were admitted to hospitals in Surat city, of which 146 were recorded as presumptive pneumonic plague based on seropositivity.

We report here the confirmatory evidence of *Yersinia pestis* isolation from human pneumonic patients of Surat city and from the rodents of both the outbreak areas.

Materials and methods

Human samples

Since during the suspected bubonic plague outbreak in district Beed no bubo aspirates or blood samples were available, *Y. pestis* isolation could not be attempted from human cases. From among the patients in Surat presenting a clinical picture of acute pneumonia with fever, cough, haemoptysis, dyspnoea affecting mainly the young adults, 82 sputum specimens could be processed for isolation work. Samples were collected by the Department of Microbiology, Surat Medical College, Surat.

Rodent samples

Tissue samples of spleen and liver from 30 rats (*Rattus rattus*) of Mamla village, district Beed and 4 rats (*Rattus rattus*) from Surat city were collected during August to November 1994. During the months of April and May, 1995, 11 rats (*Rattus rattus*) and in July and August, 53 rats (*Rattus rattus*) trapped from Mamla village and the adjoining Chinchoti village of district Beed were processed. At the same time 17 rodents belonging to *Tatera indica* trapped from the field areas around these villages were also processed for isolation work. Spleen and liver of these animals were kept in Cary Blair transport medium and processed in the laboratory. From the Surat city in the month of July and August, 1995, 17 *Rattus rattus* trapped from the household vicinity of the affected

four localities were also processed. Majority of rodent samples from outbreak areas were received through the dedicated efforts of Shyamal Biswas and his team of Plague Surveillance Unit, NICD, Bangalore.

Isolation procedures

The samples were either streaked directly or after 1 to 2 days incubation in peptone water/brain heart infusion broth at 28°C onto brain heart infusion agar (BHIA), desoxycholate citrate agar and blood agar (BA). Media used were from Diffco Laboratories. The agar plates were incubated at 28°C and 37°C for 24 to 48 h. All the samples yielded mixed growth of organisms. The suspected colonies were purified by repeated sub-cultures and tested for oxidase reaction, Gram staining and Wayson staining. The oxidase negative, Gram negative and Wayson bipolar safety pin positive colonies were processed for biochemical reactions. The biochemical tests performed were indole production; citrate utilization; hydrogen sulphide production; urea hydrolysis; fermentation of glucose, lactose, mannitol, sucrose, maltose, arabinose, xylose, rhamnose, adonitol, dulcitol, cellobiose and salicin; decarboxylation of lysine and ornithine; hydrolysis of arginine.

Bacteriophage lysis

Organisms exhibiting biochemical reactions characteristic of *Y. pestis* were subjected to bacteriophage lysis test. *Y. pestis* monospecific bacteriophage kindly supplied by May C. Chu (WHO Collaborating Center, CDC Laboratory, Fort Collins, USA) was utilized for the test. Phage lysis test was performed using bacteriophage reagent on streaked pure cultures on blood agar plates and incubated at 28°C. *Y. pseudotuberculosis* strain 1 A and *Y. pestis* strain A1122 kindly provided by May C. Chu through Technical Advisory Committee on Plague, Govt. of India, served as controls.

Fluorescent antibody test

A loopful of heat killed overnight broth cultures of four *Y. pestis* isolates, *Y. pseudotuberculosis* strain 1 A and *Y. pestis* strain A1122 fixed with precooled acetone were tested following standard protocol using rabbit anti F1 FITC conjugate received through the courtesy of WHO Reference Centre using Nikon Microphot Universal microscope.

Counter immunoelectrophoresis

Wells were punched off at a distance of 5 mm in agarose (0.8% in veronal buffer, pH 8.6) coated on grease-free

clean glass slides. Wells, towards cathode were filled with crude antigens of *Y. pestis* isolates and other bacteria (*Y. pseudotuberculosis*, *Y. enterocolitica*, *Escherichia coli*, *Klebsiella pneumoniae* and *Salmonella typhi*) prepared by sonication (5 watts, 20 cycles of 60 seconds each using Misonix ultrasonicator) of harvested growth from solid media. Hyper immune sera raised in rabbits against purified F1 antigen of *Y. pestis* was added in the well towards anode. Counter immunoelectrophoresis (CIE) was carried out in an anodic current of 20 mA for 45 min using 0.075 M veronal buffer, pH 8.6 as per the method of Grabar and Williams⁴. After this the slides were incubated at room temperature overnight and washed with normal saline before staining with Coomassie brilliant blue.

Polyacrylamide gel electrophoresis

Bacterial cells were grown on blood agar overnight at 28°C from a single colony. The sodium dodecyl sulphate polyacrylamide gel electrophoresis (SDS-PAGE) was run as per the method of Laemmli⁵. Briefly, the cells were pelleted and washed in 0.5 M phosphate buffer saline. The pellets were resuspended in 50 µl distilled water and 50 µl SDS-PAGE loading dye. The samples were boiled for 4 to 5 minutes and run in a 10% acrylamide gel at 25 mA till the dye front was close to the bottom of the gel using electrophoresis unit of Atto Corporation. The protein bands were visualized by staining with Coomassie brilliant blue as per the standard protocol.

Results

The colony characteristics of suspected *Y. pestis* isolates on BA and BHIA were not clear following 24 h incubation as the colonies were barely visible. At 48 h, the size of the colonies increased to 0.5 mm in diameter and upon further incubation the size could reach up to 1–2 mm. The colonies on BA were greyish, non-mucoid, round and dome-shaped with a tendency of flattened irregular border on prolonged incubation. At times the appearance of the colonies typically resembled fried egg shapes (Figure 1).

The microscopic appearance of the organisms was coccobacilli to rods with rounded ends and slightly convex sides. Typical bipolar safety pin shapes were visible from young cultures in broth medium following Wayson staining (Figure 2). Organisms in the broth did not produce turbidity, instead floccular deposits at the bottom and rising along the walls of the tubes were very consistent and characteristic (Figure 3).

The suspected *Y. pestis* isolates from human and rodent samples showed positive biochemical reactions to

Figure 1. Colonies of a clinical *Y. pestis* isolate on blood agar plate following 72 h incubation at 28°C.

Figure 2. Wayson staining of a clinical isolate of *Y. pestis*.

glucose, mannitol, maltose, arabinose, xylose, salicin and scored negative in the remaining tests.

A total of 22 isolates exhibited these biochemical reactions. However, only 18 isolates could be lysed by the specific bacteriophage. SDS-PAGE revealed a characteristic uniform protein profile for all the 18 bacteriophage positive isolates (Figure 4 *a, b*); the other four biochemically resembling isolates had a very different pattern. Though the pattern of protein bands of the 18 isolates was nearly identical, a slight variation in the region of 34–35 kDa was observed for isolate numbers 9, 10 and 12, wherein a doublet could be seen that was not there in the rest of the samples.

Of the 18 *Y. pestis* isolates described above, 11 were recovered from the pneumonic patients and 7 from rodent specimens (Table 1). The age and sex of the patients yielding *Y. pestis* isolates are given in Table 2.

Figure 3. Growth of *Y. pestis* in broth tube.

Figure 4 *a, b*. Protein profiles of *Y. pestis* isolates using 10% SDS-PAGE.

Due to the limited amount of anti F1-FITC conjugate available, only 4 of the *Y. pestis* isolates (nos. 1, 2, 3 and 4) could be tested. All the four showed the presence of F1 antigen by fluorescent antibody test (Figure 5).

SPECIAL SECTION: THE PLAGUE EPIDEMIC OF 1994

Table 1. Summary of bacteriological (*Y. pestis*) isolation and identification experiments carried out on samples from Surat city and Beed district

Sample collection			Number processed	Number positive

11	22.09.94	18	M

17 of the 18 isolates exhibited clear precipitin bands against rabbit anti F1-antibodies. Isolate no. 12 did not show the presence of F1 antigen by this test. Similarly other non *Y. pestis* organisms including the *Y. pseudotuberculosis* and *Y. enterocolitica* were negative.

Discussion

Confirmation of a plague outbreak is achieved chiefly by isolation of *Y. pestis* or by demonstrating the serological responses compatible with the infection. In the present suspected outbreaks in Maharashtra and Gujarat states, the isolation work described here was undertaken after the Technical Advisory Committee was established and after the outbreaks had abated. The samples were collected by our collaborating institutions from patients in Surat at the time of the outbreak. There was a gap of over 45 days from collection to processing of samples from Surat patients. This could have been the main reason for finding mixed growth of organisms in all the 82 samples that were processed and for colonies resembling *Y. pestis* that could be purified only from 11 of these samples. Tissue specimens from 7 out of 132 rodents collected during and after the outbreaks and tested 10 to 30 days after field collection yielded *Y. pestis* organisms following purification from the mixed growth. Although *Y. pestis* grows easily on most of the bacteriological media, the growth is relatively slow. Problems are encountered in differentiating *Y. pestis* when other organisms are also present in the samples. Contaminating organisms are nearly always present in sputum samples and in most of the animal and flea specimens submitted from the field. Cultures showing mixed flora (including *Y. pestis*) on solid or broth media require the microbiologist to proceed promptly within 2-4 days to separate and identify *Y. pestis*. Otherwise, most contaminating organisms by virtue of more rapid growth become so predominant that it becomes difficult to obtain separate colonies of *Y. pestis*. Eventually the contaminants outgrow *Y. pestis* in the culture, making it impossible to confirm the latter's presence⁶. The long gap in processing of specimens from the time of collection is probably responsible for the smaller number of isolates from the Surat patients.

A striking observation was that 9 of the 11 patients from whom the *Y. pestis* was isolated were admitted to

the hospital on 22 September 1994. In accordance with the epidemiological information available, the outbreak in Surat affected mainly young adults and started on 19 September 1994. The clinical diagnosis of suspected pneumonic plague was made on 21 September 1994. Since at that stage therapy with antibiotics appropriate for plague had just been initiated, this could have contributed to a certain extent in the recovery of more isolates from these early cases. The maximum number of isolations (9) were from male patients in the young age group of 9 to 34 years.

It has been stated that positive results obtained by Gram, Giemsa or Wayson staining of smears to identify safety-pin appearance of *Y. pestis* and the F1-FAT test are not confirmatory for plague but are vital preliminary steps in making the diagnosis^{7,8}. In our study, Gram and Wayson staining for safety-pin appearance was quite confusing even to arrive at a presumptive diagnosis. The F1-FAT was not done directly on clinical samples from the present outbreaks because of a scarcity of the necessary reagents.

Biochemical characterization using the above-mentioned biochemical tests was not conclusive to establish a firm identity. Four of 22 isolates which biochemically resembled *Y. pestis* turned out to be different organisms when SDS-PAGE technique for protein profiles was undertaken. These were also not lysed by specific bacteriophage.

Among the rodent isolates, 3 were from affected areas in district Beed from specimens collected within a period of 3 months after the outbreak. The remaining 3 from the same areas were recovered within a period of 9 months to one year after the outbreak. One among these was from *Tatera indica*, the pericommensal rodent, trapped within one kilometer radius of Mamla village with a flea index of 5.5. The lone Surat rodent isolate was from Ved Road locality, the most affected area during the outbreak in 1994. These rodent isolations are a pointer to the fact that the plague foci are still active in the two affected areas.

Earlier studies⁹ have shown that *Rattus rattus* and *Rattus exulans* are susceptible commensal rodent species. In the present instance, 6 of the 7 rodent isolates were from trapped *Rattus rattus* specimens. Probably the *Y. pestis* infection in these animals did not reach the stage of being fatal or the infecting organisms are less virulent or may be the *Rattus rattus* in these areas are becoming relatively resistant. The presence of F1 capsular antigen, a virulent marker, was, however, demonstrated in 6 of the 7 isolates by CIE and the existence of 70 kb plasmid was confirmed in all the isolates.

It is well known that once plague becomes endemic in foci in a country, it is very difficult to eliminate it because the rodent reservoirs of these organisms cannot be eliminated. Regular monitoring of rodent populations and routine testing of suspected patients should form important components in plague surveillance systems. Awareness of the fact that apart from bubonic or pneumonic appearances, gastrointestinal symptoms have been frequently recorded as primary clinical manifestations of confirmed *Y. pestis* infection¹⁰ requires the clinicians to be extra cautious. Abdominal pain may be attributed to intra-abdominal buboes, which can occur without inguinal lymph node involvement⁷. In a recent case study report, confirmed plague presented itself as upper respiratory tract infection, nonspecific febrile syndrome, gastrointestinal or urinary tract infections and meningitis¹¹. Therefore, for the differential diagnosis of such syndromes, a reliable diagnosis of plague is essential.

ACKNOWLEDGEMENTS. We are obliged to Prof. V. Ramalingaswami, Chairman and Dr T. Verghese, Member Secretary, Technical Advisory Committee on Plague, Govt. of India for giving us the opportunity to carry out this work and for constant encouragement. We are also thankful to Dr R. V. Swamy, Director and Shri K. M. Rao, Joint Director, DRDE, Gwalior for providing all the necessary facilities and support to undertake this study. Our thanks are also due to Dr K. K. Datta, Director, NICD and Dr Gautam Biswas, Dr A. K. Khera, Dr Shyamal Biswas, Shri Sohan Lal and Dr U. V. S. Rana, scientists at NICD; Dr Pratima Patel, Head of Microbiology Division and Shri H. P. Pandya, of Surat Medical College, Surat for providing human and rodent samples on behalf of the Technical Advisory Committee. We thankfully acknowledge the support provided by Dr May C. Chu, WHO Collaborating Center at CDC, Fort Collins, USA.

Passive haemagglutination tests for *Y. pestis* infection in Surat pneumonic patients

G. S. Agarwal and H. V. Batra

Defence Research and Development Establishment, Jhansi Road, Gwalior 474 002, India

Passive haemagglutination tests, utilizing a highly purified, specific Fraction 1 antigen of *Yersinia pestis* have been employed to detect antibodies in the sera of pneumonic patients of Surat city. The high antibody titres observed in a majority of sera samples (85.2%) from convalescent patients 2 to 3 months following the outbreak are indicative of *Y. pestis* infection.

SEROLOGICAL responses against the *Y. pestis*-specific Fraction 1 (F1) antigen have been successfully employed for detection of plague in serosurveillance studies. Even at the time of outbreaks, serological tests have their merits in providing confirmatory evidences of plague infection particularly so when the bacterial isolations have been neglected. Passive haemagglutination/passive haemagglutination inhibition tests (PHA/PHAI) and complement fixation test employing the highly purified, specific Fraction-1 antigen of *Y. pestis* are commonly used to detect antibodies in plague¹⁻³. Plate- and dot-enzyme linked immunosorbent assays (ELISAs) for detection of antibodies to F1 and a monoclonal antibody based ELISA for F1 antigen detection have been described⁴⁻⁶. The WHO recommended tests are PHA and PHAI and these are reported to have a high degree of specificity and sensitivity for detection of anti F1 antibodies⁷.

The serum samples from human patients, rodents and other animals following suspected bubonic plague in district Beed and suspected pneumonic plague outbreaks in Surat city were tested at various intervals by several institutions namely, the National Institute of Communicable Diseases (NICD), The National Institute of Virology (NIV) and WHO. The present work reports the antibody test results on serum samples collected from convalescent patients from the outbreak-affected areas.

Materials and methods

Serum samples

A batch of 27 convalescent serum samples from patients with suspected pneumonic plague from Surat were collected in the last week of December, 1994, two to three months after the outbreak. Another batch of 102 serum

samples were collected from Surat city during the month of March, 1995.

Eighteen serum samples collected from Beed district of Maharashtra in the month of April, 1995 and 13 serum samples during July, 1995 were also tested. These human serum samples were from the general population of that area.

A group of 55 human serum samples of pyrexia cases (pyrexia of unknown origin, PUO) negative for typhoid and malaria infections collected prior to the suspected plague outbreaks from a non-affected area were also tested simultaneously.

PHA and PHAI tests

The sera were examined for antibody to the F1 antigen using the PHA and PHAI microtitration procedures recommended by WHO for the serodiagnosis of plague^{8,9}. Briefly, serum samples were heat inactivated at 56°C for 30 minutes and then 50 µl of packed, washed sheep red blood cells (SRBC) added to every 0.5 ml of test serum. They were adsorbed for 60 minutes at room temperature and then centrifuged at 1500 rpm for 10 minutes. For PHA test, 25 µl of PHA diluent (1% normal rabbit serum in normal saline) was added to all wells of 'U'-shaped microtitration plates. For PHAI test, the diluent used had 0.2 mg/ml F1 antigen in PHA diluent. In the next step, 25 µl of test serum was added to the first well of microtitration plate and serially diluted. A volume of 25 µl of appropriately diluted F1 sensitized SRBC was added to all the wells. Plates were covered and incubated at room temperature for 6 h and then overnight at 4°C.

Results

The wells were examined for flocculent, lattice agglutination. Negative wells showed a sharp-edged button or a defined circle. End-point titres were determined by taking the last well showing complete agglutination. Final titres were determined by subtracting PHAI titres from PHA titres of individual sera samples. Among the first batch of 27 samples from suspected convalescent plague patients from Surat, 23 showed titres of 1:16 or more

Table 1. PHA and PHAI titres of tested human sera samples

Place	Period of collection	Total tested	Number with titres								Total positive (%)
			Nil	1:4	1:8	1:16	1:32	1:64	1:128	1:256	
Surat	Dec. '94	27	—	—	4	2	12	7	2	—	23 (85.2)
Surat	March '95	102	77	6	10	2	3	2	1	1	9 (08.8)
Beed	April '95	18	12	3	3	—	—	—	—	—	—
Beed	July '95	13	11	1	1	—	—	—	—	—	—
Gwalior	July '94	55	52	—	1	1	1	—	—	—	2 (03.6)

(Table 1). Of the 102 sera samples collected from Surat in the second batch, only 9 showed positive titres. Human serum samples collected 8 to 11 months after the outbreak in district Beed were found to be negative.

Two of the 55 sera samples of PUO cases from non-affected area were also positive with titres of 1:16 and 1:32, respectively.

Discussion

Confirmation of a clinical diagnosis of plague is based chiefly on isolation of *Y. pestis* and/or demonstration of four-fold rise of antibody titres at paired sera testing. It is well established that *Y. pestis* antibody is more readily detected than isolation and identification of *Y. pestis*.

Confirmation of plague by serology, particularly in pneumonic cases, is retrospective to the outcome for the patient as most fatalities occur within a week of infection, whereas, antibodies generally appear in significant titres about one to two weeks following the infection. Therefore, antibody detection from patients during the period of acute illness is of limited value. Serology on convalescent patients, two weeks to few months after infection is more suggestive of plague occurrence. A serologic titre of 1:10 or more in the absence of known recent plague vaccine history is considered positive for plague antibodies. A four-fold rise in titre between two time distanced samples (greater than two weeks apart) is considered confirmatory⁸. Since acute phase serum samples collected during the outbreak were not available for testing, it was not possible to analyse results of paired sera testing. Serological results on blood samples collected from convalescent patients 2–3 months following the pneumonic outbreak were, therefore, analysed independently. A majority of cases (23 out of 27) showed high levels of positive titres (>1:16 to >1:256). Such a large proportion of convalescent cases showing positive PHA and PHAI titres against specific F1 antigen of *Y. pestis* is highly suggestive of plague in pneumonic patients of Surat city. Only two of the 55 sera samples from the non-affected area had positive titres. Detection of these two positive cases from among the PUO cases from the non-affected area and that too, prior

to the appearance of the outbreak is enigmatic. Could it be due to the presence of *Y. pestis* infection in an inapparent form in that region or a cross-reactivity with other disease-causing agents? This question needs further study.

Serum samples collected 5–6 months after the outbreak showed a low percentage of positive titres. A progressively decreasing number of positive serological reactions within a period of several months is indicative of effective control of the outbreak⁷.

Human serum samples from district Beed were all found negative for antibodies to F1 antigen. Since the sample collection from the individuals was after 8–11 months of suspected plague outbreak in that area, probably the antibody titres by this time had disappeared. Moreover, these samples were from general population and more likely to be the contact individuals rather than the patients who suffered with suspected bubonic plague illness.

PCR analysis of formalin-fixed human autopsy tissues, rodent tissues, fleas and bacterial isolates from pneumonic patients from the 1994 plague epidemic confirmed the presence of the *f1* and *pla* genes of *Yersinia pestis* in these samples. Several *Y. pestis* isolates from the epidemic areas were studied in respect of their plasmid profile, expression of F1 antigen and ribotype pattern. All the three plasmids known to be associated with virulence were present in the Surat isolates of *Y. pestis*. Presence of the F1 antigen, classically used for diagnosis of *Y. pestis* infection, was demonstrated by immunoblotting. All the Indian isolates from the 1994 epidemic showed an identical ribotype profile. This profile, however, was different from those of *Y. pestis* isolates tested from other regions of the world.

Upon digestion with *EcoRI* and *EcoRV*, and probing with *E. coli* 16S and 23S rRNA genes, DNA from these *Y. pestis* isolates gave two distinct profiles which, taken together, suggest that the present Indian isolates represent a new ribotype. The presence of *Y. pestis* signature genes in 5 out of 7 fleas collected from rodents in the affected areas, and the occurrence of the same ribotype in the *Y. pestis* isolates from domestic rodents, sylvatic rodents and the patients are strongly indicative of a clonal origin of this Indian strain and an epidemiological linkage among wild rodents, domestic rats and humans in the epidemic area.

IN August 1994 the village Mamla in Beed district of Maharashtra state experienced an unusually heavy flea nuisance and rat falls. Subsequently, a number of cases clinically resembling bubonic plague were reported from Mamla and nearby villages of Beed district. Based on the totality of ecological, clinical and serological

evidence, a presumptive diagnosis of bubonic plague was made and the health machinery of the State Government, with the active support of the Central Government, took prompt measures and the epidemic was successfully contained.

In September 1994, Government hospitals and private clinics in the city of Surat in the neighbouring state of Gujarat reported an increasing number of patients with an illness resembling acute pneumonia. Based on clinical, laboratory and radiological findings, a presumptive diagnosis of an outbreak of pneumonic plague was made.

Plague is an acute zoonotic bacterial disease caused by infection with *Yersinia pestis*. *Yersinia* belongs to a group of bacterial pathogens of the family Enterobacteriaceae. Three members of this group, *Yersinia pseudotuberculosis*, *Yersinia enterocolitica* and *Yersinia pestis*, are human pathogens. These species carry one or more plasmids of molecular weights 110 kb, 70 kb and 9.5 kb which have proved to be of diagnostic value. Only *Yersinia pestis* carries all the three plasmids^{1,2}.

The pathogenicity in *Y. pestis* is multifactorial, with the genes responsible being present on the chromosome as well as on all the three plasmids. The 9.5 kb plasmid is unique to *Y. pestis* and is not present in the other two *Yersinia* species. This plasmid carries the *pla* gene which codes for a virulence factor called plasminogen activator. The complete sequence of this 1041 nucleotide-long gene is known³. Although *pla* has partial sequence homology to the '*omp*'-T gene of *E. coli* and gene '*e*' of *Salmonella typhimurium*, there are unique regions which can be used for amplification of the *pla* gene by PCR for identification of *Y. pestis* isolates⁴ and plague surveillance⁵. The two other plasmids, 110 kb and 70 kb, produce specific products like Fra I and

Yersinia Yops protein. The *Fra1* protein, encoded by *fl* on the 110 kb plasmid, is unique to *Y. pestis* and has been classically utilized for diagnosis of *Y. pestis* infection. This gene is highly conserved amongst various isolates of *Y. pestis* and thus provides the characteristic 'signature' for *Y. pestis*.

The present report describes results which demonstrate the presence of *Y. pestis* genes in human tissue samples collected at autopsies in Surat. The same signature sequences were demonstrated in fleas collected from rodents trapped during the epidemic in Beed. Molecular characterization of *Y. pestis* isolates from Beed and Surat is also described.

Materials and methods

Bacterial cultures. The bacterial isolates (Table 1) were grown from single colonies in nutrient broth for 24 hours. The cells were pelleted, resuspended in 70% ethanol and stored at -20°C until further use.

Formalin-fixed human tissues. Tissue samples from lungs and spleen were collected at autopsy from deceased persons and stored in 10% buffered formalin. All patients were from Surat with pre-mortem diagnosis of pneumonic plague.

Fleas. Fleas were collected from the epidemic areas in Beed district and stored in 70% ethanol.

Polymerase chain reaction

Primers. The primers used for PCR are listed in Table 2. These were synthesized on an automated oligonucleotide

Table 2. Sequences of oligonucleotide primers used in this study

For the plasminogen activator gene:

YP1-5' ATCTTACTTTCCGTGAGAAG 3'
 YP2-5' CTTGGATGTTGAGCTTCCTA 3'
 YP3-5' ATACTGTGACGGCGGGTCTG 3'

 FI-3845' CATCCCCACAAGGTTCTCA 3'

synthesizer (Applied Biosystems, USA; Model 392) using phosphoramidite chemistry.

DNA preparation. The bacterial cells stored in 70% ethanol were centrifuged at 10,000 rpm for 5 minutes. The supernatant was discarded, the pellet was air dried and resuspended in 100 µl of sterile distilled water. The samples were boiled for 10 minutes and rapidly chilled on ice. The boiled material was centrifuged at 10,000 rpm for 5 minutes and the supernatant was used as template for PCR.

Approximately 10 mg of tissue was sliced from each of the formalin-stored samples and washed thrice with 0.05 M tris-HCl (pH 7.5). The material was ground in 50 mM tris-HCl (pH 8.0), 50 mM KCl, 2.5 mM MgCl₂, 0.45% Tween-20, 0.45% NP-40, using a glass rod. Proteinase K digestion was carried out overnight at 55°C in 500 µl of buffer (10 mM tris-HCl, 5 mM EDTA and 0.5% SDS) containing proteinase K (100 µg/ml). The samples were then extracted with hot phenol for 2 hours at 65°C. After chloroform extraction, the supernatant was precipitated at -70°C with 0.3 M sodium acetate and two volumes of ethanol. The extracted DNA was

SPECIAL SECTION: THE PLAGUE EPIDEMIC OF 1994

pelleted and washed twice with 70% ethanol. The pellet was air-dried and reconstituted in 25 µl sterile distilled water. The samples were denatured for 5 min in boiling water and then chilled in ice.

Ethanol was drained from the flea samples which were then air dried. DNA was extracted by the hot phenol method as described.

Both positive and negative controls were included and all possible precautions were taken to avoid contamination.

Amplification of DNA by PCR. For amplification of the *pla* gene, PCR was carried out in 100 µl reaction volumes with 50 pmol each of external primers (Table 2), 1X Taq buffer, 3 mM MgCl₂, 400 µM dNTPs, 2.5 units of Taq DNA polymerase (Stratagene) and 1/10th volume of template DNA. The reactions were carried out by programming the DNA thermocycler (Technique, UK) at 95°C for 5 min, 52°C for 1 min and 73°C for 1 min for 1 cycle followed by 2 cycles at 95°C for 2 min, 52°C for 1.3 min and 73°C for 1.3 min; 35 cycles at 95°C for 1 min, 51°C for 1 min and 73°C for 1.3 min. One tenth volume of the first PCR product was reamplified with internal primers using the same conditions. For amplification of *f1*, the reactions were set up as above except that 1.5 mM MgCl₂ was used. The reactions were carried out at 95°C for 5 min followed by 35 cycles at 95°C for 1 min, 51°C for 1 min and 72°C for 2 min.

Ribotyping

Bacterial cells were grown in nutrient peptone broth from single colonies for 48 h. The cells were pelleted and chromosomal DNA was extracted using SDS-Proteinase K digestion followed by phenol-chloroform extraction. DNA samples (2.5 µg each) were digested with *EcoRI* or *EcoRV* restriction enzymes (Promega, USA) for 4 h at 37°C according to manufacturer's instructions. Electrophoresis was carried out on 0.8% agarose gel in 1X TBE buffer (90 mM Tris, 9 mM boric acid, 2 mM EDTA, pH 8.0) overnight. Southern hybridization was performed using Hybond membranes (Amersham, England) essentially according to the manufacturer's instructions. Fragments carrying the 16S, 23S and 5S *E. coli* rRNA genes⁶, from plasmids pKK 3535/pL215 were used as probes. In addition, 16S and 23S ribosomal RNAs were purified from *E. coli* and used as probes. The probes were ³²P-labelled by nick translation or by 5' end labelling. PCR ribotyping was carried out using primers from the conserved regions of the 16S rRNA gene.

Plasmid analysis by pulsed field gel electrophoresis (PFGE)

The bacterial cultures were grown overnight in BHI broth from single colonies. Cells from 1.5 ml of culture

were pelleted and the plasmids isolated using commercially available kits (Wizard, Promega, USA). Purified plasmids were suspended in 100 µl of Tris-EDTA buffer (pH 8.0) and mixed with an equal volume of 2% low-melting agarose. The plugs were prepared in Biorad moulds and subjected to PFGE in 1% agarose in 0.5X TBE buffer for 21 hours at 18°C. Lambda oligomers were used as size markers. The plasmids were visualized after staining with ethidium bromide.

Protein profile studies using sodium dodecyl sulphate polyacrylamide gel electrophoresis (SDS-PAGE)

Bacterial cells were grown overnight on BHI agar from single colonies. A loopful of cells was suspended in PBS, washed thrice in the same buffer and pelleted. The pellets were resuspended in 50 µl distilled water and 50 µl SDS-PAGE loading dye. The samples were boiled for 4 minutes at 100°C and run in a 10% polyacrylamide gel at 40 mA until the dye front was close to the bottom of the gel. The protein bands were visualized by staining with Coomassie blue using standard protocols.

Immunoblot analysis for F1 antigen expression

The bacterial cell lysates were subjected to electrophoresis in 10% SDS-PAGE as above and the proteins were transferred onto nitrocellulose membranes (S&S, Germany), at 100 mA for 1 hour. The membranes were blocked with 3% BSA overnight and incubated with rabbit anti-F1 antibodies at a dilution of 1:20,000 for 1 hour. The F1 antigen was detected with alkaline phosphatase-conjugated anti-rabbit IgG (1:6,000 dilution) for 1 hour. It was then developed with phosphatase substrate for 4–5 minutes.

All experiments reported here were performed independently in more than one laboratory.

Results

Conditions for PCR amplification of the *pla* and *f1* genes were standardized. DNA samples isolated from a number of bacteria pathogenic to humans, but known to lack the *pla* and *f1* genes, were used as controls in the PCR experiments. DNA samples from the 18 *Y. pestis* isolates from the epidemic areas (Table 1) showed the presence of both the *pla* and *f1* genes. Of the 7 autopsy tissue samples, 3 were positive for the *pla* gene (Table 3) and 5 were positive for the *f1* gene (Figure 2 and Table 3). Five of the 7 flea samples (C1, C2, C3, ANJ4

Figure 3. Southern hybridization of *EcoRI*- and *EcoRV*-digested *Y. pestis* chromosomal DNA. ³²P-labelled *E. coli* 16 S and 23 S rDNAs derived from pKK3535 were used as probes. Panel A indicates *EcoRI* digests and Panel B, *EcoRV* digests. Names of *Y. pestis* strains tested are indicated at the top. Patterns for only a few Indian isolates are shown. None of the Indian isolates (Ind 101, 103 and 104) has a profile similar to any other *Y. pestis* strains tested.

and ANJ6) collected from Beed during the epidemic period were positive for the *f1* gene (data not shown). The amplified products were cloned and sequenced and the identity of the genes confirmed. The *pla* and *f1* genes did not amplify in any of the control samples.

For ribotyping of the *Y. pestis* isolates from Surat and Beed, restriction endonucleases *EcoRI* and *EcoRV*, which are known to be the most discriminatory⁷, were used. A few strains isolated from different parts of the world and already ribotyped at the WHO *Yersinia*

Figure 4. Western blot analysis of *Y. pestis* isolate no. India-9 (from Surat) in comparison with the other older Indian isolates and controls showing expression of F1 antigen of ~19 kDa.

Reference Centre, Pasteur Institute, Paris, were included in this study.

EcoRI ribotype profiles displayed by the Indian isolates were identical to one another and were similar to those displayed by strains EXV 796, Nhatrang, Madagascar and Turkey 10.1 but differed from those displayed by strains PKR VI, PKR XXIV, Belgian Congo, PKH IV and Kenya 162 (Figure 3). When an identical set of experiments was performed with the restriction endonuclease *EcoRV*, it was observed that, again, all Indian isolates had the same ribotype profile (Figure 3). Unlike the *EcoRI* case, however, this profile differed markedly from the profiles displayed by EXV 796, Nhatrang, Madagascar and Turkey 10.1 but were similar to those displayed by PKR VI, PKR XXIV, Belgian Congo and PKH IV (Figure 3). Of particular interest is the fact that when both *EcoRI* and *EcoRV* ribotype profiles are considered together, the Indian isolates had profiles distinct from those of the foreign isolates, (Figure 3). This combination of *EcoRI* and *EcoRV* patterns seen in the present Indian isolates has not been seen in any of the *Y. pestis* strains examined earlier (Guiyoule *et al.*⁷ and personal communication⁸). Thus, the ribotype observed in this study constitutes a new ribotype, named 'S' for Surat by the WHO *Yersinia* Reference Centre, Pasteur Institute, Paris. All the present Indian isolates were found to belong to this ribotype. Similar ribotype patterns were obtained irrespective of the type of probe used. Upon PCR amplification of the 16S rRNA gene, products of identical size were obtained from all isolates originating from Beed and Surat.

Pulsed field gel electrophoresis carried out on three isolates (4, 8, 9) demonstrated the presence of all the three plasmids.

In SDS-PAGE, the overall migration pattern of the proteins was similar in all the Indian isolates. A protein band of approximately 25 kDa was observed in the Surat isolates 4, 8 and 9 at the WHO Reference Centre, CDC, Fort Collins, USA. However, our own attempts to reproduce this result were unsuccessful (see Discussion below).

The F1 antigen was detected in all the isolates by immunoblot assay, indicating that the isolates were pathogenic (Figure 4 shows results for isolate-9).

Discussion

After the outbreaks in Beed and Surat, it was obviously necessary to identify and characterize the causative organism. This was achieved by PCR analysis of autopsy tissues from 7 individuals using primers for the *Y. pestis*-specific *pla* and *f1* genes. Five out of the 7 individuals whose autopsy tissues were analysed were positive for the *f1* gene and three were also positive for *pla*, providing unequivocal evidence of the involvement of *Y. pestis* in these deaths. It is worth mentioning that this is perhaps the first time that such *in situ* demonstration of *Y. pestis* in historical material had been attempted. By PCR analysis, eighteen bacteriologically characterized *Y. pestis* isolates were shown to be positive for the *Y. pestis* *pla* and *f1* genes (Table 1). Eleven of these isolates were from pneumonic plague patients from Surat city and seven were from rodents collected from the

epidemic areas during the period August 1994 to August 1995.

Numerous reports have shown that ribotyping is an extremely useful tool for the molecular characterization of bacterial species. To differentiate strains belonging to the same species by ribotyping, it is essential to choose restriction endonucleases which are most discriminatory. Guiyoule *et al.*⁷ have demonstrated that for the analysis of *Y. pestis* strains, restriction endonucleases *EcoRI* and *EcoRV* are particularly useful. *Y. pestis* strains isolated from Surat and Beed (including those isolated from trapped rodents) showed the same ribotype profile. Further, this profile (i.e. *EcoRI* and *EcoRV* patterns considered together) differed from those obtained with all other isolates examined so far (Guiyoule *et al.*⁷ and personal communication⁸), justifying the conclusion that these Indian strains are clonal in origin. Among the rodent isolates studied, one was from a *Tatera indica* specimen, a sylvatic species, and six were from *Rattus rattus*, a domestic species. The ribotype profile observed in the bacterial isolates from these domestic and sylvatic rodents was the same as that observed in the isolates from the patients. This is strongly supportive of an epidemiological linkage among wild rodents, domestic rats and humans in the epidemic area. The observation that five out of the seven flea samples collected from trapped rodents in the affected area also showed the presence of *Y. pestis* signature genes is in support of such an epidemiological connection.

The 85 *Y. pestis* strains examined by Guiyoule *et al.*⁷ have been classified into 16 ribotypes⁷. Even though the ribotype of the Surat strain is distinct from the 16 previously known ribotypes, it does not necessarily mean that it defines a strain of recent origin. This is because, as mentioned above, ribotyping has been done on only 85 out of the approximately 6000 strains known to exist in *Y. pestis* collections worldwide. Therefore, it is entirely possible that among the remaining 5900 or so strains, the Surat ribotype could be present in one or more strains. This can be only ascertained by further investigation.

Even though one of the worst pandemics in history occurred in India, and about 12 million people died between 1896 and 1930, only a few strains from these years have survived in various culture collections, mostly outside India. Considering that the only isolate ribotyped from India was collected in 1908 and that very few other Indian isolates are available over the last 100 years, it is not possible to say whether the Surat strain is of recent origin. This is because of our ignorance of the ribotype characteristics of the large number of strains that must have existed in the country during the past 90 or so years.

Studies carried out by the Pasteur Institute, Paris on *Y. pestis* isolates from Madagascar indicate the presence of more than one ribotype in this small island country (E. Carniel, personal communication). Moreover, there is a specific geographical distribution of these variants on

the island. Drug-resistant strains of *Y. pestis* have reportedly arisen recently in this endemic area.

The presence of all the three plasmids characteristic of *Y. pestis* in the Surat isolates was confirmed by pulsed field gel electrophoresis. This observation suggests that the Surat strain is different from the Russian vaccine strain EV because the latter lacks one of the three plasmids.

Upon single dimension SDS-PAGE, the protein profiles of the different *Y. pestis* strains studied by us showed an overall similarity. However, in Surat strains 4, 8 and 9, an additional 25 kd protein band was observed in experiments done at the WHO Reference Center, CDC, Fort Collins, USA. This band was not detected in subsequent studies done by us on the same isolates. This is perhaps not surprising in view of the fact that protein profiles obtained by single dimension SDS-PAGE can produce non-identical patterns depending upon the culture conditions, degradation of high molecular weight proteins and other variables. Even in case of *Y. pestis* it has been observed that though there is an overall similarity in the protein profiles produced by different strains, several display one or more unique bands.

The presence of the F1 antigen, which is routinely used for serodiagnosis of *Y. pestis*, was demonstrated in Surat isolates by immunoblotting, confirming that these isolates were indeed *Y. pestis*.

In conclusion, these results (i) confirm the association of *Y. pestis* with the epidemic at Surat and Beed; (ii) demonstrate that the *Y. pestis* isolates obtained from these regions were identical, indicating that the pathogen was most likely clonal in origin; and (iii) suggest that the pathogen has had an enzootic existence in the region. Further epidemiological studies, as well as collection and characterization of *Y. pestis* isolates from different parts of the Indian subcontinent, are necessary for a better understanding of the dynamics of this important pathogen.

ACKNOWLEDGEMENT. We appreciate the help provided by the three WHO Reference Centres for *Yersinia* at Stavropol, Russia, Pasteur Institute, Paris and CDC, Fort Collins, USA. AG and CS thank Dr Sangeeta Pajni for her help in one of the experiments and Dr C. M. Gupta, Director, IMTECH for his support. HSC's participation in this work was aided in part by grants from ICMR, New Delhi and the JNCASR, Bangalore.

Ecology of flea-transmitted zoonotic infection in village Mamla, District Beed

Vijay K. Saxena and T. Verghese*

National Institute of Communicable Diseases, 22, Shamnath Marg, Delhi 110 054, India

*Directorate General of Health Services, Nirman Bhavan, New Delhi, India

Ecological observations were made in the village Mamla and the area around it in Beed district to (i) gather evidence on ecological support system for natural harbourage of rodent species in domestic, peridomestic and feral situations, and (ii) enumerate ecological factors and situations which may have triggered the 1994 outbreak.

Prior to the Maharashtra earthquake of 1993, the ecosystem of Mamla maintained equilibrium densities of domestic rodent (*Rattus rattus*) and their fleas (*Xenopsylla cheopis*). This prevented fulminating epizootics among domestic rats. However, the impact of the September 1993 earthquake in Maharashtra introduced major changes in human ecology at Mamla village which generated unlimited energy inputs (such as foodgrains) for domestic rodents. As a result, there was a gradual, but persistent, growth of *R. rattus* population in the subsequent 8–10 months quiescent period. In August 1994, the *R. rattus* population overshot its equilibrium density level, which eventually led to a flea-mediated epizootic in rats and an outbreak of a cryptozootic, possibly plague, infection in humans in Mamla.

FLEAS as ectoparasites of rodents are known to be the vectors of human diseases like plague, murine typhus and tularemia. Among the 76 species of fleas recorded from the Indian subcontinent¹, the roles of only 3 species viz. *Xenopsylla astia*, *X. brasiliensis* and *X. cheopis* are well known in plague transmission. However, evidence also exists on the involvement of these flea species in the transmission of murine typhus (*Rickettsia typhi*), which is widespread even in rural India where climatic conditions favour survival of rats and their ectoparasites; however the disease is grossly under-reported^{2,3}. These rodent–flea borne infections may remain in enzootic form with rare or accidental human transmission depending upon the extent of man–flea contact. Local ecological factors play a key role in the ectoparasite-mediated spill-over of infection from rodent to man.

During August 1994, the inhabitants of village Mamla in Beed district of Maharashtra State, experienced heavy flea nuisance. Subsequently, a number of cases clinically resembling bubonic plague were reported from the village⁴. During May 1995, field investigations were

undertaken in and around village Mamla to (i) examine the ecological support system (ESS) for the natural harbourage of rodents in and around the village and (ii) elucidate ecological conditions which may have triggered flea-borne epizootic infection among rodents and its spill-over to humans.

Extensive geographical reconnaissance was undertaken within 30 km around the village Mamla to obtain information on terrain, soil types, vegetation and cropping pattern in agricultural fields. Meteorological data were obtained from the Meteorology Department at Pune.

Wonder traps were laid in the village in the evening and picked up the next morning. Rats were retrieved from the traps and fleas were combed out of their body. Blood was drawn directly from the heart to collect serum for serology. Later, these animals were dissected to take out their lung, liver and spleen and these organs were transported in Cary Blair medium for isolation of bacilli at the Defence Research Laboratory, Gwalior.

Beed district falls along the dry-deciduous scrub land zone of Deccan Lavas region of north-western peninsular plateau. It has small-sized sparse trees mainly *Acacia* sp., with scattered thorny shrubs. The narrow stretches of grasslands used as pastures generally remain dry and barren from March to June.

The village Mamla is an old, remote village, 32 km away from Beed town and falls under Primary Health Centre at Kuppa. The village has a small population of about 350 people, who are mainly agrarian by occupation. During September 1993 a major earthquake shook the adjoining districts of Osmanabad and Latur, but mild tremors were also experienced in certain parts of Beed district. Consequently the residents of Mamla village abandoned their permanent homes in fear during October 1993 and resettled in temporary tin shelters erected on the southern and western borders of the village (Figure 1). The fear of recurrence of earthquake prevented the villagers from reoccupying their old permanent houses which were being used exclusively for storing food grains (wheat, groundnut, millet, etc.). The villagers occasionally visited these houses, for procuring the stored foodgrains.

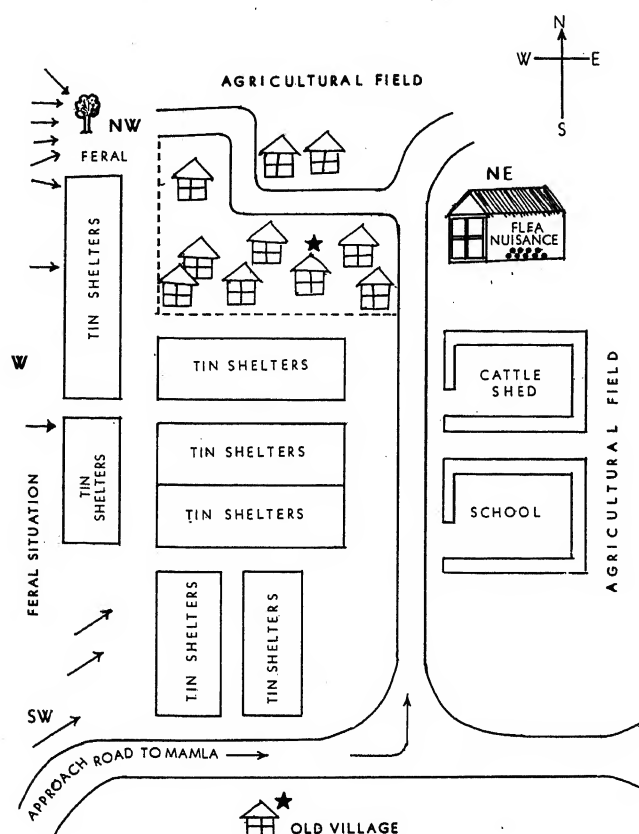

Figure 1. Schematic presentation of village Mamla, Beed.

The village is surrounded on 3 sides, i.e. north, east and south by agricultural fields (agro-climatic zone). However, its western border is contiguous with a small pocket of feral land in the north (Figure 1). The three adjoining borders in the north, east and south of Mamla are cultivated areas, classifiable as a peridomestic agroclimatic zone. The agricultural fields in this zone mainly produce wheat, millet, sugarcane and groundnut. Burrows of the field rodent *Bandicota bengalensis* were found in these agricultural fields mainly in fallow wheat field and a few in the bunds bordering the fields. *B. bengalensis* infestation in the area was relatively poor, though there were some in the fields.

The village has cattle, goat and buffalo populations of about 40, 35 and 18 respectively. Goats are taken every day to open pastures about 1–2 km away for grazing.

The landscape, as observed between Beed city and Mamla village, is a plain and undulating open terrain. The soil is mainly black cotton soil, interspersed with reddish-brown and sandy loose alkaline soil. The black and brown loose soils are mainly used for agriculture but some of the feral areas generally have loose sandy or light red gravelly type of soil. The small discontinuous feral pockets are inhabited by *Tatera indica*.

Dry area crops like millet, cotton, groundnut, maize and wheat are the predominant crops, but in some areas with irrigation facilities sugarcane is also grown.

The maximum temperature during summer touches 44°C in May and the minimum falls to a low of about 5°C in January. However, the monthly mean maximum temperature varies from 29°C to 42°C and the monthly mean minimum temperature varies from 12°C to 25°C. The mean minimum temperature from April to September oscillates between 22°C and 26°C. Beed district is a relatively low rainfall area. An appraisal of monthly rainfall data for the year 1991 indicated that during the monsoon season of 120 days (June to September) there was a total of 20 rainy days, varying from 3 to 9 rainy days per month.

In the domestic biotope of village Mamla, a total of 10 rodents (*Rattus rattus*) was trapped from the peripheral houses of the village and 11 fleas (*Xenopsylla cheopis*) were collected from their bodies. The rodent and parasite indices are as follows:

Trap positivity	16.6%
Flea infestation rate	60.0%
Flea index (<i>X. cheopis</i>)	1.1
Intensity of infestation	1.8

These rats were found to be distributed towards the periphery in the old village and tin shelters in the north, west and southern parts of the village. The central and eastern areas of the village had a sparse rat population.

Organs from 10 *R. rattus* specimens which were processed for *Y. pestis* isolation did not reveal presence of the microorganism and serological tests were also negative for antibodies against *Y. pestis*.

The ecological support system was found to be highly conducive for natural harbourage of *Rattus rattus* in the domestic biotope; *Tatera indica* in the peridomestic feral biotope and *Bandicota bengalensis* in the peridomestic agroclimatic zone.

The biotope association of village Mamla is of a primitive type⁵ wherein the domestic biotope has direct ecological linkages with both the agro-climatic zone and the feral biotope. Such biotope associations are highly favourable for spillover of rodent-borne flea-mediated infection (such as plague) from the wild (feral) directly into the domestic biotope as the (agro-climatic) barrier zone⁵⁻⁷ is absent between the feral and the domestic biotopes on the western border of Mamla. Another known route of spillover of zoonotic infection from wild to domestic situation which was observed in Mamla is by passive transportation of wild fleas (*Xenopsylla astia*) from pasture land (feral) to the domestic through grazing goats. Such passive transportation of fleas has been reported earlier from Karnataka⁶. From the observations in and around village Mamla and the history of earthquake in the area during 1993 and its impact on human

ecology and other associated ecological features of the village, 4 situations were discernible as far as the dynamics of flea-transmitted zoonotic infections was concerned.

Situation I	(Pre-1993 earthquake)
Situation II	(October 1993; impact of earthquake)
Situation III	(September 1993 – July 1994; quiescent period)
Situation IV	(5 August 1995 onwards; outbreak period).

From situation I standpoint, the biotope-associated ecological linkages of the village Mamla in respect of the rodent and flea populations reveal a state of ecological equilibrium that existed in the rodent–flea relationship during the pre-earthquake period. The natural regulation of host and parasite populations was under density-dependent control factors which presumably prevented the flea population from increasing beyond the level necessary to initiate an epizootic or create pestilence among humans. Density-independent factors like temperature and rainfall in Mamla are not generally inimical to the growth of *R. rattus* and its flea population, as is evident from the minimum and maximum temperature range of the area and poor precipitation.

In situation II, the impact of the September 1993 earthquake in Latur and Osmanabad districts was also noticeable in Mamla village where the inhabitants abandoned their homes in October, 1993, leaving behind large quantities of foodgrains in their homes. The residents shifted to temporary tin shelters thereafter.

In situation III (quiescent period), between October 1993 and July 1994 (for about 10 months), the abandoned homes had ample quantities of stored food grains, for consumption by rodents without human disturbance. This period therefore witnessed on exponential growth of rat populations supported by an abundance and easy accessibility of food in the abandoned homes. This silent period, which promoted unrestricted reproduction and growth of *R. rattus* and *X. cheopis* populations between October 1993 and July 1994 is thus a result of imbalance in ecological equilibria.

In situation IV (August 1994), due to unrestricted growth of *R. rattus* and its flea *X. cheopis* for the previous 10 months, an unusual flea nuisance was seen, having been first detected in one of the peripheral houses in

north-eastern corner of the village (Figure 1). It seems probable that the rat population growth which overshot its upper asymptote level sometimes in July–August, 1994 resulted in shortage of space and at this juncture density-dependent population controls, of which disease is a component, operated on the rat population, leading to a rodent epizootic, mediated by the flea *X. cheopis*. A large number of susceptible individuals in the rat population may have suffered mortality which forced their fleas to venture for alternate hosts, including man.

Post-earthquake assessment of Latur and Osmanabad districts revealed an increased vulnerability to vector-borne diseases, including ectoparasite–rodent borne infections in the area⁸. Temporarily vacant houses are also known to produce a sudden abundance of adult fleas upon the return of the tenants and their pets⁹, a situation analogous to what was discernible in village Mamla. Population explosion of a domestic rodent *Mus musculus* resulted in outbreaks of murine typhus among farmers¹⁰. In village Mamla, therefore, a succession of significant ecological events for about an year appears to have led to a flea-transmitted outbreak of a cryptozootic rodent-borne infection in humans, possibly plague.

ACKNOWLEDGEMENTS. This work was carried out at the instructions of Dr K. K. Datta, Director, NICD, Delhi, to whom one of us (VKS) is very grateful for providing the opportunity. We thank Prof. V. Ramalingaswami, Chairman of the Technical Advisory Committee on Plague, for the unique opportunity of investigating the Beed episode. Dr Gaekwad (Entomologist) from Maharashtra State accompanied the field team for assistance during these investigations. Thanks are also due to Mr. P. R. Mittal of NICD, Delhi.

Observations on urban ecology of Surat and bubonic plague transmission in the city

Vijay K. Saxena and T. Verghese*

National Institute of Communicable Diseases, 22, Sharnath Marg, Delhi 110 054, India

*Directorate General of Health Services, Nirman Bhavan, New Delhi, India

Observations were made on the urban ecology of Surat city to understand the ecological support system conducive for wild rodent epizootic and its spill-over to initiate human bubonic plague outbreak. The unprecedented flood situation prior to the Surat outbreak was also appraised from the standpoint of plague dynamics. No obvious evidence could be gathered relating to the ecological support system and ecological linkages between rodents from urban and feral habitats which could have led to the spill-over of sylvatic rodent plague to initiate bubonic plague in humans. Flood conditions in Surat also could not be identified as a factor contributing to an epizootic of plague and subsequent epidemic of human bubonic plague.

DURING September–October 1994, Surat city in Gujarat State witnessed an outbreak of suspected plague (1027 cases) of which 52 died¹. Although Surat lies close to the northern tip of an erstwhile endemic centre along the eastern watersheds of the Western Ghats in Maharashtra State, the city does not figure in the endemic zone of western India². In May 1995, efforts were made to study the ecology of Surat city and human association with rodent habitats. The primary objective of these field observations was to identify factors which may have led to a plague epizootic among rodents with subsequent spill-over to humans leading to an outbreak of bubonic plague.

Extensive observations were made all over the Surat city with regard to housing pattern, population distribution, developmental activities and industries. Rodent burrows were examined at several places both in the town as well as the periphery of the city. Several interviews were conducted with the local population and the municipal health officials on rodent control activities in Surat city.

The urban area of Surat city is spread out in about 140 sq. km, with a population of about 1.5 million. The city is divided into 6 zones – North, South, East, West, Central and South-West (Figure 1). The North zone and part of Central zone are low lying areas. River Tapi passes through the city and separates the West zone

from the rest of Surat city. During the past 2 decades, the city has witnessed rapid expansion of the urban area on its periphery, and there has been gradual encroachment of ruderal sites as well as cultivated fields, for development of housing complexes. The general sanitary and hygienic conditions of these residential colonies were poor.

The Central zone of the city represents old Surat city and has the highest population density, with about 1/3 of the total city's population (0.5 million) residing here. The population in the 6 zones of Surat city (in descending order) is Central zone > South > East > North > West > South-west.

Surat is a highly industrialized city and the industries mainly comprise of diamond processing, metal works and polyester textiles. All industries are located within the city limits. The entire urban waste (solid, liquid as

well as industrial) is disposed off through wide open nallahs and, at some places, through closed city drains, into the river Tapti.

The periphery of Surat city has rapidly expanded, particularly in the North, West and South-west zones, with emergence of several slums. The South-west zone has mainly occupied ruderal habitats for urban expansion, but the North and West zones have encroached upon both waste land as well as cultivated land.

The urban area of Surat in the Central zone and its surroundings in the North, East, South zones (Figure 1) do not support habitat diversity congenial for survival of sylvatic rodents. However, the area is conducive for the growth of domestic rodents like *Rattus* species (e.g. *R. rattus*, *R. norvegicus*) and house mouse (*Mus* spp). The land, on both sides of the Tapti river appeared to harbour the field rodent *Bandicota bengalensis*. However, near the bank of Tapti, about 2.5 km away from Laxminagar colony (believed to be the *index case locality* during the September, 1994 outbreak), across a wide agricultural field of Ved village (North zone), a small circumscribed pocket of feral habitat with very a scanty population of wild rodent *Tatera indica* was detected, in dry sandy soil (Figure 1).

During the monsoon period (i.e. June–September) every year, the river water in Surat rises above the danger mark and enters the peripheral areas of the West zone. As a result, the few slum areas situated in this zone along the bank of the river, are adversely affected and the population temporarily shifts elsewhere. In the first week of September 1994, the floods in the river were of unusual magnitude (perhaps the highest in 25 years) and the flood waters entered the east of Tapti, inundating several localities in

North, South-west, Central and East zones of the city (Figure 1). Consequently the entire city waste from nallahs and drains, reverted back into the city due to pressure of water from the swelling river and remained *stagnant in the city for 5 days* (7–11 September 1994) and after the flood water receded, a large number of animals were found dead in the city. A comparison of monthly animal mortality (for 3 years) in Surat as recorded by the Surat Municipal Corporation is given in Table 1.

From an ecological standpoint, the circumscribed, small feral pocket away from human population is not supportive of initiating an epizootic of plague in *T. indica* which may spill-over, to cross the 2.5 km distance interspersed with cultivated land, and enter domestic biotope in Laxminagar colony. The absence of adequate ecological linkages between diverse habitats, essential for the dynamics of plague transmission, does not support the outbreak of bubonic plague in Surat city with its origin in feral habitats. Characteristic biotope associations are a pre-requisite to establish ecological linkages to support spill-over of wild rodent infection to humans^{3,4}. However, if the urban rodent population was enzootic for plague infection, there should have been bubonic plague cases reported even in the preceding years. The floods in September 1994 were of such high magnitude that they must have left many domestic rodents in the city dead along with their flea ectoparasites. The flood waters were highly polluted (containing human, animal and industrial waste), even large animals (cattle, buffalo, etc.) died in large numbers (Table 1). The number of dead animals in September 1994 was 4 and 5 times higher than in September of 1992 and 1993. These animal deaths can be attributed, both to drowning and chemical/organic pollution of flood waters.

Epilogue – What next?

V. Ramalingaswami

All India Institute of Medical Sciences, Ansari Nagar, New Delhi 110 029, India

The good news is, accepting the recommendation of TAC, the Government of India (vide their order no. T-21011/8/94-PH (Pt. 1) dated 24 April 1996) established a National Apical Advisory Committee (NAAC) for National Disease Surveillance and Response System. The Committee would have the responsibility of playing an advisory role in the establishment of a National Disease Surveillance and Response System.

The terms of reference of the Committee would be as follows:

1. The Committee would give advice and suggest mechanisms for setting up of a National Disease Surveillance and Response System.
2. The Committee would review the progress periodically regarding implementation of the National Disease Surveillance Programme.
3. The Committee would examine the epidemic preparedness of health care providers.
4. The Committee would assist and advise in the development of an early warning signal mechanism.
5. The Committee would review various programmes, guidelines and mechanisms available for prevention and control of communicable diseases with special reference to new, emerging and re-emerging pathogens and epidemic-prone diseases.

There is growing realization today that as new microbial threats are appearing, well-known illnesses thought to have been controlled are resurging¹⁻³. The Acquired Immuno-deficiency Syndrome (AIDS) is a good example of the former while malaria, kala-azar and plague are notable examples of the latter. Emerging or re-emerging, bacterial resistance to drugs is an increasingly serious problem. Population growth and consequent population movements from the hinterland into urban areas and into forest regions, changes in human behaviour, poverty and overcrowding, changes in ecology and climate, floods

and earthquakes, increased tourism, trading and traveling, the evolution and adaptation of microbes and the inadequacy and breakdown of health infrastructures are some of the factors behind the ever-changing scenario of infectious diseases^{2,4}. As far as plague is concerned, the importance of earthquakes, floods and local changes in ecology affecting microbe-carrying rodents and acting as triggering factors is well brought out in the preceding pages. While the canvas of NAAC's operations has been kept very wide covering all diseases, which is to be welcomed, it is to be hoped that Surveillance and Response Mechanisms for Plague and other Infectious Disease would receive the most urgent attention of NAAC for, after all, plague was the agent provocateur.

The essential task before NAAC is to advise the Government on national capability building related to preparedness, early detection and control of emerging and re-emerging infectious diseases and to establish proper disease reporting systems. Establishing the aetiological diagnosis, understanding the sources and modes of transmission of the infectious agents, identifying high risk groups, investigating antibiotic sensitivity of isolated microorganisms and facilitating the development and production of readily available reagents for diagnostic purposes are some of the elements of capacity building. Clinical samples and microbial isolates need to be referred expeditiously to designated laboratories in the country for further study and, at times, they may be referred to centres abroad and the WHO could be a useful ally in such tasks. While national networks of laboratories and scientists would need to be developed on a disease basis, it is equally important to participate in the establishment of a global disease surveillance and response network. The need for this is amply borne out by the fruitful interaction that took place between Indian scientists and scientists located in the WHO Reference Centres on Plague at CDC, Fort Collins (USA), Paris and Stavropol (Russia) in the plague outbreaks of 1994.

To meet the challenges posed by emerging and re-emerging diseases, a strong research and training effort in laboratory and field work is needed on a continuing basis. A cadre of well-trained microbiologists, epidemiologists, clinical scientists, behavioural scientists, entomologists, mammologists and public health professionals has to be built. The knowledge base generated by the research and training effort would enable the public health specialists to design appropriate control strategies and to provide the needed preventive and therapeutic tools. NAAC would need to work in close collaboration with the national research agencies (ICMR, CSIR, DBT, DST and others) and their laboratories in developing an integrated approach to national disease surveillance and response system and to ensure that the talent available in the country is fully utilized.

In the course of this work, TAC has realized the necessity of setting up appropriate containment facilities for handling hazardous microbes in the country. There is also an urgent need to establish laboratory facilities for collection, storage and maintenance of microbial strains isolated from various infectious disease outbreaks. The importance of this facility was brought home to TAC when it realized that despite many plague outbreaks in India, there are only a few old strains from these years that have survived in any of the national and world collections to compare with, thus severely limiting a consideration of the relationship of the strains isolated in the plague outbreaks of 1994 with pre-existing strains in the country and with strains elsewhere. In any national in-

fectious disease surveillance system, it is of the utmost importance to determine the origin of the infection and its relationship to earlier pre-existing strains of the infectious agents in a given area. The Department of Biotechnology is now coordinating an inter-agency initiative to address this issue.

NAAC's establishment represents a landmark in the story of India's struggle against tropical infectious diseases. Disease surveillance for disease prevention is a responsibility of the State and the resources needed must be found. Giving the Aryabhata lecture at the Indian National Science Academy on 4 October, 1994 (ref. 3), I said: 'Finally, attention was drawn to the need for increasing resources for sustainable health development and to the fact that securing the health of the people is a pre-requisite for maximizing wealth creation. Surat is a supreme illustration of the health rationale of development and of the futility of creating wealth without securing the health of those that toil for wealth creation'.

Book Review

Plagues: Their Origin, History and Future. Christopher Wills
HarperCollins Publishers, 77-85,
Fulham Palace Road, Hammersmith,
London W6 8JB, UK. 1996. 324 pp.
Price: £13.95.

The medical lexicon has usurped the word plague to refer to the disease caused by *Yersinia pestis*, although lay English usage (as in plagues and pestilence) adopts a much wider definition for the term. In his book, Christopher Wills also employs it in this larger context as he describes the toll of human mortality and morbidity exacted by a select list of infectious diseases both in the past and in the present-day world. Needless to say, India and its infamous plague epidemic of 1994 merit considerable attention in his discourse.

Implicit in the world plague is a sense of fear, morbid panic and mass hysteria, sometimes bordering on the unjust and irrational, and Wills does well to describe these reactions in respect of the diseases he chooses to cover: the plague, cholera, typhoid fever, malaria, tuberculosis, syphilis and, of course, AIDS. Strangely, the author excludes smallpox, a scourge comparable to those he covers, from his list. He does so on the ground that this disease no longer exists. But then an analogous argument could be made for syphilis, which has lost its sting, if not its bite, since the advent of the penicillin era.

I found Wills to be a fascinating story-teller. Without being encyclopaedic, he mixes history with science with anecdotal information and personal glimpses to sustain the reader's interest all through. For each disease in the list, Wills recounts (not necessarily in that order) its description in historical records, the discoveries associated with research on the infectious agent, its virulence characteristics and its mode of spread and the circumstances surrounding its epidemic outbreaks. The *Yersinia* plagues of the Justinian and the Black Death, the inconclusive debate on whether or not syphilis in Europe pre-existed Christopher Columbus, the controversy between Ronald Ross and Battista Grassi con-

cerning the discovery of malarial transmission by the *Anopheles* mosquito vector, the first documented experiment in epidemiology involving John Snow and the London Broadstreet water pump, and the saga of 'Typhoid Mary' are all recounted here, and in a manner refreshingly different from other accounts on these episodes that I have read earlier.

The author explains that each of these diseases represents but 'the eyes of the [submerged] hippopotamus' of infections in the affected communities and, moreover, that plagues are not confined to the human species but occur in other animals and plant species as well. He also discusses the interplay between pathogens and hosts in shaping the evolution by natural selection of each other's genetic make-up, and is particularly brilliant when he draws upon the analogy of tropical rainforest diversity in explaining the existence of extensive genetic polymorphisms in populations of both hosts and their pathogens.

A variety of events have to fall into place for an epidemic of vast proportions to occur, and breaking any one of the links in the chain is often sufficient to ensure that it does not propagate. 'It is one of nature's supreme ironies that, during the unusual juxtaposition of circumstances that leads to an outbreak of plague, all the major participants in the drama are sick. This includes the humans, the rats, the fleas, and the very bacteria themselves.' Wills attributes the low mortality associated with the Indian plague epidemic to the instantaneous and widespread use of insecticides and tetracycline. The author refers to these as 'Band-aids' that were successful in the short term but which do not address the underlying reasons that provoked the epidemic in the first instance.

I can fault the author on only one count in this book, which is that he repeatedly falls prey to the trap of anthropomorphic word play in describing the properties of the infectious agents. Witness, for example, 'The plague bacillus... is so fragile that it must be cautious. If it behaves with wild abandon and causes the plague, then most of the time it will die as well.' Or at another place, 'Like the strains of typhoid that

have managed to leave the tropics, the malaria species that have done so are more sophisticated than the one that was left behind. Temperate-zone malarias can conceal themselves... and they seem far more adept at surviving in their mosquito hosts.' To be sure, Wills himself is aware that these properties of the pathogens have not been actively acquired but passively selected in the course of biological evolution, and he uses these statements only to make the treatment of his subject less drab. But in these days of publicity for flesh-eating bacteria and machines that think, his presentation is bound to reinforce the pre-existing prejudice.

In the same vein, he addresses the question of the likelihood that a new disease will arise which is associated with both high mortality and rapid spread, and very reassuringly states: 'I am confident that no terrible disease will appear that slaughters us by the billion. The reason is that we can now respond very quickly to such a visible enemy.' I concur that the scenario of a new plague is extremely improbable, but for a different reason. The environmental niches occupied by humans today are not vastly different from those that existed at various times in the past (on an evolutionary time scale), and should a disease of the dreaded kind be waiting to occur, why has it not done so already? This is just another version of the anthropic principle, familiar to (but not necessarily agreed upon by) all physicists – that the very fact we exist today imposes constraints on the properties of the universe in which we live.

For whom is the book intended? Although it is charmingly written, I think it will still be heavy reading for the layman. But to any student (and I do not use the word in its strict pedagogic sense) of science, in particular of biological science – inclusive of medicine and agriculture – I believe that the book has plenty to offer. Wills educates even as he entertains. As is usual, however, the book is priced out of reach for the average Indian, but all libraries may be encouraged to obtain a copy.

I end this review on a personal note. Wills discusses, in a balanced manner, the controversy surrounding the nature

SPECIAL SECTION: THE PLAGUE EPIDEMIC OF 1994

of the etiologic agent responsible for the Indian epidemic in September–October 1994, and records the views of Jacob John from Vellore that it was not *Yersinia pestis*. On 1 October of that year, my wife and I travelled with our sons, then aged six and two, by train from Hyderabad to New Delhi; and then onward to Ludhiana on 4 October by another train that was on its way from Bombay to Amritsar, and that had indeed passed through Surat enroute. This was the time of the Dussehra school holidays, and yet both trains were running near empty. On a platform at the New Delhi railway station, one saw a set of tables that represented a make-shift plague surveillance unit, and many among the general population were moving around with surgical masks or

handkerchiefs tied across their faces. As Wills notes in his book, almost all international air carriers decided to overfly Delhi during those panic-filled days.

So were we being foolish to risk our lives and those of our children in undertaking this journey? Both of us had been students of Jacob John in Vellore and were certainly influenced by his statements, then widely reported in the press, that the Surat epidemic was not the plague. Now that the official report has proved him wrong, does ours become a foolhardy decision in retrospect? I still do not believe so. It was then already the third week since the start of the epidemic, and at least going by the press reports, the disease was not spreading as rapidly as the pneumonic plague is feared to do. Wills would attribute its

mildness to the large-scale consumption of tetracycline, but he was not there at the time. The antibiotic had simply disappeared from the market even in Hyderabad, where the scare was minimal; the increased consumption could not have occurred in the initial two weeks of the epidemic. My own hypothesis is that either the Indian epidemic was caused by a less virulent strain of *Yersinia pestis*, or the population enjoyed a certain degree of immunity to infection, perhaps because of cross-reacting antibodies. The Surat strains of *Y. pestis* demand further study.

INDIAN INSTITUTE OF SCIENCE BANGALORE 560 012

Applications are invited from Indian nationals preferably below the age of 35 years for a faculty position at the level of Assistant Professor in the Centre for Ecological Sciences. The candidates, if selected, are expected to develop and maintain independent research in any chosen area of ecology, behaviour and evolutionary biology as well as collaborate with other faculty and contribute to the teaching programme.

The candidate should have Ph D degree with about 3 years of postdoctoral research experience. Those who wish to develop new programmes of research in areas other than those in which they are presently working, or whose interests bridge basic and applied research are also encouraged to apply. Small start-up funds could be provided. The total emoluments at the minimum of the scale (Rs 3700–125–4950–150–5700) are around Rs. 1,23,000/- per annum. Interested persons should send (1) Curriculum vitae, list of publications, important reprints and names and addresses of three referees and (2) a brief description of the proposed research programme and the minimum facilities required for carrying it out, to **Prof. M. Vijayan, Chairman, Division of Biological Sciences, Indian Institute of Science, Bangalore 560 012, India**, within 45 days of the appearance of this advertisement. The referees may be requested to send their assessment directly to Prof. Vijayan.

For further details, please contact the Chairman, Centre for Ecological Sciences at e-mail address: ragh@ces.iisc.ernet.in or visit CES home page [Http://ces.iisc.ernet.in](http://ces.iisc.ernet.in).

Current Science, founded in 1932, is published by the Current Science Association in collaboration with the Indian Academy of Sciences. The journal is also intended as a medium for communication and discussion of important issues that concern science and scientific activity. All articles published in *Current Science*, especially editorials, opinions and commentaries, letters and book reviews, are deemed to reflect the individual views of the authors and not the official points of view, either of the Current Science Association or of the Indian Academy of Sciences.

INFORMATION FOR CONTRIBUTORS

GENERAL

All manuscripts should be addressed to the Editor, *Current Science*, P. B. No. 8001, C. V. Raman Avenue, Bangalore 560 080. Submission of an article will be held to imply that it has not been previously published and is not under consideration for publication elsewhere; and further, that if accepted, it will not be published elsewhere. *Three copies of contributions of all categories* are required, with a letter of transmittal giving (i) names and complete addresses of the authors and (ii) title of the contribution and the category in which it is submitted (see below).

Current Science is a multidisciplinary journal and therefore research and review papers of general significance that are written clearly and well organized will be given preference. All papers will be first assessed by a Reviewing Editor. Papers found unsuitable in terms of the overall requirements of the journal will be returned to the authors. The others will be sent for detailed review. *Both solicited and unsolicited material will be reviewed.* Authors of these papers will be notified of acceptance, rejection, or need for revision of the paper. Returned papers cannot be resubmitted. Illustrations and other material to be reproduced from other publications must be properly credited; it is the authors' responsibility to obtain permission for reproduction (copies of letters of permission should be sent).

CATEGORIES OF MANUSCRIPT

General articles (not exceeding 5000 words) discuss current trends in research in a field that will be of interest to readers outside the field; interdisciplinary topics: science policy and administration; or some aspect of the application of science and technology to human needs or the impact of science and technology on society/ecosystems/life. They should include a summary not exceeding 100 words, introductory paragraph(s), brief subheads at appropriate places to point to what follows, illustrations that will help a general reader, and references.

Review articles (not exceeding 5000 words) are expected to survey and discuss recent developments in a field. They should be well focused and organized, and avoid a general, 'textbook' style.

Research articles (not exceeding 4000 words) should report research results of fairly major significance. They should include an abstract not exceeding 100 words, introductory paragraph(s), and brief subheads.

Research communications (not exceeding 2000 words) should contain important findings that are novel and of fairly broad interest. They should include a brief abstract and an introductory paragraph. Text should not be broken up under subheads.

Correspondence includes letters, not exceeding 500 words, that are of general interest to scientists. All letters cannot be published.

Scientific correspondence contains technical comments, including those on articles or communications published in *Current Science* within the previous six months. Letters may be reviewed and edited.

Research news articles are intended to inform nonspecialists about recently published advances or important findings discussed at a meeting. Authors should also send a copy of the paper(s) on which the article is based. Meeting reports should avoid merely listing brief accounts of topics discussed, and must convey to readers the significance of an important advance.

Research accounts articles are intended to be personalized reviews of research from the authors' own laboratory, based on a body of published work. The articles must provide appropriate background to the area in a concise introduction, which should also serve to place the author's work in proper perspective. Articles will normally

not exceed 8 to 10 printed pages.

Opinion articles present views on issues related to science and scientific activity. **Commentary** articles should contain expository notes on issues related to science and scientific activity.

Book reviews. Unsolicited reviews will also be considered. Reviews that merely 'list' brief descriptions of the contents cannot be published. Reviews should have 'context' and convey some information about the subject of the book.

Historical commentary and notes inform readers about interesting aspects of personalities or institutions of science or about watershed events in the history/development of science; most are expected to relate to India. Illustrations are welcome. Brief items will also be considered.

MANUSCRIPT PREPARATION

Manuscripts should be typed double-spaced on one side of white bond paper (21×28 cm). The pages should be numbered consecutively, starting with the title page and through the text, reference list, tables and figure legends. The title should be brief, specific and amenable to indexing. Not more than five **keywords** should be indicated separately; these should be chosen carefully and must not be phrases of several words. **Summary** and **abstract** should not have more than 100 words and should convey the main point of the paper, outline the results and conclusions, and explain the significance of the results.

Text. All papers should have a brief introduction. The text should be intelligible to readers in different disciplines and technical terms should be defined. Tables and figures should be referred to in numerical order. All **symbols** and **abbreviations** must be defined, and used only when absolutely necessary. Superscripts and subscripts and ambiguous characters should be clearly indicated. **Units of measure** should be metric or, preferably, SI. Methods should, as far as possible, be described briefly in appropriate table and figure legends.

Figures. In the case of line drawings one set of originals (without any lettering) is sufficient, with two copies containing lettering. In the case of photographs good prints are required with each copy of the manuscript; photocopies are not acceptable. Line drawings should be roughly twice the final printed size. The correct orientation should be indicated if not clear.

Photomicrographs and other photographs that require it must have a scale bar, which should be defined clearly in the legend. Primary data should be submitted as far as possible (e.g. actual photographs of electrophoretic gels rather than idealized diagrams).

References should be numbered in the order in which they appear, first through the text and then through table and figure legends. The following are examples of ways of writing references.

1. Mukundan, T. and Kishore, K., *Curr. Sci.*, 1991, **60**, 355-362.
2. Constantine, G., in *Biology of Bats* (ed. Wimsatt, W. A), Academic Press, New York, 1970, vol 1, pp. 319-322.

Acknowledgements should be brief. Footnotes are not allowed except to identify the corresponding author if not the first.

Cover photographs. Good photographs (colour or black and white) that pertain to a submitted paper will be considered for use on the cover. Good *prints* and a legend should be submitted with the manuscript. In the case of a colour picture, a transparency will be required for printing if accepted.

PROOFS AND PUBLICATION

Two sets of galley proofs are sent to the corresponding author. A reprint order form accompanies the proofs.

TRNOESY

Nuclear Magnetic Resonance (NMR) has grown, during the last two decades, into an extremely powerful technique for studying structure, dynamics and interactions of biological macromolecules in aqueous solutions; thanks to the discovery of two-dimensional NMR in the early seventies, which allowed display of interactions between nuclei in a molecule onto a plane. Among the variety of 2D NMR techniques which have been developed over the years, nuclear Overhauser effect (nOe) based NOESY occupies a central place. It displays correlations between protons which are closeby in space and the intensities of the correlations are roughly proportional to the inverse sixth powers of the respective interproton distances. Quantitative interpretation of these pairwise correlations forms the basis of the accepted protocols for molecular structure determination today. Proteins and nucleic acid segments in the molecular weight range of 5–10 kDa are being investigated fairly routinely using these protocols. For larger systems the procedures are still evolving and are more demanding in terms of spectrometer and sample requirements.

In addition to the knowledge of the three-dimensional structures of the individual molecules, a similar knowledge about their complexes is crucial for understanding many of the biological functions. The difficulties and the complexities increase manifold, the moment one goes from isolated molecules to molecular complexes. Moreover, a protein molecule of functional interest may sometimes be too large for a detailed structure characterization with the presently established protocols. In such situations, 'transferred nOe' provides an elegant part solution. When the ligand for a protein macromolecule is small

and is exchanging rapidly between its free and bound forms, the nOe correlations observed reflect on the interactions in the bound form of the ligand, even though this may be a minor component in the solution. A NOESY spectrum displaying such 'transferred nOe' correlations is referred to as a TRNOESY spectrum. This technique has been successfully used by Maity and Jarori (page 906) to determine the conformation of ATP-Mg bound to a specific site on a large protein, namely, bovine serum albumin (BSA). They observe that, on protein binding, the sugar ring in the ATP molecule undergoes a substantial geometrical distortion. This is a reflection on the extent to which the three-dimensional structure of a protein can, in general, influence the conformation of a ligand bound to it by non-covalent forces.

R. V. Hosur

General relativity

This issue carries a Research Account by C. V. Vishveshwara entitled 'On the black hole trail...: A personal journey' (page 824). This was delivered at the IAGRG (Indian Association for General Relativity and Gravitation) annual meeting as the Vaidya-Raychaudhuri Endowment Award Lecture. As is well known in the community, Prof. C. V. Vishveshwara's Ph D thesis made a seminal contribution to the physics of black holes by settling the question of the stability of the Schwarzschild (i.e. nonrotating) black hole against small perturbations. This article provides some fascinating background to that work in terms of circumstances and personalities involved in General Relativity in the late sixties and early seventies. It then goes on to describe later work by the author and his colleagues in areas such as

quasinormal modes, gyroscopic precession, ultracompact objects, etc. and place it in the overall context of other developments.

R. Nityananda

Understanding the oceans

Biology, geology, oceanography and chemistry intersect in the special section (page 801–905) on the Joint Global Ocean Flux Study (JGOFS), which is a core project of the International Geosphere Biosphere Programme. The focus of the articles in this issue is the Arabian Sea which exhibits remarkable seasonal variations in biological productivity. Physical processes, most importantly monsoon-driven circulation, modulate biological events, which in turn affect CO₂ air-sea exchange fluxes and carbon cycling in the ocean. Understanding these events requires a marvellous interplay of physical, biological and geochemical studies, many of which are detailed in the special section. Painstaking observations in this area hold out the promise of future development of predictive models which may allow global scale predictions of the 'response of oceanic biogeochemical processes to anthropogenic perturbations, in particular those related to climate change'.

Lipid clusters

Studying cluster formations in diverse systems is a fashionable activity nowadays. Armed with ideas of fractal dimensions and scaling laws, Lahiri *et al.* (page 915) investigate the aggregation of phospholipid vesicles using straightforward microscopic methods. The demonstration

that addition of the cytoskeletal protein, spectrin, stabilizes cluster formation is of relevance in future studies of vesicular assembly.

Folklore and contraception

The Adivasi tribes in Bihar reportedly use the Banjauri plant (*Vicoa indica*) as a contraceptive, with a powdered

concoction being consumed by women. Following up on this practice, Rao *et al.* demonstrate the antifertility effect of dried Banjauri powder on female bonnet monkeys (page 918). The claims of folklore are investigated by modern scientific methods, providing a promising lead for future development of an active principle as an oral contraceptive. Three pure sesquiterpene lactones from this plant, vicolides A, B, C have been

characterized many years ago, with vicolide B having antifertility activity in rats. Whether new, as yet uncharacterized molecules are responsible for the observed effects and their mode of action should provide fruitful avenues for investigations in future.

P. Balaram

Current Science

SUBMISSION IN ELECTRONIC FORM

Authors who have been informed of acceptance of their manuscripts may send the final version in electronic form on floppy diskette (3.5" preferred; IBM PC format only, *not* Macintosh). The text of the manuscript only should be supplied as a plain ASCII file with no formatting other than line and paragraph breaks. (Wordstar 5.5 or 7.0 and Microsoft Word for Windows 6.0 are acceptable, but ASCII is preferred.) A hard copy of the text, with all typesetting information (italics, bold, mathematical type, superscripts, subscripts, etc.) must accompany the electronic copy. Tables and figures must be supplied only as hard copy. The diskette must be labelled clearly with the following: manuscript number, file name, file information (ASCII or Wordstar, version number, etc.).

Text may also be transmitted as ASCII only by e-mail to currsci@ias.ernet.in.

We expect that electronic submission will result in quicker processing for publication.

CORRESPONDENCE

Need to integrate science communication initiatives

Creating public understanding of science in an era when science and technology are permeating every fabric of society needs no emphasis. Despite some encouraging trends in recent years¹, various ongoing science communication initiatives and programmes at the national level need to be integrated under a single accountable authority to avoid duplication of efforts by multiple government agencies.

At the national level, for instance, the renaming and rededication of the New Delhi-based Publications & Information Directorate of the Council of Scientific & Industrial Research (CSIR) as the National Institute of Science Communication (NISCOM) on 25 September 1996 assumes a lot of significance². Interestingly, within the CSIR family, two more New Delhi-based institutes, viz. the Indian National Scientific Documentation Centre and National Institute of Science, Technology & Development Studies are also involved directly or indirectly in science communication.

On the other hand, the Union Ministry of Science & Technology has the popular science wing – the National Council for Science & Technology Communication

(NCSTC). In the recent past, two more outfits have emerged: the NCSTC-Network (a government-cum-voluntary-cum-nongovernmental body) and an autonomous organization, the *Vigyan Prasara*. Interestingly, one individual heads these three bodies. The NISSAT – National Information System for Science & Technology – also falls under the Science & Technology Ministry. Needless to say, the main objective of these set ups in one way or the other is science communication.

Specifically, for health education, the Union Ministry of Health & Family Welfare has a full-fledged institute – the Central Health Education Bureau which is located in New Delhi. And for environment awareness, the Union Ministry of Environment & Forests supports two centres of excellence. These are the Centre for Environment Education, Ahmedabad and the Madras-based CPR Environment Education Centre. The Delhi-based Defence Scientific Information & Documentation Centre of the Defence Research & Development Organization and the Ahmedabad-based Development and Educational Communication Unit of the Indian Space Research Organization are

also major players. Similarly the National Centre for Science Information (established in Indian Institute of Science, Bangalore in 1984) has been active in accessing and disseminating results of worldwide scientific and technological research to the faculty and researchers in universities and other research institutes in the country. Added to all this, the other major S&T agencies have their own Publication(s) and Information Division/Directorate. Even a large number of professional bodies such as the Society for Information Science, Indian Science Writers' Association, Health Media Centre – India and Energy Environment Group are painting a positive picture of science communication.

With this backdrop, there is an urgent need to integrate science communication initiatives.

Light and the future

Since global environmental and energy problems have reached an alarming situation, 21st century will be the 'age of

light' – particularly a period of exploitation of solar energy. Use of solar energy to combat pollution, to generate chemical energy (by water splitting) and to generate electricity (solar cells) has been reported extensively. Recently, in a two-day meeting, scientists from abroad and India assembled in Madurai to discuss current

trends in photophysics and photochemistry and solar energy conversion.*

As buckyballs are available for the scientists to play, J. P. Mittal (BARC, Mumbai) in his talk highlighted the very unique and interesting photochemistry and photobiology of fullerenes. Using modern laser techniques, the molecular processes

*A Satellite Symposium on Current Trends in Photophysics and Photochemistry was organized in Madurai Kamaraj University, Madurai, during August 5 and 6, 1996.

taking place in fullerenes within picoseconds following the absorption of light energy were studied. Surprisingly, fullerenes were found to be the most efficient compounds to produce singlet oxygen, a form of oxygen possessing high energy. Coupled with this ability and the selective absorption of fullerenes encapsulated in γ -cyclodextrin by cancer cells (compared to normal cells), the feasibility of application of fullerenes in photodynamic therapy, a technique where light energy is used to selectively kill cancer cells, was pointed out.

N. Alonso-Vante (Hahn Meitner Institute, Berlin, Germany) discussed the important role of the surface of semiconductors used in splitting water to H_2 and O_2 , a process where solar energy is harnessed to chemical energy. The results indicate that to tailor semiconductor materials for efficient solar energy conversion, the semiconductor surface is of vital importance besides the photophysics and photochemistry of the semiconductor. Using surface probing techniques such as scanning tunneling microscopy, the role of humidity and the surface structure stability in air were investigated for RuS_2 .

M. Chowdhury (IACS, Calcutta) spoke on the effect of magnetic field on the reaction of transient radicals (unstable intermediate products) produced. The magnetic field can also influence the transient species by bringing them together to form recombined product or to lead them to separate and form new products. The recombination of the photogenerated radical pair has been followed by luminescence from the recombined product (exciplex) and measurement of absorption of the transient radicals by laser flash photolysis. The magnetic field effect (MFE) on exciplex emission varies with the nature of the medium and this change is attributed to the change in the diffusive

motion. The role of polarity and ionic strength of the medium on the magnetic field effect was also highlighted.

Well-known inorganic complexes and organic dyes were incorporated into several synthetic polymers to produce light-absorbing macromolecules. Measurement of the lifetime of the light emission states of these macromolecules was used to map the environment around the light-absorbing antenna molecules. On the basis of these established facts, P. Natarajan (CSMCRI, Bhavnagar) discussed how to devise materials that can mimic photosynthetic biological systems for the production of value-added products from solar energy.

E. Pelizzetti (Univ. of Torino, Italy) focussed on how solar energy could be used to detoxify organic pollutants using the magic chemical titanium dioxide (Figure 1). When semiconductor particulates are irradiated by light, very reactive radical species are produced. Chlorinated organic compounds and some nitrogen compounds which get into the ecosystem by the use of pesticides, coolants, etc. are oxidized by the hydroxyl radicals and mineralized. He also explained how a model waste water treatment plant was in commission in Europe and how the operation of such a plant could be optimized by selecting proper supported photocatalytic semiconductors such as titanium dioxide, suitable light flux and efficient reactor design. For a country like India which has plenty of sunlight throughout the year, such a technique holds a great potential.

H. Tributsch (Hahn Meitner Institute, Berlin) discussed the new concept of proton transport (opposite to the movement of electron) in biomembrane followed by light absorption. Proton exchange with semiconductors such as $ZrSe_2$, TiO_2 , FeS_2 and $InSe$ and its

implications in solar energy conversion was explained. The photophysical processes in bacterial rhodopsin could be explained in terms of proton transfer model based on autocatalytic mechanism.

Photo-induced electron transfer is a key process in biological systems. The distance between molecules involved in the electron transfer is a critical factor for designing molecular electronic devices based on photochemical/photophysical properties. M. Kaneko (Ibaraki Univ., Japan) discussed the use of polymer membranes incorporating photoredox molecules to study electron transfer distances in model systems to understand whether the electron transfer is through chemical bonds or through space or via other mediator molecules.

One of the most promising techniques for solar energy utilization is the design of suitable photoelectrochemical cells. K. Kalyanasundaram (Swiss Federal Institute of Technology, Switzerland) discussed how solar cells can be designed to deliver conversion efficiency of nearly 10%. This efficiency is achieved by judicious choice of materials and appropriate molecular engineering of various components in the solar cell (Figure 2). For maximum light absorption polypyridyl complexes of transition metals were used as photosensitizers. The redox properties of these dyes were tuned to obtain sufficient driving force to convert absorbed light energy to the charge carriers in the semiconductor. Other factors such as solubility and long-term photostability of the sensitizers, good communication between the dyes and the semiconductor surface are also of critical importance to obtain a sustainable technology. Kalyanasundaram exhibited solar cells developed on these principles.

P. Ramamurthy (Univ. of Madras) discussed how radical intermediates formed by light absorption could be used for

Figure 1. Detoxification of organic pollutants using TiO_2 .

Figure 2. Materials and molecular engineering in photoelectrochemical cells.

production of polymers by taking triphenylpyrylium ion (TPP⁺) as the sensitizer. Using time-resolved light emission studies of the sensitizer, he explained the *in situ* generation of cationic initiators from iodobenzene (PhI). To understand the mechanistic details of the interaction between PhI and triplet state of TPP⁺, electron transfer quenching reaction was studied with a series of electron donors and the theories of electron transfer applied.

Because of their extensive use in tannery, the chromium complexes attract wide interest. T. Ramasami (CLRI, Chennai) explained the photochemistry of cobalt and chromium complexes. He explained how changes in electronic structures, geometries and solvents could influence the photochemistry of these complexes. The role of charge transfer excited states leading to different types of photoredox reactions was highlighted by taking some typical model systems.

S. Mazumdar (TIFR, Mumbai) illustrated the use of picosecond time-resolved fluorescence and anisotropy decay of natural porphyrins and their zinc complexes in anionic, cationic and neutral

micelles. The spectral data are consistent with the model, suggesting that the fluorescence depolarization occurs by both rotational and translational diffusion of the porphyrin inside the micelle along with the tumbling motion of the micelle as a whole.

From the surface photovoltage (SPV) studies, the reversal of the photocurrent in a liquid junction solar cell from n- to p-type characteristics was reported. This reversal is explained by preferential trapping of photoelectrons which supports the widely-held belief that charge transfer across a semiconductor-liquid interface occurs via trapped carriers. Based on SPV studies, the effect of humidity and film thickness on the ability of intrinsic semiconductors to generate photocurrent, the effect of etching on surface change and charge carrier sites have been investigated in the Weizmann Institute, Israel. G. Hodes gave a graphic account of the role of surface states in the photoelectrochemical properties of nanocrystalline CdSe films.

G. Prabhakara Rao (CECRI, Karaikudi) discussed the impact of chemically modified electrodes on many electrochemical

phenomena involved in photoelectrochemical cells. When potassium hexacyanoferrate was used as the chemical modifier, a large enhancement in photocurrent was noticed. However, dark current also increased owing to the formation of reactive intermediates, thereby restricting long-term stability of these electrodes.

P. Velusamy (Gifu Univ., Japan) elaborated the technology of obtaining thin lead oxide films and their interesting semiconducting properties. The photoelectrochemical and spectral responses and solar energy conversion efficiency of films grown using different electrolytes were analysed in the light of surface morphologies of the films.

The diversified topics covered in the meeting have been successful in channeling thoughts and experiments to harness and utilize solar energy and understand several photochemical and photobiological processes.

C. Srinivasan, Department of Materials Science, Madurai Kamaraj University, Madurai 625 021, India.

RESEARCH NEWS

Anomalous diamonds

Some recent reports of diamonds in rocks of crustal origin have added to the plethora of diamond finds outside the long established kimberlite (diatremes) source. These have shaken conventional notions that diamonds are solely mantle-derived, formed under high pressure and temperature (40 kilobars and 950°C), conditions not available in the crustal environment. Porous aggregates of micrometer-sized diamond crystals—carbonados—are examples¹ of non-kimberlite source showing attributes for a crustal origin. They are considered to be products of either transformed carbon subducted into the mantle or generated during impact metamorphism of carbon in rocks. Irradiation of organic carbon by fission fragments is found capable of inducing structural re-arrangement of carbon to diamond during the

radioactive decay of uranium in uraniumiferous sediments. Such nanometer-sized diamonds have been reported² from Precambrian carburanium—a fine-grained coal-like assemblage containing hydrous, carbonaceous material (with 5% uranium oxide)—occurring as brittle hygroscopic oval inclusions in pegmatite veins from North Karelia, Russia. These 40 nm sized diamonds were retrieved from the acid leached residues of the rock and their identity established by high resolution transmission electron microscopy. The find proves that 'carbonaceous material, catastrophically disrupted by energetic particles, can crystallize as diamond'², a process that will shortly be verified experimentally in a linear accelerator.

Diamonds of extra-terrestrial source^{3,4}, generated in the inter-stellar space, have

been found in iron meteorites and urelites and they are believed to have formed by vapour condensation. Clay beds from the impact crater site along the Cretaceous-Tertiary boundary (K-T boundary)⁵ were found to contain minute crystals of diamond. They are not considered extra-terrestrial but are supposed to be meteorite-impact induced as they show chemical and isotopic constituents typical of earthly materials. Another example of impact-related diamond has been reported⁶ from the 15 million-year-old Ries Crater in Germany. This is considered to have formed 'by chemical vapour deposition from the ejected plume of the impact crater' when carbon-bearing rocks vapourized during the impact.

Among the few other recent non-kimberlite diamond finds, is one from meta-

morphic rocks of southwest Norway carrying crystals, 20–80 μm in size⁷, generated when carbon-bearing sedimentary rocks were carried down to mantle depths temporarily during plate collision (with Scandinavia) and subsequently brought up to crustal levels. Some geologists doubt this, as they consider that crustal rocks are too buoyant to be carried down to mantle depths, and according to Stephen E. Haggerty, the well-known authority on diamonds, they were perhaps produced by a process akin to current industrial practice of making thin films of diamonds by chemical vapour deposition (CVD technique).

Even though the rather varied modes of occurrence of diamonds in nature have jolted conventional ideas about their genesis and exclusive association with kimberlites, the latter rock types still appear to be sole repositories for commercially viable crystals. Their ubiquitous existence and ability to survive over long geological time spans is of considerable significance as they can provide valuable information about impact structures and give 'access to events that occurred (and possibly carbon reservoirs that existed) in the early history of Earth when bombardment by meteorites was at its most intense'.

million years, and hence, oldest Ediacaran fossil). These organisms were globally distributed and belong to late Precambrian period, almost after 90% of geologic time had lapsed, during which life on Earth was represented by bacteria, algae and unicellular organisms. These soon gave way to larger and complex forms which were collectively called Ediacaran fossils and the period prior to Cambrian times were dominated by these forms so much that it came to be known as 'Ediacaran' marking the early Phanerozoic (greek for visible plus animal life)⁵ characterized by these oldest known multicellular life (metazoans). Martin Glaessner, 'the father of modern micropalaeontology', has provided detailed descriptions of these fossils, barring a few of which, most of them became scarce by about 500 million years. The fossils exhibited three dimensional preservation as sediment-filled moulds (i.e. body shape infilled with sediments without any trace of anatomical features) and without substantial flattening. Though palaeontologists initially classified them as animals, later researchers had expressed views that they may be plants or giant single-celled organisms or even as an unsuccessful evolutionary experiment completely different from known life on

Earth. In fact they were considered enigmatic for quite a long time.

However, recently a novel idea has come up that the Ediacaran fossils are remains of large lichens which had widespread development in the Precambrian and they were believed to be living symbiotically with algae and bacteria of those times^{8,9}. The animal-jellyfish connection suspected by the earlier discoverers was dismissed by experimentally proving that soft-bodied animals like jellyfish cannot leave any fossil impression as the weight of rocks piling over would have squeezed them much flatter and hence the Ediacaran fossils must have had structural strength and rigidity of the large plants having chitin. Like plants, they produced their own food and had microscopic tube-like structures similar to modern lichen filaments. These views have been discounted by other palaeontologists some of whom consider that the author had insufficient data and his conclusions based on structural strengths are flimsy as all Ediacaran fossils are merely impressions in rock and not fossilized remnants; also, their resemblance to sea-anemones (instead of jelly fish as earlier put forward) would be more apt as they had stiffer body. On anatomical grounds too, most of them

Ediacaran fossils – lichens?

In 1946, Precambrian fossil impressions of simple, soft-bodied organisms believed to be related to jelly-fish were described¹ from Ediacara Hills in Southern Australia and similar fossils were later found in Namibia, Ireland, China, Siberia, New Foundland, British Columbia, N. Mexico and in India^{2–7} (claimed to date 600

A few forms of the Ediacaran fossils.

bore resemblance to 'animals' though some forms like *Tribrachidium heraldicum* with three-fold symmetry, not seen in modern organisms, do not fit into any category. The biological enigma about these Ediacaran fossils still persists. Perhaps they belong to diverse groups – some resembling corals, some the mobile animals, while a few others, acellular; in fact they can be interpreted to represent a whole spectrum of organisms.

Paucity of preserved old crust

Though Earth's oldest crust formed more than 4 billion years ago, today researchers are baffled by the paucity of early continental crust. Different models have been put forward by them to explain this. According to one view, oceanic crust gets recycled into the mantle by plate tectonics while the continental crust, being too

buoyant to be drawn back into the mantle, had persisted and got weathered soon. Another view assumes that continental crust grew very gradually and their scarcity is due to their smaller size during Earth's early times and perhaps the creation of new crust and destruction of old ones had balanced since then.

An answer to the riddle about the rarity of early crust has come out of recent studies by Bowring and Housh¹ who through Sm–Nd isotopic studies have proved that indeed large segments of continental crusts have been recycled into the mantle during 4 billion years of Earth's evolution. They have used the progressive variation in the Sm–Nd ratios in the mantle reservoir through time as the basis for distinguishing older from later or 'juvenile' crust. The variation in the Sm–Nd ratio is brought about during the mantle differentiation which results in the formation of a buoyant crust. In this process, the newly formed crust gets preferentially enriched in Nd causing depletion of this element in the mantle reservoir through time. Thus the older of the early continental crusts will have ratios closer to the initial Sm–Nd ratios of the mantle and the younger ones, the products of mantle reservoir with depleted Nd, will correspondingly reflect the later Sm–Nd ratios. The analysis of fragments of early Archaen rocks indicate that even though large amounts of continental crusts formed early in Earth's history, they were subsequently destroyed and replaced by 'juvenile' rocks.

Direct unambiguous evidence of such recycling of early crust has come up recently in the find² of a diamond from a kimberlite pipe in N. E. Swaziland in Africa having as an inclusion, a crustal mineral – staurolite (an Fe–Al silicate).

This mineral is typically developed in metamorphosed clay-rich sediments and never reported from the mantle. This staurolite was apparently carried down into the mantle by subduction and later became encapsulated by diamond when the latter nucleated around it. The diamond was subsequently brought to the surface through the kimberlite magma. In another recent report³, a large chunk of peridotite in crustal gneiss in Alpe Arami region (Swiss Alps) has been found and this is considered yet another evidence of recycling of continental crust. Here, the large chunk of peridotite is believed to have been picked up by the continental gneiss of this region during its transit deep into the mantle (300 kms or more), when the gneisses were subducted during plate collisions, and subsequently brought back to the surface driven by buoyancy forces accompanying their warm up. In the process the gneisses underwent some metamorphism by the heat and pressure of the mantle. Fresh evidences are steadily coming up, establishing that recycling was an important process during the early history of the Earth and that the 'preserved continental crusts comprise of fragments that escaped recycling'.

Caution on the use of oxygen electrode-based assay for superoxide dismutase activity in crude preparations

Superoxide dismutases (EC 1.15.1.1) are a family of metalloenzymes that catalyse dismutation of superoxide radicals into oxygen and hydrogen peroxide. Growing literature in this area has signified the importance of superoxide dismutase (SOD) in imparting oxidative stress tolerance to plant and animal systems^{1,2}. This necessitated the development of a number of assay procedures to meet the experimental requirements³.

Flohé and Ötting³ and Beyer and Fridovich⁴ critically reviewed a number of procedures to assay SOD and highlighted some of the associated problems. Working with crude extracts of plant leaves poses a problem of green colour in the reaction medium, which interferes while assaying with any procedure based on spectrophotometry, e.g. NBT (nitro blue tetrazolium) reduction assay. Assay based on oxygen electrode⁵ eliminated some of the problems linked with other assays⁴ and the problem of colour in crude preparations was accounted for. In this assay procedure, riboflavin was photoreduced in the presence of EDTA (ethylene diamine tetra acetic acid, di-sodium salt); reoxidation of reduced flavin generated superoxide radicals utilizing oxygen molecules from the reaction medium. An oxygen electrode was used to monitor this depleted oxygen. In the presence of SOD superoxide radicals are disproportionated to oxygen, leading to the replenishment of the oxygen concentration of the medium. Therefore, an 'apparent inhibi-

tion' of oxygen uptake is recorded by the oxygraph. The degree of inhibition in oxygen uptake was used to calculate SOD activity.

However, the procedure suffers from a major drawback, particularly when applied to crude preparations. As mentioned earlier in a SOD catalysed reaction hydrogen peroxide is also generated. This hydrogen peroxide is likely to be decomposed into oxygen and water by the action of catalases (EC 1.11.1.6) present in the crude extract. Thus depleted oxygen from the reaction medium would be replenished by SOD as well as catalases activity. Consequently, oxygraph will record more inhibition in terms of oxygen uptake, leading to overestimation of SOD activity. Moreover, the procedure⁵ was reported without comparing it with any well-established procedure.

Our effort in the present communication is to study the interference caused by catalases in SOD estimation by oxygen electrode and NBT reduction procedures. Initially, oxygraph-based procedure was tested for its reliability by comparing with NBT reduction procedure, which is a very well accepted method for SOD assay.

Crude extract from leaves (1 g leaf homogenized in 10 ml of 50 mM potassium phosphate buffer, pH 7.8 containing 400 mg PVPP (polyvinylpolypyrrolidone); supernatant was used after centrifugation at 15,000 rpm for 20 min at 4°C) of tea (*Camellia sinensis*), pea (*Pisum sativum*) and barley (*Hordeum vulgare*) and purified

SOD from tea leaves was used to assay by NBT reduction and oxygraph procedures^{4,5}. SOD from crude extract of tea leaves was purified by salting out at 30–60% ammonium sulphate saturation. Precipitate was dissolved in phosphate buffer (pH 7.8, 10 mM), dialysed for 24 h against the same buffer and fractionated on a DEAE (diethylaminoethyl) cellulose column using 50, 200 and 500 mM KCl. The fraction with the highest specific activity for SOD (purified SOD), as determined by NBT reduction procedure, was used for our purpose. The purified enzyme was size-fractionated through a TSK column on HPLC (Data System 450, Kontron Instruments, Switzerland) using phosphate buffer (pH 7.8, 10 mM) at a flow rate of 3.0 ml/min and a major peak with highest SOD activity (extra purified enzyme) was used for experiments involving addition of external catalase (Sigma Chemicals; cat# C 2001).

Purified SOD was assayed along a temperature range of 15–35°C. Both the procedures showed maximum activity for SOD at 30°C with a very high correlation ($r=0.824$, data not shown). The two procedures responded similarly to different SOD concentrations ($r=0.982$, data not shown) along a large range of protein concentration. There was a shift in pH optima for SOD by the two procedures. NBT reduction method displayed maximum SOD activity at pH 7.8 whereas, oxygen electrode procedure revealed the best results at pH 7.4 (data not shown).

Table 1. Determination of SOD activity in crude extract and in purified enzyme by NBT reduction and oxygen electrode procedures^a

Enzyme preparation	SOD activity as per cent inhibition					
	NBT reduction procedure ^b			Oxygen electrode procedure ^c		
	A	B	C	A	B	C
Tea ^d	20.28 ± 4.80	19.48 ± 4.20	21.00 ± 3.65	48.35 ± 0.48	47.96 ± 0.40	61.56 ± 0.18
Pea ^d	22.24 ± 1.90	23.75 ± 1.60	22.86 ± 1.95	70.18 ± 0.87	71.62 ± 1.11	88.64 ± 1.21
Barley ^d	43.21 ± 4.90	44.54 ± 2.30	43.93 ± 5.00	73.00 ± 0.35	72.41 ± 0.53	90.35 ± 0.49
Purified enzyme	46.29 ± 0.66	45.95 ± 0.51	46.09 ± 0.19	29.50 ± 0.15	45.38 ± 1.60	70.77 ± 0.20

^a Reactions were carried out at 30°C; incident radiation, 1000 $\mu\text{E m}^{-2} \text{s}^{-1}$; separate blanks (with boiled enzyme) were prepared for each enzyme preparation.

^b Reaction medium: 0.05 M potassium phosphate buffer (pH 7.8) containing 5.7×10^{-5} M NBT, 9.9×10^{-3} M methionine, 1.17×10^{-6} M riboflavin and $2.5 \times 10^{-2}\%$ (w/v) Triton X-100 in a total volume of 3 ml.

^c Reaction medium: 5×10^{-5} M riboflavin, 1.5×10^{-4} EDTA and 0.5 μM KCl in a total volume of 3 ml of 0.05 M potassium phosphate buffer (pH 7.4).

^d Leaf material was used to prepare crude extract.

A = no catalases or hydrogen peroxide was included during assay; B = catalase (3 U; Sigma Chemicals; cat# C 2001) was included in the reaction medium; C = hydrogen peroxide (75 nmole) and catalase (3 U; Sigma Chemicals; cat# C 2001) added in the reaction medium. \pm represents S.E. values for three separate determinations.

The effect of sodium cyanide on inhibiting SOD activity was well recorded by the two procedures.

Although the correlation between the two procedures was very high, NBT reduction procedure always recorded more inhibition than oxygen electrode-based procedure when purified enzyme was used (Table 1). Such observed variations in enzyme activity by the two different procedures are not unusual. In fact, Beyer and Fridovich⁴ reviewed a large number of procedures for SOD assay and realized a vast difference in the amount of SOD required for 50% inhibition (0.004–0.73 µg SOD/ml) and pH optima (0.2–10.2) for various assay systems. Our results have shown that the amount of protein required for 50% inhibition by oxygen electrode procedure is about 1.5 times higher than that required for NBT reduction test.

While performing assay with catalases free, extra purified SOD enzyme, it was interesting to note that the addition of 3 U catalase (Sigma Chemicals; cat# C 2001) in the reaction medium showed a further inhibition in the rate of oxygen uptake by oxygraph procedure, but had no effect on NBT reduction (Table 1). Thus, the added catalase catalysed the decomposition of hydrogen peroxide into oxygen and water and the oxygraph recorded this change. Since NBT reacts directly with the superoxide radical and the oxygen molecules *per se* have no effect on it, hence no change was detectable by the NBT reduction method. Hydrogen peroxide in the reaction medium will be generated not only by the action of SOD, but the possibility also exists that self-dismutation of superoxide radicals would generate hydrogen peroxide⁶, leading to further release of oxygen by the action of catalases.

When SOD was assayed in crude extracts of tea, pea and barley by the two procedures, inhibition recorded was lower by 58.0, 68.31 and 40.8%, respectively in the NBT reduction method compared to oxygraph-based assay procedures. Our estimations showed very high catalases activity in the crude extracts. This probably explains a higher 'apparent inhibition' recorded by the oxygraph, as discussed earlier. Addition of external catalase in crude extracts had no effect on SOD estimations by the two procedures. Probably, catalases activity in the crude extracts was already present in optimum quantity.

In a separate experiment (Table 1), SOD activity by the two procedures was

assayed in crude extract as well as in extra purified enzyme in the presence of externally added hydrogen peroxide (75 nmole) and purified catalase (3 U; Sigma Chemicals; cat# C 2001). The NBT reduction procedure did not show any difference in SOD activity, whereas oxygraph procedure showed further inhibition that was attributed to the externally added hydrogen peroxide. Inhibition thus produced was very much pronounced in case of purified enzyme (139.8% more inhibition) compared to that observed with the crude extract (23–27% more inhibition). While it justifies our hypothesis further, the results with crude extract point out that apart from catalases other hydrogen peroxide scavenging systems, e.g. peroxidases, which would not release any oxygen molecule during catalysis, might also play a role. However, their contribution will depend on the availability of the substrate(s) in the crude extract. Catalatic or peroxidatic activity largely depends upon leaf age, environmental factors and so on. Hence, results obtained with the crude preparations using oxygraph may be misleading.

Some of the known inhibitors of catalases like salicylic acid⁷ or aminotriazoles⁸ inhibit catalases only partially, while cyanide inhibits catalases as well as copper and zinc containing superoxide dismutase⁹. It was not possible to inhibit either of the enzymes completely to show the role of catalases in overestimation of SOD activity. Therefore, additive rather than the subtractive approach was followed to solve the problem.

While the oxygen electrode-based assay procedure appears to be simple, it does not involve any expensive chemical like NBT and is ideal for coloured preparations, the presence of catalases and other interfering agents, e.g. peroxidases makes it impractical to work with crude preparations. However, the method could be used with highly purified SOD preparations.

D. Bhatnagar's response:

The determination of superoxide dismutase (SOD) by oxygen electrode (*Curr. Sci.*, 1995, **68**, 960–962) has not been presented for crude preparation and can be used, only with purified enzyme. The crude homogenates cannot be used in this method due to high amounts of peroxidase and catalase and other proteins which should be removed. However, when purified enzyme was used, addition of low concentration of cyanide (0.5 µM) to the reaction mixture inhibit catalase completely without affecting measurement of SOD activity. Low concentration of cyanide (5–50 µM) has been used to inhibit peroxidase and cytochrome oxidase in crude samples while high concentration of cyanide (1–2 mM) has been employed in the differential cyanide inhibition assay to inhibit CuZn SOD and permit the quantitation of both CuZn SOD and Mn SOD (Iqbal, J. and Whitney, P., *Free Rad. Biol. Med.*, 1991, **10**, 69–77). In crude preparations due to the presence of catalase, decomposition of hydrogen peroxide into oxygen will lead to erroneous determination of SOD.

Vision 2005: Earth Sciences

The Department of Science and Technology (DST) implements many programmes through which research is promoted in frontier areas of science and technology. The Science and Engineering Research Council (SERC) has played a pivotal role in this regard. Taking note of the global trends, SERC has decided to prepare 'Vision 2005 Document' in various disciplines. The Programme Advisory Committee on Earth Sciences has prepared a 'Vision 2005: Earth Sciences' document based on indepth discussions with a wide cross-section of the scientific community. The document indicates the areas of research in Earth Sciences that need to be given added thrust in future.*

Preamble

Man's inquisitiveness about and his dependence on environment and the processes contributing to its change form the basis of studies in Earth Sciences. Over the years, our understanding of the processes operating in the earth has increased considerably. This has led to a variety of new questions and new avenues of research. The emphasis today is to quantify the earth's endogenic and exogenic processes which control its internal dynamics and shape its surface and fluid envelopes, the sum total contributing to global change. Such a study involves not only the contemporary events and processes, but also those of the past, as what we observe today is a cumulative effect of the past and present processes. More recently, study of the interactions among the various components of the earth systems – lithosphere, hydrosphere, biosphere and atmosphere – has gained considerable importance as these interactions influence global change on various spatial and temporal scales.

Studies in the earth sciences in India are also slowly undergoing major changes. The current emphasis is to substantiate the classical approaches of exploration, description and data gathering with quantitative aspects of data processing, and interpretation of processes and events contributing to the observations. It is also evolving from a subject of individual inquiry to larger programmes involving scientists with complementary expertise and capabilities. Thus, earth science programmes are becoming more multi-institutional/multi-disciplinary, with increasing applications of the concepts and methods of mathematics, physics, chemistry and biology.

A major impetus for this shift comes not only from the need to understand and quantify better the spatial and temporal evolution of the Indian lithosphere but also from the recognition that such knowledge could form the basis for sustainable development of our natural resources. In addition, the recurrence of natural hazards has reinforced the need to learn more about the mechanics of these phenomena and develop predictive modelling capabilities.

The emerging challenges require, on a continual basis, appropriate human resource development in terms of skills and expertise, as well as facilities and infrastructure. The direct interface of the Earth Science Programmes with exploration/exploitation of both renewable and non-renewable natural resources (like energy, groundwater and minerals) calls for a much closer tie-up of its R&D programmes with the industry, user agencies and concerned government departments.

Resume of research activities in identified areas and their impact

India is a large country integrating a variety of geological features and phenomena. These include the Archaean cratons and their accreted mobile belts, the Himalaya – a classic example of continent – continent collision process, the Deccan volcanic province – one of the largest outpourings of continental flood basalts on the earth's surface, Proterozoic cratonic basins (Purana basins) of unique character, well-preserved sections of stratigraphic boundaries, some of the largest rivers of the world – the Ganga and Brahmaputra and a variety of well-preserved archives of past climates and environment. Extensive studies of these geological features have resulted in a number of important contributions in the field of earth sciences. Many of these studies stem from the thrust areas identified in the earlier DST document 'Challenging Areas in Earth and Atmospheric Sciences'.

*Composition of the Programme Advisory Committee on Earth Sciences: Prof. R. S. Sharma (Chairman), Shri D. N. Avasthi, Dr S. Krishnaswami, Prof. S. K. Tandon, Prof. S. K. Shah, Prof. C. Leelanandam, Prof. S. C. Sarkar, Dr M. Ramakrishnan, Prof. V. Subramanyan, Dr V. P. Dimri, Prof. S. Mitra, Prof. A. K. Jain, Dr K. R. Gupta (Convener) and inputs provided by Dr U. Raval, Dr S. K. Gupta, Prof. B. B. S. Singal and Dr R. K. Midha.

Future research directions: Objectives and research areas

Considering the available results of the completed and on-going researches, relevant panel reports and existing scientific and social environments, the task before us is to identify areas which hold promise for creative excellence and for the well-being of the society. It is expected that such areas would have a high likelihood of significantly enhancing our basic understanding of the geological processes/events and would yield results of general interest and application. This is indeed a difficult task even in the best of situations, because with the progress of research, new questions continuously arise which could drastically change the directions of enquiry. Nonetheless, we are listing below a few themes/areas for pursuing future research activities to enlarge our understanding of the earth processes. Other factors which have been considered in arriving at the list include: (i) the expertise of scientists, (ii) technology, manpower and financial support which are available at present and which may become available in due course, and (iii) the current international research trend. Additionally, future strategies in earth sciences must take into account basic and applied aspects in order to be able to cater to the ever-increasing human requirements.

While indicating the future directions, all areas/components of earth science were not considered; hence the topics listed below cover only selected disciplines.

Researches in other areas such as oceanography, limnology and atmospheric sciences, are being addressed to by specialized panelists of the DST.

Areas of opportunities

- i) Evolution of the Indian crust
 - 1. Precambrian cratons and mobile belts (including greenstone belts and granulite terrain)
 - 2. Purana Basins
 - 3. Phanerozoic Basins
 - 4. Mesozoic-Tertiary volcanic provinces
 - The Deccan and related traps
 - The Panjal traps
 - The Andaman arc
 - 5. Himalayan Orogenic belt
- ii) Structure and dynamics of lithosphere and mantle
 - 1. Continental crust (thermal structure, thickness and physical nature)
 - 2. Role of fluids (in geological processes)
 - 3. Experimental studies (phase equilibria and physical properties of deep interior)
 - 4. Lithosphere structure and plate dynamics
- iii) Earthquake processes
 - 1. Himalayan seismicity

- 2. Intraplate seismicity
- 3. Neotectonics and Palaeoseismicity
- iv) Reconstruction of palaeoenvironments, palaeoclimates and past global changes
 - 1. Infra-/inter-trappean sedimentary sequences of Deccan province
 - 2. Regolith sedimentology
 - 3. Palaeobiology and environmental shifts
 - 4. Quaternary sedimentation pattern, climate history and global changes
- v) Earth science application for societal needs
 - 1. Geohydrology
 - 2. Mineral resources and fuels
 - 3. Environmental geology and natural hazards
 - 4. Preservation of national heritage

The above-mentioned areas have been briefly discussed in the 'Vision Paper' with regard to some emerging problems under each theme. But we must realize that all geological problems start in the field, and it is strongly recommended that field study be recognized as an inherent and pervasive part of the research/education of earth sciences.

Interactive geoscientific studies

The geological sciences draw on tools and knowledge developed in other scientific disciplines. At the same time, geological research has contributed concepts and techniques to these other disciplines. For example, the structural determinations of high-temperature superconductivity drew heavily on mineralogical principles, and the similarity between the perovskite structure of these superconductors and mineral structure of large parts of the mantle is an example of closed relationship between geoscience and physical sciences. From the curiosity of studying geological materials on submicroscopic domains, the earth scientists also developed or refined several analytical devices (e.g. EPMA, Ion Probe, high P-T equipments) that were then applied in many other fields.

Increased understanding of the earth processes as well as emerging newer concepts and methodologies require interactive research programmes involving geoscientists, physicists, chemists, biologists and mathematicians. For molecular phylogenetics, a palaeontologist has to interact with biologist and organic chemists. Similarly, a petrologist and mineralogist would need a physicist to peep into the intricacy of heat and mass transport problems associated with matter in subcrustal depths. Even within earth sciences most research works are multidisciplinary about which an emphasis has been given in this document. Interactions seem to be legion, and most frontier research topics relate to more than one theme. Again, present day computational capabilities have revolutionized the

handling of vast amounts of data generated in earth science research. We now require to develop quantitative models for a number of earth processes. Even such traditional disciplines as mapping and palaeontology are becoming increasingly quantitative with the advent of digital analysis and computerized data base. The main emphasis of this theme is to recognize research problems in geosciences which need to be seen from different angles since solid earth of a geoscientist is in a way a science of solid state physics. To account for several earth science phenomena we also need to develop theoretical/mathematical models. Compilation of geological history and study of modern processes and their rates would allow mathematical modelling. For example, modelling is required for geochemical cycling, which brings together results from studies of various aspects, including mantle evolution, global tectonics, rock-water interactions, organic evolution and palaeoclimatology.

Numerical computer simulation is needed to develop, rather more rigorously, for a number of earth processes involving inputs from physical chemistry, statistics and other fields. We need accurate projection of the data-based interpretation for prediction of the natural processes. Even chaotic systems are subjected to statistical prediction. For example, the quantitative treatment of isotope exchange between rock minerals and fluids needs intensive integrated research in fluid-rock interaction and fluid flow within the crust. Many research problems of integrated nature can be conceived and formulated, but only a few are mentioned below.

In igneous petrology where study of silicate melts is made, geochemistry is definitely an essential research component. But to advance our understanding of many related processes, such as element partitioning between melt and crystals and crystallization sequence of minerals, a full knowledge of silicate melt structure is necessary. For this we need interaction with physicists and chemists. To study viscosity behaviour of melt, solubility of water in the silicate melts and structural nature of the melts, we need Raman Spectroscopy and polymer chemistry and related fields. In addition, spectra of ferrous/ferric iron requires knowledge of Mössbauer spectroscopy and crystal structure. Furthermore, to elucidate the petrogenesis of diversified igneous rocks, Rayleigh fractionation equation are used for elemental data so that vector calculations can be made for representing the composition of the derived liquids (resulting from the removal of given phases) and of cumulates (resulting from crystallization of model liquid). Clearly, we need inputs from experimental studies of crystal/liquid and element partitioning between them.

The lithospheric evolution of the Indian region forms an important interactive research area that would involve seismological, heat flow, magnetic, gravity, electrical, isotopic and geochemical studies of specified seg-

ments/transects in India. The studies may be carried out in stages as a multidisciplinary research project.

A long-term approach in metamorphic petrology is to outline P-T-t paths which indicate dynamic time-dependent character of metamorphism for a given crustal segment of overthrust belt. The geothermobarometry, based on thermodynamic principles, when applied to zoned minerals or to incompletely reacted mineral assemblages would help to define the paths of pressure/and temperature variation followed by the individual rocks. Chemical data on the zonation of minerals would additionally provide a wealth of information on the thermal processes that took place during metamorphism of rocks and growth of minerals. This shift of metamorphic petrology from a static mode (aimed at working-out the mechanical and thermal processes involved in metamorphism) needs numerical modelling. In this effort, the thermal response of the rocks to tectonism can be determined by computer modelling of the transient temperature distribution in a rock mass of specified physical properties, assuming certain boundary conditions. This forward approach complemented by petrological observations would unravel details of thermo-tectonic evolutionary history.

Manpower development and infra-structural facilities

The successful implementation of research programmes in any field requires personnel in various categories, appropriate infra-structural facilities such as equipments, current books and journals. India has a wealth of experienced earth scientists, but many of them are trained primarily in the classical approaches and are very specialized. The need today is more broad-based and earth scientists with good background in basic sciences, particularly mathematics and physics and chemistry, are required to carry out many of the interdisciplinary programmes and develop capabilities for modelling the results. In this context, there is a need not only to overhaul the current compartmentalized education system in earth sciences in the universities, but also to encourage scientists from basic sciences to immigrate to various areas of earth sciences. The earlier PAC had prepared a detailed document on Earth Sciences Education in India (*Current Science*, 1994, 67, 74-77).

To ensure front line scientific research in earth sciences, a continuous series of training programmes by way of workshops, summer schools, advanced short courses in selected topics, are required to be encouraged. Contact programmes need to be initiated particularly in institutions where infrastructural and instrumental facilities are available such as the WIHG, NGRI, PRL and IIT's. Interdisciplinary teams must be motivated to prepare instructional materials for dissemination. Refresher

- courses in modern trends in earth sciences with basics in physics, chemistry, mathematics and computer applications, mostly of remedial nature, should be formulated and distributed to various institutions/universities largely through video-lectures and correspondence materials.

Research in earth sciences, or for that matter any other disciplines, is considerably influenced by current awareness which in turn depends on the availability of a wide range of journals – both basic and applied. Indian universities in the recent past are faced with a major financial crisis, particularly in respect of library grants. The situation requires immediate redressal by way of long and short term measures. As a short-term strategy, there is an immediate need for five to six regional units equipped with computer database, such as GEOREF together with the required infrastructure for the dissemination of library materials to other users. Earth science data rely heavily on precise measurements. Collection of these data, particularly those dealing with geochronology, isotope systematics, chemical composition, requires sophisticated instruments. This is an area where most of the Indian universities and institutes lag behind the international scene. Consequently, we need to strengthen and augment the instrumentation facilities so that the country's research efforts can be maintained at an internationally competitive level. The approaches for strengthening and updating the instrumentation

facilities are discussed in detail in a separate document prepared by the PAC on this topic.

Conclusion

The potential and promise of research in earth sciences in India, both in basic and applied areas, are vast. The areas delineated in this Vision Paper should be interesting enough to stimulate a scientist in his imagination and to identify a specific problem, suiting his background, resources and infrastructural support that he may muster. The time is now opportune to follow-up some of the most challenging themes intensively by launching national programmes (interactive/multidisciplinary) through appropriate linkages between industry, universities, Government laboratories and survey organizations. Through these coordinated efforts and interaction between scientists of related and varied specialization we are expected to generate a more positive research environment whereby scientists would have access to library and instrumental facilities, with their maximum utilization. As a consequence, these would result in excellent research in the country whose spin off would naturally be toward the development of technology and science that would foster country's economic growth and meet societal needs as well as enhance defence, archaeology, dam, irrigation and geotechnical activities.

On the black hole trail . . . : A personal journey*

C. V. Vishveshwara

Indian Institute of Astrophysics, Bangalore 560 034, India

Beginning of the trail

It is a joy to give this talk as a tribute to Professors Vaidya and Raichaudhuri, the two father-figures of general relativity in India. If my talk is rather autobiographical in nature, the responsibility rests with Naresh Dadhich and Bala Iyer, respectively the President and the Secretary of the Indian Association for General Relativity and Gravitation, who persuaded me to make it so.

My personal journey along the black hole trail started in the sixties when I was a graduate student of Charles Misner at the University of Maryland. I had transferred from Columbia University in New York specifically to work with him. I had been encouraged to follow this course by Robert Fuller, my mentor at Columbia University and like Misner a former student of John Wheeler. Fuller had remarked, 'If you want to work in general relativity, why not go to one of the best in the field!' Also, that was when I first came to know about Vaidya and Raychaudhuri. Leepo Cheng was doing her master's thesis with Misner on the Vaidya metric. She was appalled by my ignorance when I told her that I did not know who Vaidya was. Later on, we were told that Raychaudhuri was coming as a Visiting Professor. Again, my colleagues were suitably impressed by my ignorance when I confessed that I did not know who this Raychaudhuri was either. I went on not only to take a course on cosmology from him but also to pass it with a little bit of honest cheating. Never did I dream that some day I would be delivering a lecture in honour of these two gentlemen.

Let me come back to black holes. That is not what they were called at that time. Schwarzschild singularity, which is a misnomer. Schwarzschild surface, which is better. The term 'Black Hole' was to be coined later on by John Wheeler. Perhaps, it was because of such an intriguing name that so many people were enticed into working on the physics of the black hole. This is known as the Schicklgruber Effect. Scholars have specu-

lated on how human history might have been different if Schicklgruber had not changed his name. But, he did change his name to Hitler. Misner proposed the following problem for my Ph D thesis. Take two of these entities that are now called black holes. Revolving around each other, they come closer as energy is radiated away in the form of gravitational waves. They coalesce into an ellipsoidal 'Schwarzschild surface' still rotating and radiating. Study the whole process, computing all the characteristics of the emitted gravitational radiation. Fine,

P. C. Vaidya

The Radiant Rider

Discoverer of the well-known Vaidya metric which represents the spacetime of a radiating star. Now in his youthful seventies, Vaidya rides his bike with such a star for the lamp.

*Text of 'Fourth Vaidya-Raychaudhuri Endowment Award Lecture' delivered on 17 February 1996 on the occasion of the XVII meeting of the Indian Association for General Relativity and Gravitation held at the Institute of Mathematical Sciences, Madras.

A. K. Raychaudhuri
The Cosmic Converger

Deriver of the extensively used Raychaudhuri equation which describes the motion of galaxies and shows how they must have emerged from an initial singularity in the past.

I said, thy will be done! No one at the time could have realized the magnitude of this problem. Had I pursued it, I might have entered the Guinness book of records as the oldest graduate student alive that too without financial support. Anyway, this proposed problem required the understanding of two aspects of black holes: the geometrical structure of a black hole and the perturbations of its spacetime.

Geometry of black holes

Those were the early days when very little was known about black holes. Wheeler was going around giving his talk 'Gravitational Collapse: To What?' with missionary zeal. There was some vague notion of the metric component g_{00} of static spacetimes tending to zero on some surface. I distinctly remember the cold morning when, on the way to grab a sandwich at the little store run by the school of dairy research, Misner suggested that I look into this shady business. Fine, I said, thy will be done! There were false starts. I had this excruciating experience of translating to myself a lengthy paper in German by Ehlers and Sachs – or was it Ehlers,

Kundt and Sachs, I forget – on ray optics and optical scalars in the hope that it would throw some light on the matter. It did not. Nevertheless, it was the article by Ehlers and Kundt¹ that gave the clue to the secret of the black hole structure. The covariant approach to the unravelling of the black hole geometry was via the spacetime symmetries or Killing vector fields. This way the fundamental properties of both Schwarzschild and Kerr black holes could be analysed, compared and contrasted. For instance, given a Killing vector field ξ one could derive the equation²,

$$n^a n_a = \frac{1}{2} [\xi^a \xi_a (\xi_{b;c} \xi^{b;c}) - \omega^r \omega_r], \quad (1)$$

where ω^a is the vorticity of the Killing congruence and n^a is the normal to surfaces of constant Killing norm, i.e.

$$\Sigma : \xi^a \xi_a = \text{constant}. \quad (2)$$

This shows that the surface on which ξ^a becomes null

C. W. Misner
The Master Mixer

Known for, among other things, his mix-master universe, cosmic isotropization by neutrinos, ADM formulation of general relativity, elucidation of the Taub-NUT spacetime, co-authorship of the black book *Gravitation*, and physics through spread sheets.

($\xi^a \xi_a = 0$), is itself a null surface, equivalently a one-way membrane or an event horizon ($n^a n_a = 0$), provided the vorticity also becomes null on the surface. The first condition implies that static observers cannot exist at and beyond this surface on which ξ^a is null. On the other hand, a null surface, satisfying the second condition, acts as a one-way membrane through which one can fall but cannot re-emerge from. This is the event horizon or the black hole. In the case of the Schwarzschild spacetime the surface on which the global timelike vector field ξ^a becomes null is a null surface since the vorticity of ξ^a is identically zero. In the case of Kerr spacetime, this is achieved for a suitable combination of the global timelike Killing vector ξ^a and the rotational Killing vector η^a . Consequently, the Schwarzschild black hole is both a one-way membrane and a static limit whereas in the Kerr spacetime, these two surfaces are distinct, thereby possessing the ergosphere between them. And this is where interesting phenomena like the Penrose process and the consequent energy extraction can occur.

Although the global timelike Killing vector field ξ^a of the Kerr spacetime possesses non-zero vorticity or rotation, Kerr spacetime admits an irrotational vector field

$$\chi^a = \xi^a - \frac{(\xi^b \eta_b)}{(\eta^c \eta_c)} \eta^a, \quad (3)$$

which is timelike down to the black hole. This vector field defines the Locally Non-Rotating Frames (LNRF)³, or the Zero Angular Momentum Observers (ZAMO)⁴. But this vector field exhibits much more interesting properties. These were investigated by Richard Greene, Englebert Schücking and myself⁵ around 1970. I had by then joined Schücking at New York University after a stint at the Institute for Space Studies of NASA in New York and a short period of unemployment. Perhaps it was too much to expect that black holes would be a source of income, since they were not sources of anything in the first place. To continue, we were able to generalize the irrotational vector field to arbitrary stationary, axisymmetric spacetimes with orthogonal transitivity. It was shown to be globally hypersurface orthogonal normal to $t = \text{constant}$ surfaces. These are maximal surfaces. The vector field could become null on an event horizon. Some features of this study, such as the physical interpretation of the mathematical conditions necessary for these properties, are still open problems. Incidentally, Iyer and I⁶ have recently renamed LNRF or ZAMO as GHOST – Globally Hypersurface Orthogonal Stationary Trajectories!

The geometry of Killing trajectories, i.e. the integral curves of Killing vector fields, that play such a basic role in elucidating the black hole structure, sneaked into our investigations in an indirect manner. Eli Honig was

studying the motion of charged particles in homogeneous electromagnetic fields using the Frenet–Serret (FS) formalism⁷. This formalism offers a geometric description of an arbitrary curve characterizing it by certain scalars and an orthonormal frame of reference at each point. In three dimensions these scalars are κ , the curvature and τ_1 , the torsion. In four-dimensional general relativity, we have an additional torsion τ_2 . Furthermore, the derivatives are with respect to proper time and, as a consequence, κ turns out to be the magnitude of four-acceleration. Similarly, the precession rate of a gyroscope carried along the curve has components τ_1 and τ_2 with respect to two members of the Frenet–Serret tetrad at each point of the curve. Now the worldliness of charges moving in a constant electromagnetic field F_{ab} bears striking resemblance to Killing trajectories. In both cases, each member of the FS tetrad satisfies the Lorentz equation. For Killing trajectories

$$F_{ab} = e^\psi (\xi_a \xi_b), \quad (4)$$

where the normalization factor $e^\psi = (\xi^a \xi_a)^{-1/2}$. In both cases, one can show κ , τ_1 and τ_2 are constants along the worldline and

$$\kappa^2 - \tau_1^2 - \tau_2^2 = \frac{1}{2} F_{ab} F^{ab}. \quad (5)$$

In the case of Killing trajectories, τ_1 and τ_2 turn out to be the components of vorticity. Further, acceleration is given by n_a , the gradient of equipotentials $\xi^a \xi_a = \text{constant}$, so that κ^2 is proportional to $n^a n_a$. With these substitutions, equation (5) reduces to equation (1). So, we have indirectly rederived the original black hole equation.

We shall return later to gyroscopic precession which we have mentioned here in passing.

Stability of the Schwarzschild black hole

The ultimate problem for my Ph D thesis, as mentioned earlier, was supposed to be the coalescence of two black holes. In order, at least, to make a beginning on this problem, I had to study perturbations superposed on the Schwarzschild spacetime as the background. The canonical paper in this area was, of course, the one by Regge and Wheeler⁸. To me this was a completely unknown territory. I remembered vaguely, a remark in Wheeler's book *Geometrodynamics*⁹ to the effect that the stability of the Schwarzschild spacetime was a problem far from having been solved satisfactorily. In fact, it was this book, totally incomprehensible to me when I was a first year graduate student in Columbia University and hence highly intriguing, that had drawn me towards general relativity. Another student of Misner, Lester Edelstein

and I rederived the perturbation equations and published them¹⁰ since these equations, as they appeared in the paper by Regge and Wheeler as well as at other places, contained errors. Lester was the first one to work out the radiation emitted by a particle falling into a black hole. He could not track down a factor of two that was missing when he compared his formula with the one of Landau and Lifshitz in the weak field limit. Unfortunately, as a result, he never completed his thesis and eventually switched from general relativity to actuaries. It was around this time that S. Chandrasekhar visited Maryland. It was a big event. Wheeler and his group, that included Uri Gerlach, Bob Geroch and Kip Thorne, drove down from Princeton. Chandra was getting interested in general relativity and in particular, black hole perturbations. We gave him our newly derived, yet unpublished equations. I had met Chandra a couple of years earlier at the Boulder Summer School in Colorado when I was aspiring to be a particle physicist in Columbia University. Other participating Indian students and I discussed with him our research as well as a bit of Indian science. In later years, I was to have the great privilege of having many discussions with Chandra on black hole physics, which became his chosen territory, and Indian science, in which he was keenly interested.

Stability analysis, as Ed Salpeter once put it, consists in finding out whether a system breaks apart if an ant sneezed in its vicinity. In the case of the black hole, the ant's sneeze is represented by metric perturbation which is a product of Fourier time mode $\exp(i\omega t)$, angular function which is a suitable tensor spherical harmonic and a radial function. Assuming the radial function to be well behaved, one had to show that imaginary frequencies that would make the perturbations grow exponentially in time were not admitted. Good behaviour had to be tested in reference to Kruskal coordinates that are singularity free at the black hole. Moreover, the radial functions corresponding to real frequencies had to be shown to form a complete set so that wave packets could be built that did not blow up in time. All this could be done for odd parity perturbations for which the radial function was governed by a Schrödinger-type equation with an equivalent potential. Frank Zerilli¹¹ would later derive a similar equation in the case of even parity perturbations. But, at the time, the even parity equation was a mess with frequency appearing all over the place. Stability analysis did not seem to go through. I was stuck, hopelessly stuck. Misner, who was going away to Cambridge for a year, suggested that I find a few simple, solvable problems and string them together into a thesis. My heart jumped into my mouth and my other organs rearranged themselves accordingly. I decided to devote another two weeks to the problem—body, mind and soul—and then quit if I did not make any progress. Those were the

days when Joe Weber was setting up his gravitational wave detector. Weber and his group were observing a rather peculiar phenomenon. Regularly around midnight the detector would record a sharp, beautiful peak. And then again another peak after an interval of a few minutes. Joe Sinsky, a graduate student, stayed on in the laboratory one night to investigate this puzzling phenomenon. Around midnight the door opened, a security guard came in and banged the door shut—the first peak. After making sure everything was secure in the laboratory he went out banging the door shut again—the second peak. Probably it was the same security guard who used to visit me around one in the morning. My working hours used to be from nine in the night to two in the morning. He would remove his shoes and his belt heavy with holstered gun, put up his feet on the desk and rest for a while. He would tell me what was going on in the world, including the parking lot, appreciate my working hard all alone through the night, sympathize with my non-existent wife waiting for me and then move on. On the eighth day from my decision to give stability a last try, my friend found me in a state of absolute euphoria. I had solved the problem. It had taken quite a bit of complicated analysis of the messy equation. Misner did not believe at first that the stability problem had been solved. But, after being convinced, he pronounced that my thesis was in the bag¹² and went away to Cambridge. And I, on my part, goofed off for one whole year.

Apart from establishing the stability of the Schwarzschild black holes¹³, the perturbation analysis had shown that the spacetime did not admit static perturbations that were regular at both the black hole and infinity. This was an indication that distorted static black holes could not exist in isolation. Nevertheless, it was startling to learn that Werner Israel had discovered the uniqueness of the Schwarzschild black hole¹⁴. There would be no potato-shaped black holes for instance. Nature had been robbed of her infinite variety. On the other hand, this clearly exhibited nature's simplicity. A static black hole could have only the shape of a sphere—the most perfect figure. After all, the philosopher Xenophanes, as early as in the sixth century BC, had declared that even God, being perfect, had to be spherical in shape!

Quasinormal modes

Halfway through the defense of my Ph D thesis, the examiner from the mathematics department asked the question, probably in a rhetorical vein, why one should bother to prove the stability of an object that was impossible to observe and was of doubtful existence in the first place. My thesis advisor did not like the question in the least especially coming from a mathe-

matician. The rest of the examination ended up as a verbal battle between the two which I watched with great satisfaction. But, the question remained: how do you observe a solitary black hole? To me the answer seemed obvious. It had to be through scattering of radiation, provided the black hole left its fingerprint on the scattered wave. I remembered from my first-year graduate course in quantum mechanics, how the reflection coefficient displayed maxima and minima in a wave scattered from a square barrier. In the case of the black hole also, the scattering was from a barrier, although of a different shape. So I thought, I might discover maxima in reflection coefficient characteristic of the black hole. In order to carry out this calculation you needed a computer, since the radial equation had to be numerically integrated. The days of the PCs were far in the future.

I was working at the Institute for Space Studies in New York where we did enjoy some luxuries. One of them was chilled beer that was sold at a quarter a can during seminars. So much so, the listeners soaked up more alcohol than astrophysics. The other luxury was computer time which was quite dear and scarce at other places. In addition, we had the help of a numerical analyst and a computer programmer. The reflection coefficient did show maxima albeit extremely faint. I became highly excited. But, when the range of integration was increased, the maxima shifted to some other frequency region. After quite a bit of computer experimentation, I decided that these were spurious maxima produced by the abrupt cut off of the effective potential. My conjecture was that a completely smooth potential would not give rise to maxima in the scattering cross section. I consulted Regge and Wheeler when I gave a talk at Princeton in 1969 with the alliterative title 'Schwarzschild Surface as a Stable Scattering Centre'. It was just before my seminar that I heard for the first time the term 'black hole' newly coined by Wheeler, which he illustrated with a picture of automobile junkyard he drew on the blackboard. Regge and Wheeler both agreed that there was no theorem connecting the smoothness of the potential to the non-existence of maxima in the scattering cross section. I still do not know the answer.

Although the scattering of monochromatic waves did not show obvious characteristics of the black hole, I felt that scattering of wave packets might reveal the imprint of the black hole. So, I started pelting the black hole with Gaussian wave packets. If the wave packet was spatially wide, the scattered one was affected very little. It was like a big wave washing over a small pebble. But when the Gaussian became sharper, maxima and minima started emerging, finally levelling off to a set pattern when the width of the Gaussian became comparable to or less than the size of the black hole. The final outcome was a very characteristic decaying

mode, to be christened later as the quasinormal mode. The whole experiment was extraordinarily exciting.

By the time the above work was published in *Nature*¹⁵, I had moved to New York University. Chandra made a visit and gave a talk on ellipsoidal figures of rotating fluids. He was very much interested in my work on scattering and in the phenomenon of decaying modes. Later on he was to compute the quasinormal mode frequencies with Detweiler¹⁶. Many calculations in this direction would follow finally culminating in the accurate determination of the frequencies by Nils Andersson¹⁷.

Quasinormal modes are generated in astrophysical scenarios such as gravitational collapse and coalescence of black holes. Ed Seidel has shown how well the fundamental mode matches the outgoing wave during the coalescence of binary black holes¹⁸. Recently Aguirregabiria and I have studied the sensitivity of the quasinormal modes to the scattering potential¹⁹. The motivation is to understand how any perturbing influence, such as another gravitating source, that might alter the effective potential would thereby affect the quasinormal modes. Interestingly, we find that the fundamental mode is, in general, insensitive to small changes in the potential, whereas the higher modes could alter drastically. The fundamental mode would therefore carry the imprint of the black hole, while higher modes might indicate the nature of the perturbing source.

Quasinormal modes are perhaps the rebuttal to the criticism of my thesis examiner regarding the nonobservability of black holes.

Ultracompact objects

One of the indirect offshoots of black hole research was the study of ultracompact objects or UCOs. While investigating the scattering of gravitational waves from the Schwarzschild black hole, I had noticed a peculiar phenomenon which I did not publish. Although at the time, the radial equation for even parity perturbations was quite complicated and was not in the Schrödinger form, it yielded exactly the same reflection coefficient as the odd parity perturbation for a given angular parameter l . One day I got a very excited telephone call from Chandra enquiring whether I knew this fact. I answered, yes, I did. Did I know why this happened? No, I did not. He had found the reason, he said triumphantly. He asked me for the numbers I had computed which I sent him. He went on to publish his interesting conditions under which two potentials lead to identical scattering cross sections mentioning my foreknowledge of the fact but not the reason.

It is the same story with neutrinos as well. The two equivalent potentials corresponding to the two helicities are quite different from each other²⁰, but lead to identical

reflection coefficients. One of them has the peculiar feature in that it has a potential well in the region $r < 3m$ attached to the usual potential barrier. This was terribly intriguing. Could there be a bound state in the potential well giving rise to some sort of neutrino trapping by the black hole? One can estimate the maximum number of bound states by integrating the potential over its spatial range. The well depth increases with the angular momentum quantum number and in the limit of its tending to infinity you get the answer one for the maximum number of possible bound states. In other words, there are no bound states.

I did not publish any of the above results. But out of it all another interesting question arose. Suppose you replaced the black hole by a spherical star of radius $r < 3m$. Then the potential well would not only exist, but would also be deepened by the enhanced gravitation of the matter. Could there then be bound states trapping neutrinos within the star? Ajit Kembhavi and I worked on this problem, found and computed the complex frequencies corresponding to the bound states of the neutrinos²¹. In a way, these neutrino bound states with complex frequencies were forerunners of the quasinormal modes of ultracompact stars worked out by Chandrasekhar and Ferrari²² as has been pointed out by Andersson²³. It is a very happy feeling that some of the problems I had worked on interested Chandra also.

Ultracompact objects with radius $r < 3m$ are in fact quite interesting entities. In principle, trapping of massless particles in their potential well is possible. Or the object can oscillate in its quasinormal modes. Van Paradis²⁴ has pointed out the peculiar behaviour of redshift for $r < 3m$. Recently, Abramowicz and Prasanna²⁵ have discussed the reversal of centrifugal force at $r = 3m$ for which you need a black hole or a UCO.

But, do such highly compact objects or stars with radius $r < 3m$ exist in nature? This question was considered by Dhurandhar, Iyer and myself^{26,27} and we also coined the name 'Ultra-Compact Objects' or 'UCOs'. By studying very carefully the general relativistic stellar models with different equations of state we established that, as a matter of fact, stable ultracompact objects can exist in nature.

Gyroscopic precession and inertial forces

We discussed earlier how the black hole structure can change dramatically when going from static to stationary spacetimes on account of the rotation inherent to the latter. The study of Killing trajectories in these spacetimes led to a covariant description of gyroscopic precession via the Frenet-Serret formalism. Precession is an important phenomenon. For instance, the Earth precesses. Ancient astronomers knew this. Astrologers did not,

thereby making predictions that were doubly wrong. Or, can two wrongs add up to one right? In atomic physics, Thomas precession, a manifestation of special theory of relativity, played a crucial role. Spacetime curvature gives rise to Fokker-De Sitter precession in the Schwarzschild spacetime. The spin of Kerr black hole contributes additional precessional effects. All these can be studied elegantly using the Frenet-Serret description⁶.

Another related area concerns the general relativistic analogues of inertial forces as developed by Abramowicz and coworkers²⁸. A particle at rest in a static spacetime experiences only the gravitational force, but is acted upon by the centrifugal force as well if it is moving uniformly in a circular orbit. In a stationary spacetime, there is an additional force, the Coriolis-Lense-Thirring force, which arises as a consequence of the metric components mixing space and time. In static spacetimes, such as the Schwarzschild spacetime, centrifugal force reverses at the circular photon orbit²⁵. So does gyroscopic precession. The situation is far more complicated in stationary spacetimes^{29,30}. My young colleague Rajesh Nayak and I have studied these effects and established covariant connections between gyroscopic precession on the one hand and inertial forces on the other³¹⁻³³. These considerations should be of interest in black hole physics from a conceptual point of view as well as for astrophysical applications.

The trail goes on . . .

I have tried to offer a glimpse, just a fleeting one at that, of my personal journey along the black hole trail. It has been a long journey spanning some three decades. There have been all sorts of ups and downs along the way. For instance, I have had my share of tussle with journals and referees. My very first paper¹⁰, the one with Edelstein, was unceremoniously rejected as nothing more than a bunch of formulae. Misner had to write a strong letter pointing out that the same journal that had previously published the wrong equations was now rejecting the correct ones. The paper on the structure of black holes² was also rejected as it was considered to be just mathematics and had to be published in the *Journal of Mathematical Physics*. The stability paper¹³ too had to cross some hurdles before seeing the light of the day. As with any important field, black hole physics has had its sociological factors sometimes leading to, among other things, inadequate recognition of significant contributions. All this becomes trivial in comparison to the exhilarating experience of exploration. It is a rare good fortune to have been trekking along the track right from the beginning. To have watched the seed germinate, the sapling sprout and the tree grow. It is also a good fortune to have had the company of

congenial co-travellers on the journey – marvellous friends to work with and keen minds to lead the way. If sometimes you stray away from the road, you keep coming back. Even now my colleagues and I are working on different aspects of black hole physics, such as quasinormal modes, rotational effects and black holes in cosmological backgrounds.

What is the most important lesson I have learnt having traversed the trail for so long? Let me answer that question by quoting the Spanish poet Antonio Machado, who wrote:

*Caminante, no hay camino
Se hace camino al andar.*

Traveller, there is no path,
Paths are made by walking.

It is gratifying, to feel that you have made a path however short, however narrow that has helped build a trail that was planned and paved by so many. It has been a joy to follow that trail. And I hope the trail will never end.

ACKNOWLEDGEMENTS. It is a pleasure to thank Sri Gujjar for his delightful drawings of Professors Charles Misner, P. C. Vaidya and A. K. Raychaudhuri. Many thanks are due to Ms G. K. Rajeshwari and Sri Rajesh Nayak for their help in the preparation of the manuscript.

JGOFS (India) – Introduction

The Joint Global Ocean Flux Study (JGOFS) is a core project of the International Geosphere–Biosphere Programme (IGBP), the main international scientific forum addressing issues pertaining to global change. The scientific goals of JGOFS were put together about a decade ago under the auspices of the Scientific Committee on Oceanic Research (SCOR). The main goals of JGOFS are:

- To determine and understand on a global scale the processes controlling the time-varying fluxes of carbon and associated biogenic elements in the ocean, and to evaluate the related exchanges with the atmosphere, the sea floor, and continental boundaries.
- To develop a capability to predict on a global scale the response of oceanic biogeochemical processes to anthropogenic perturbations, in particular those related to climatic change.

To accomplish these goals a detailed implementation plan with specific scientific objectives have been formulated. One of the key components of this plan is *process studies* in selected *biogeochemical provinces* in the oceans which can significantly influence the global carbon budget. Among the biogeochemical provinces identified by the international JGOFS community, one of them is the Arabian Sea known for its high and seasonally oscillating biological productivity resulting from monsoon-driven circulation. In addition, the northern regions experience enhanced biological productivity in winter which has been attributed to convective overturning associated with winter cooling. One of the goals of the JGOFS programme is to assess the variations in primary and new production and the flux of carbon through the water column during different seasons, especially that arising from the monsoonal circulation. The effect of these physical and biological processes (upwelling, biological productivity) on the CO₂ air–sea exchange fluxes, carbon cycling in the water column and its burial in the sediments is not well understood and is a topic of considerable interest and debate among oceanographers. The international JGOFS community during the past 3–4 years have been conducting major campaigns in this oceanic region, particularly in the monsoon-induced upwelling areas of the western and central Arabian Sea to address the above issues.

The JGOFS (India) programme was seeded during the international symposium on the 'Oceanography of the

Indian Ocean' held at the National Institute of Oceanography, Goa, January 1991. The Department of Ocean Development constituted a Steering Committee to generate, monitor and implement JGOFS programme in India. An interdisciplinary, multi-institutional project was formulated for JGOFS-related studies in India with focus on central and eastern Arabian Sea. Broadly the goals of the JGOFS (India) programme are (i) to assess the role of the Arabian Sea in the overall CO₂ air–sea exchange balance by determining the magnitude and direction of CO₂ air–sea exchange fluxes during different seasons; (ii) to determine the primary and new production rates, their spatial and temporal variations, the export flux of carbon from the euphotic zone and its relation to primary productivity, (iii) study of the records of deposition of carbon and other elements in the sediments of the Arabian Sea, particularly in its margin and their relation to water column processes; (iv) to investigate the role of margin sediments in influencing the chemistry of the Arabian Sea interior. Scientists from the National Institute of Oceanography (Goa), Physical Research Laboratory (Ahmedabad), National Chemical Laboratory (Pune) and Centre for Mathematical Modelling and Computer Simulation (Bangalore) are participating in JGOFS (India) programme.

The JGOFS (India) programme is currently in its mid-way. During the last two years it has completed three major sampling expeditions to the eastern and central Arabian Sea. The first cruise (SK-91) was undertaken during the pre-monsoon season, April–May, 1994. This was followed by a winter cruise (SK-99, February–March, 1995) and a monsoon cruise (SK-104, July–August, 1995). All these expeditions by and large followed the same track, however, sampling in the northern latitudes could not be done during the monsoon cruise because of logistical problems. In addition, a fourth expedition is currently underway (August, 1996) and a fifth one is planned for January, 1997.

This special section of *Current Science* contains the first collection of articles of the JGOFS (India) programme, most of the papers deal with the results from the intermonsoon (SK-91) and winter cruises (SK-99). The articles by S. Prasanna Kumar and T. G. Prasad (page 834) and by P. M. Muraleedharan and S. Prasanna Kumar (page 842) provide a comprehensive overview of the physical oceanography of the central and eastern Arabian Sea, including the near-coastal regions. Their results suggest that during winter, the northern Arabian

Sea surface waters experience densification due to excess evaporation over precipitation and turbulent heat loss in excess of radiative heat gain. This causes sinking and convection which pumps nutrients into surface waters from deeper layers, enhancing biological productivity. These studies demonstrate for the first time through direct observations the effect of winter cooling on the mixed layer dynamics of the northern Arabian Sea and associated enhancement in biological productivity.

The spatial and temporal variations in primary productivity and chlorophyll distribution are addressed in the article by P. M. A. Bhattathiri *et al.* (page 857). They observe that during winter the primary production and Chl *a* abundances in the northern latitudes were about a factor of two higher than those during the preceding intermonsoon season, consistent with that expected from changes in circulation. The highest productivity measured in this region ($\sim 800 \text{ mgC m}^{-2} \text{ d}^{-1}$) is about a factor of 2–3 lower than that reported for the north western Arabian Sea during the SW monsoon, but is similar to that observed in the north Atlantic during the JGOFS North Atlantic Bloom Experiment.

Fundamental to all biological processes is the nature and availability of solar radiation in the ocean. This important aspect has been studied by T. Suresh *et al.* who measured (February–March, 1995) the photosynthetically available radiation in the eastern and central Arabian Sea. The peak values observed were in the range of 365 to 435 W m^{-2} . In addition, aerosol optical depth measurements yielded values from 0.07 to 0.19. These measurements have great relevance to remote sensing, validation of algorithms and models, and the peculiarity of the Arabian Sea where oscillation of high rates of primary productivity under more or less constant levels of solar radiation take place.

The articles by S. Sawant and M. Madhupratap (page 869), M. Madhupratap *et al.* (page 863), N. Ramaiah *et al.* (page 878) and M. Gauns *et al.* (page 874) discuss various issues pertaining to the abundance and distribution of phytoplankton and zooplankton, bacteria and micro-zooplankton respectively. The abundance of bacteria decreased drastically from intermonsoon to the winter season. The high abundance during the low productive intermonsoon period is probably sustained by the dissolved organic pool that may build up as the bloom tapers off. The standing stock of bacterial carbon during intermonsoon was significantly higher than that of phytoplankton, thus contributing to much of the POC in the region. The mezo-zooplankton abundance studies attest to the Arabian Sea paradox of its general invariance with productivity. This paradox, most likely results from the switch over of the feeding pattern of the mezo-zooplankton, from phytoplankton during productive sea-

sons to microbial loop during oligotrophic periods. This is also attested by the observation that microzooplankton carbon was higher than meso-zooplankton standing stock.

The influence of water circulation and biological productivity on the nutrient and oxygen distribution in the water column are presented by S. N. De Sousa *et al.* (page 847). During winter, intense reducing conditions occur in the intermediate waters resulting from sluggish water movement coupled with higher biological productivity. The studies revealed the occurrence of nitrate reduction in all seasons in sub-oxic waters, which is maximum (10 μm) in winter.

The measurements of the air–sea exchange fluxes of the greenhouse gases, CO_2 , CH_4 and N_2O are presented in the articles by V. V. S. S. Sarma *et al.* (page 852) and Shyam Lal *et al.* (page 894). The pCO_2 values in surface waters were generally higher or equal to those in the atmosphere, with values of about 420 μatm during winter and between 360 and 420 μatm during intermonsoon and monsoon seasons. These results suggest that the central and eastern Arabian Sea serve as a source of CO_2 to the atmosphere, typical flux being \sim a few $\text{mmoles m}^{-2} \text{ d}^{-1}$. Analogous to CO_2 , this region of the Arabian Sea also supplies CH_4 and N_2O to the atmosphere, with higher fluxes during winter. The next step in these studies should be to have a better understanding of the various water column processes contributing to the production and consumption of these gases which would enable development of models to quantify their air–sea fluxes.

The application of ^{234}Th : ^{238}U disequilibria in the surface waters to derive information on particle and carbon export fluxes and time scales solute–particle interactions are discussed by M. M. Sarin *et al.* (page 888). They observe that the residence time of chemically reactive elements like Th in surface waters of the Arabian Sea is about a month. More importantly, these authors observe that the export flux of carbon at 100 m, estimated from ($^{234}\text{Th}/\text{C}$) ratios measured in sediment trap materials and ^{234}Th deficiency in the water column is significantly higher than primary productivity. These results raise concern about the source of carbon to the traps and the underlying assumptions in using ^{234}Th as a survey tool for estimating carbon export.

Another important area of study of the JGOFS (India) programme is the sedimentary record, which provide data on the temporal variations in the burial fluxes of several biogenically important elements, and their relation to water circulation and productivity history. A large number of sediment cores from the continental margin of the Arabian Sea have been collected and are being analysed for a number of diagnostic tracers to decipher the environmental history of sediment deposition and

their role in regulating the distribution/removal of trace elements in the water column. The article by D. N. Yadav (page 900) addresses to one of the issues, viz. cycling of carbon in the sediments mediated through manganese.

Data management and modelling are two other areas of study which were initiated as a part of JGOFS (India) programme last year. The data and results of JGOFS (India) programme are stored and managed at the Indian National Oceanographic Data Centre (INODC) at NIO, Goa. Scientists from the Centre for Mathematical Modelling and Computer Simulation, Bangalore are in the process of developing a coupled basin scale model of the Arabian Sea circulation and biogeochemical cycles.

The results of these process studies hopefully will be incorporated into predictive models. However, long term continuous time series observations using moored data buoys with sensors which measure selected parameters would have to be deployed in the Arabian Sea to fully understand the biogeochemical processes. Ideally this should be supplemented by remote sensing techniques. Future work would thus have to be in this direction. In addition, work similar to the JGOFS could be initiated in the Bay of Bengal, which has its own unique and special oceanographic characteristics and which necessarily has to be investigated if one aspires to predict processes on a global scale.

The JGOFS (India) is funded by the Department of Ocean Development (DOD), New Delhi. We gratefully

acknowledge the support, interest and encouragement received from DOD for the programme. Special thanks are due to Prof. V. K. Gaur, the then Secretary of DOD and the current Chairman of the JGOFS (India) Steering Committee whose personal interest has helped considerably in implementing this programme. Dr P. R. Rama Rao, former Secretary, DOD, Dr A. E. Muthunayagam, Secretary, DOD, Mr B. N. Krishnamurthy, Director, DOD, the members of JGOFS (India) Steering Committee, the Technical Evaluation Committee of *ORV Sagar Kanya*, Dr B. N. Desai, former Director of NIO, and Dr E. Desa, Director, NIO all have contributed to the programme and we acknowledge their support and encouragement. The articles in this special section were reviewed by national and international experts in the field, their reviews have helped considerably in improving the manuscripts. On behalf of JGOFS (India) programme, we thank all these reviewers.

Winter cooling in the northern Arabian Sea

S. Prasanna Kumar and T. G. Prasad

Physical Oceanography Division, National Institute of Oceanography, Dona Paula, Goa 403 004, India

The upper thermo-haline structure and the surface meteorological parameters of the central and eastern Arabian Sea during the inter-monsoon (April–May, 1994) and winter monsoon (February–March, 1995) periods, were analysed to understand physical forcing that leads to the observed high productivity during winter in the northern Arabian Sea. The weak northerly winds and increased solar insolation during the inter-monsoon period, led to the development of a highly stratified upper layer with warm sea surface temperature (SST) (29.5°C) and shallow mixed layer depth (MLD) (25 m). In contrast, during winter, the upper thermo-haline field showed a dramatic change, with cold SST (25°C) and deep MLD (100 m) in the north, though the winds were weak (5 ms⁻¹). The atmospheric forcing that leads to the observed changes in the upper layer of the ocean is a combination of enhanced evaporation under the influence of the dry continental air from the north brought by the prevailing northeasterly trades and reduction in the solar insolation. Subsequent cooling and convective mixing injects nutrients into the surface layers from the thermocline region, which in turn triggers the primary production.

It is well known that during summer monsoon (June–September) upwelling is a dominant mechanism which triggers plankton bloom and results in extremely high productivity in the Arabian Sea^{1,2}. In contrast, the spatial variation in the productivity during winter (November–February) is less studied. On the basis of analysis of published data, Banse³ inferred that the central Arabian Sea is more productive than subtropical gyre elsewhere, and the area north of 20°N to be richer than the central Arabian Sea. Our results from a recent Indian Joint Global Ocean Flux Studies (JGOFS) cruise, during February–March 1995, revealed the evidence of high productivity in the northern Arabian Sea, the details of which are presented elsewhere, in this issue⁴. In this article, we analyse the upper thermo-haline structure and the physical forcing that lead to the observed high productivity.

Data and methods

As a part of the Indian JGOFS programme, 36 CTD (Conductivity Temperature Depth) profiles were collected at one degree interval (up to 1000 m depth) onboard ORV *Sagar Kanya* during 4 February to 4 March 1995 (Figure 1a). In accordance with the

JGOFS protocol⁵, Sea-Bird Electronics CTD was used to obtain temperature and salinity profiles. CTD salinities were calibrated against water samples collected simultaneously by a rosette sampler and analysed with a Guildline 8400 Autosol. The conversion of conductivity to salinity was made using the modified UNESCO formula⁶. The data collected during the JGOFS cruise of 14 April to 14 May, 1994 (Figure 1b) were also utilized to highlight the changes in the water column. Apart from the CTD profiles, surface meteorological parameters were also collected during both the cruises. The surface meteorological observations on a 2° × 2° grid from the Comprehensive Ocean Atmosphere Data Set⁷ (COADS) were used to obtain monthly mean values of surface heat flux and evaporation. The surface fluxes (Wm⁻²) were calculated using standard bulk aerodynamic formulae⁸ for latent (Q_e) and sensible (Q_h) heat exchange:

$$Q_e = \rho L C_e (q_s - q_a) U,$$

$$Q_h = \rho C_p C_s (T_s - T_a) U,$$

where L is the latent heat of vaporization, C_p the specific heat of water, q the specific humidity, C_e and C_s the empirical exchange coefficients, T_s the sea surface temperature, T_a the air temperature, U the wind speed. The evaporation is computed by using the equation

$$E = \rho C_e (q_s - q_a) U.$$

The precipitation data were obtained from the Very High Resolution Radiometer (VHRR) onboard the INSAT (see ref. 9 for details). From these data, monthly mean precipitation on a 2° × 2° grid was generated. Further, monthly values of evaporation–precipitation (E–P) were computed along 64°E.

Results

To understand the physical process, we analysed the observed surface wind as well as the vertical structure of temperature, salinity and sigma- t along the 4 legs (Figure 1).

Winds

The surface winds during February–March (Figure 2a) were predominantly north/north-easterlies with occasional north-westerlies. Along the shelf, the observed

Figure 1 *a, b*. Location map of CTD stations occupied during (*a*) 4 February to 4 March (winter monsoon) 1995 and (*b*) 14 April to 14 May (inter-monsoon) 1994. H indicates profiles taken with hydrocast.

Figure 2 *a, b*. Wind vector during (*a*) winter monsoon, (*b*) inter-monsoon.

wind speed varied between 4 and 7 ms^{-1} , except at 18°N where it was about 12 ms^{-1} . In the open ocean, the wind speed showed a gradual increase from about 2 ms^{-1} to 5 ms^{-1} towards south. During April–May (Figure 2 *b*) the surface winds south of 17°N were predominantly

northerly and weak (<4 ms^{-1}), but became progressively stronger towards north. Along the northern shelf, the wind speeds were between 8 and 10 ms^{-1} , decreasing to 6 ms^{-1} towards south. In the open ocean, wind speeds were high north of 18°N reaching up to 8 ms^{-1} .

Thermo-haline characteristics

Winter monsoon (February–March)

The thermal structure during February–March, along the shelf (leg 1), (Figure 3, top panel) showed a weakly stratified surface layer extending to 100 m depth, and the sea surface temperature (SST) rose from about 24.2°C in the north (21.5°N) to about 29°C at 10°N, approximately 0.5°C increase per degree latitude. The mixed layer depth (MLD), in general, was deep varying between 120 m at 21°N and about 80 m at 10°N. The packed isotherms below 100 m, along the southern shelf, indicated a strong thermocline. Salinity structure (Figure 3, bottom panel) also showed a weakly stratified layer of high salinity (36.4 PSU), in the north, thinning towards south. The very low salinity waters (< 34.6 PSU) towards south indicate the influence of the Bay of Bengal waters, being carried along the shelf by northward flowing coastal current. The high salinity surface waters (36.4 PSU) in the north is the Arabian Sea High Salinity Water mass (ASHSW), the core of which deepens towards south (about 100 m depth) and was identified by the 36.0 PSU isohaline.

Along 64°E (leg 3), the thermal structure showed a weakly stratified surface layer extending to 100 m

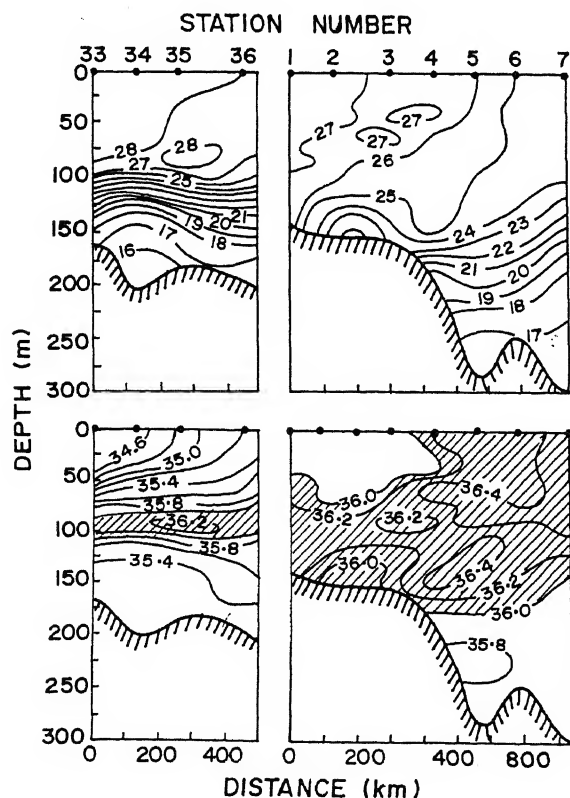

Figure 3. Vertical section of temperature (top) and salinity (bottom) along the shelf during winter monsoon. Salinity >36 PSU is hatched to demarcate the Arabian Sea High Salinity Water mass.

depth, as seen along the shelf, with colder waters (<25°C) north of 17°N, while south of it, the SST increased to 27°C (Figure 4, left panel). Thermal structure depicts deep mixed layer in the north (21.5°N) which shoals to about 80 m at 20°N and once again deepens to 125 m at 17°N. South of 17°N, mixed layer depth shoals steadily, reaching up to 65 m at 11°N. Isotherms below the upper thermocline showed considerable shoaling towards south giving rise to strong gradient in the lower thermocline as well. This thermal structure essentially reflects the zonal flow pattern in the open ocean circulation. Below 500 m, the waters are well stratified with no appreciable north–south variation. Salinity structure (Figure 4, middle panel) showed the presence of ASHSW near the surface (> 36.4 PSU) in the northern region, the core of which deepens towards south. The surface salinity decreased from 36.4 PSU in the north to less than 35.7 PSU at 11°N. This low salinity water is the indication of North Equatorial Current (NEC), which carries along with it the low salinity waters from the Bay of Bengal as well as the eastern Indian Ocean into the western Arabian Sea during this season. The second subsurface high salinity (36.0 to 36.2 PSU) seen between 200 and 400 m in the north and spreading southward is the Persian Gulf water mass, which was also seen spreading eastward along leg 2: As it moves southwards beyond 14°N, the water mass loses its identity due to mixing with the Red Sea water mass, normally encountered south of 13°N, between 400 and 800 m depth and sigma- t 27.0, which is manifested by the thick isohaline layer between 200 and 800 m depth near 11°N. The sigma- t structure (Figure 4, right panel) mainly reflects the combined effects of thermo-haline structure. In the northern region, sigma- t greater than 24.5 was encountered at the surface with thick isopycnal layer (100 m), which gradually decreases southward and becomes as low as 22.0

The MLD along the zonal section (nominally along 10°N, leg 4), increased gradually from about 50 m in the west to almost 100 m towards the east with SST in general, warmer than 28°C (Figure 5, left panel). The packed isotherms in the upper 300 m indicate the signature of the NEC active during the winter monsoon. The presence of NEC brings about drastic changes in the surface salinity along this section (Figure 5, right panel) with very low salinity waters (34.6 PSU) from the eastern side over-riding the high salinity waters of the west. The core of the ASHSW (36.0 PSU) consequently showed an eastward deepening. The thick isohaline layer between 200 and 1000 m (which thins towards east), once again is the admixture of Persian Gulf and Red Sea waters.

Inter-monsoon (April–May)

Along the western shelf (leg 1), thermal structure

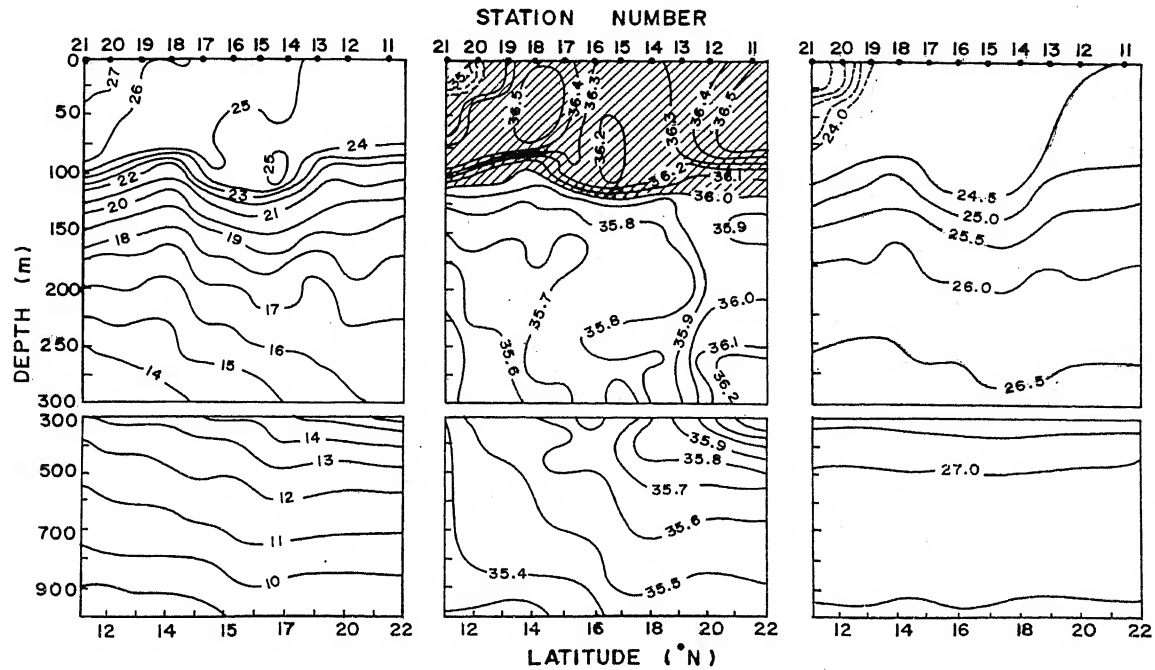

Figure 4. Vertical section of temperature (*left*) salinity (*middle*) and sigma-*t* (*right*) along 64°E during winter monsoon. Salinity >36 PSU is hatched to demarcate the Arabian Sea High Salinity Water mass.

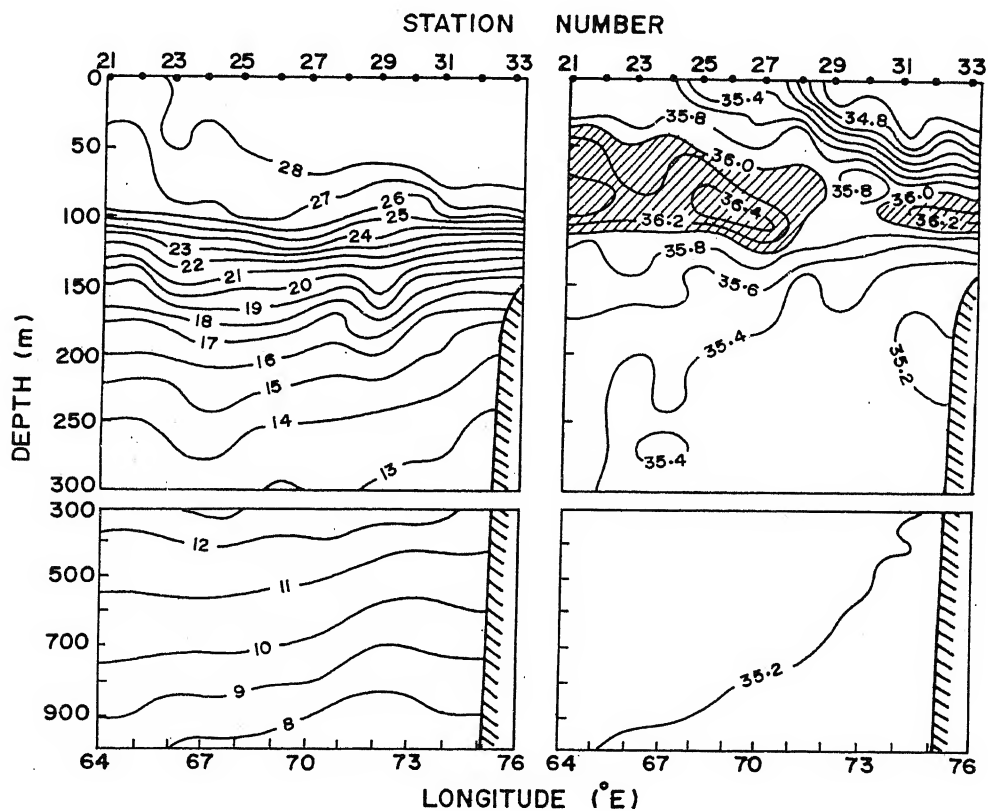

Figure 5. Vertical section of temperature (*left*) and salinity (*right*) nominally along 10°N during winter monsoon. Salinity >36 PSU is hatched to demarcate the Arabian Sea High Salinity Water mass.

showed thin mixed layer, varying marginally from 10 m in the north to 25 m in the south, with SST more than 30°C (Figure 6, top panel). More or less uniformly thick, high salinity waters (36.4 PSU) are encountered along the northern shelf, north of 16°N (Figure 6, bottom panel). However, along the southern shelf, low salinity waters are seen in the upper 20 m. The core of the ASHSW, which is seen almost at the surface in the north, deepens to about 80 m towards south.

The thermal structure along 64°E (leg 3) showed a well-stratified surface layer. The upper thermocline showed an overall trend of deepening from 21°N to 11°N, except between 13.5°N and 15.5°N where isotherms greater than 20°C shoals, appear to be a signature of a meso-scale (cold core) eddy (Figure 7, left panel). The MLD remained thin showing a general deepening, though small, toward south as in the case along the western shelf (leg 1). Salinity structure resembled that during February–March, except for the reduced spatial extent of the low salinity water in the southern region (Figure 7, middle panel). The thick isohaline layer seen in the north, during February–March, is no longer present. Instead, the high salinity (36.6 PSU) protrudes into the water column, indicating the spreading and deepening of the ASHSW towards south. Unlike during February–March, the sigma- t structure showed the presence of low density waters uniformly throughout from 21°N to 11°N (Figure 7, right panel) and strong stratification. The 24.5 isopycnal seen at the surface in the north during winter monsoon is not encountered at 60 m.

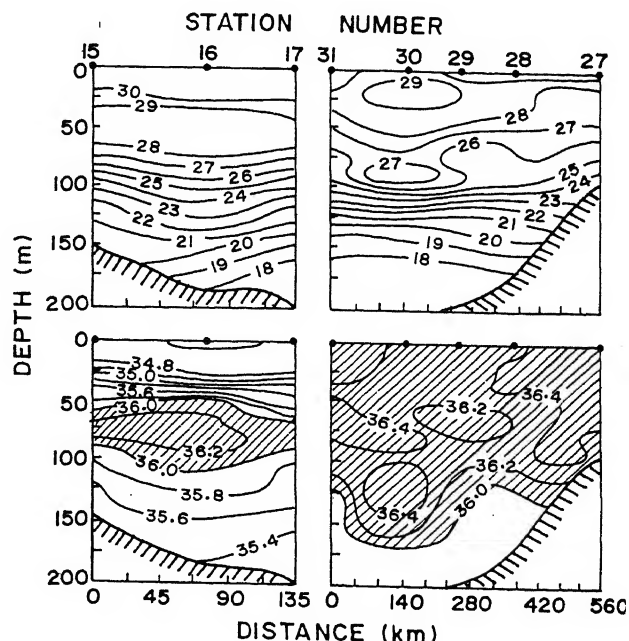

Figure 6. Vertical section of temperature (top) and salinity (bottom) along the shelf during inter-monsoon. Salinity >36 PSU is hatched to demarcate the Arabian Sea High Salinity Water mass.

Along leg 4 (nominally along 10°N), thermal structure showed extremely shallow MLD in comparison with February–March with the mixed layer temperature

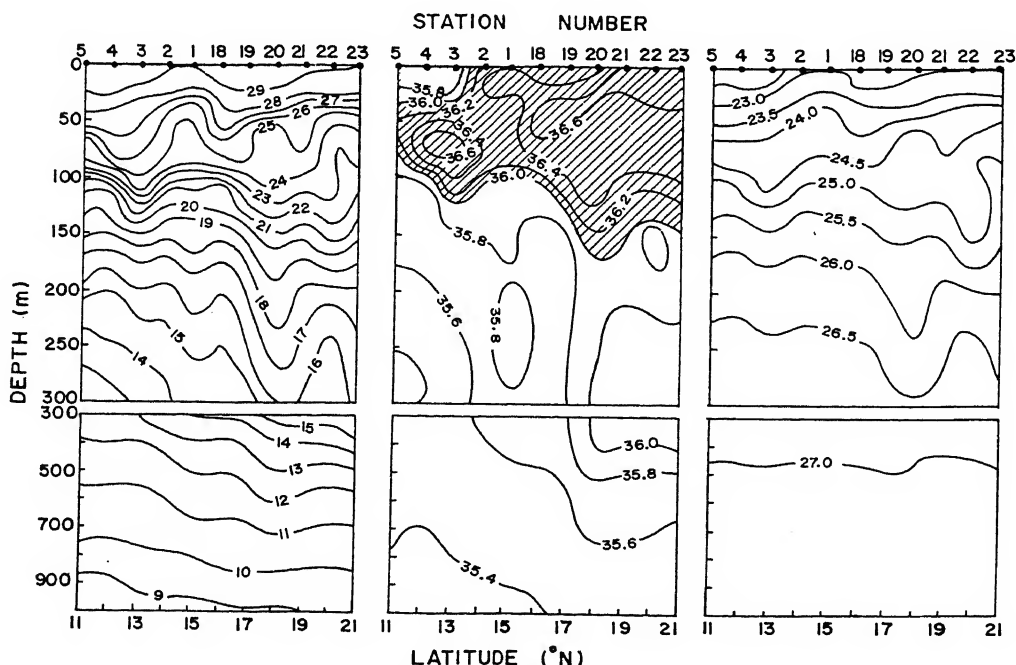

Figure 7. Vertical section of temperature (left) salinity (middle) and sigma- t (right) along 64°E during inter-monsoon. Salinity >36 PSU is hatched to demarcate the Arabian Sea High Salinity Water mass.

Figure 8. Vertical section of temperature (left) and salinity (right) nominally along 10°E during inter-monsoon. Salinity >36 PSU is hatched to demarcate the Arabian Sea High Salinity Water mass.

at least 2°C warmer (Figure 8, left panel). Though, in general the salinity structure was similar to that during February–March, the haline gradient seen at the eastern region is diffused (Figure 8, right panel). The thickness of the ASHSW also showed considerable change.

Surface meteorological parameters

To highlight the changes of the top layer of the ocean during winter monsoon, we over-plotted the air temperature, SST and MLD of inter-monsoon period along 64°E (leg 3).

The air temperature, during winter monsoon, increased from 23°C in north to a little more than 26°C in the south, while it was, in general, more than 28°C during inter-monsoon, and at times reached up to 30°C (Figure 9 a). The SST showed about 3°C rise from north (25°C) to south, in winter as compared to 1°C rise in inter-monsoon (Figure 9 b). The MLD during winter was deep (100 m) in the north (Figure 9 c), which shoals up to 80 m at 20°N and once again deepens to 120 m at 17°N. South of this MLD shoals steadily reaching up to 65 m. In comparison to winter monsoon, MLD was very shallow, varying between 10 m in the north and 35 m towards south, during inter-monsoon.

To understand the atmospheric forcing that lead to the observed changes in the upper thermo-haline fields, we analysed the heat and fresh water (evaporation–precipitation) fluxes along 64°E.

The time-latitude distribution of the latent heat flux along 64°E showed two high values, one during November–January, specially north of 10°N (130 Wm⁻²), and the other during May–August (220 Wm⁻²) in the central Arabian Sea (Figure 10 a). The sensible heat flux showed heat gain in the central Arabian Sea from June

Figure 9 a-c. Distribution of (a) air temperature, (b) SST and (c) MLD. The solid line indicates winter monsoon and broken line inter-monsoon.

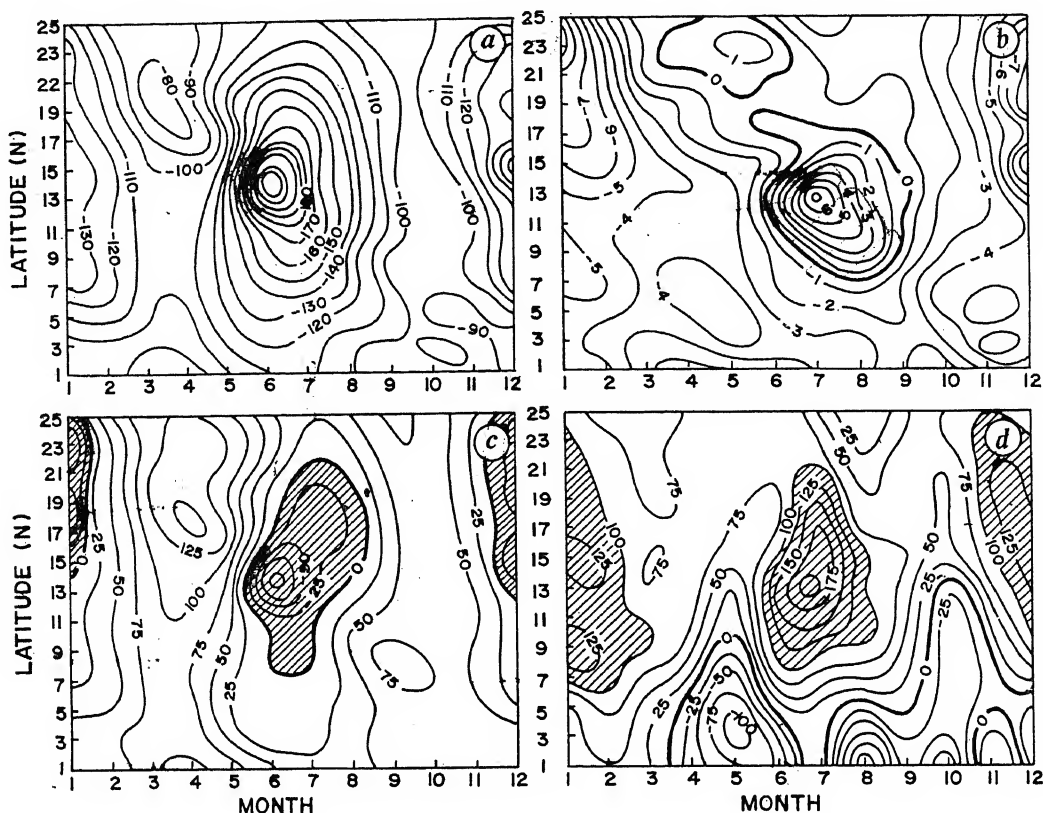

Figure 10 *a-d*. Time-latitude section of (*a*) Latent heat flux (Q_e , Wm^{-2}), (*b*) Sensible heat flux (Q_s , Wm^{-2}), (*c*) Net heat flux (Wm^{-2}), and (*d*) evaporation-precipitation ($E-P$, mm/month) along 64°E . The hatched region in (*c*) represents a net heat loss while that at (*d*) shows where evaporation exceeds precipitation by more than 100 mm/month .

to September, while the northern Arabian Sea experienced significant heat loss during winter monsoon (about 7 Wm^{-2} , Figure 10 *b*). The net heat flux (Figure 10 *c*) pattern was similar to that of latent heat flux. $E-P$ depicted a net fresh water loss north of 12°N , with two distinct maxima, one in summer (200 mm/month) and the other in winter (125 mm/month) monsoons (Figure 10 *d*). Throughout the year, the equatorial region receives excess precipitation over evaporation.

Discussion

The above analysis of the upper thermo-haline structure and the surface meteorological parameters brings out the interesting changes from winter monsoon to inter-monsoon as well as the predominant north-south variations. The thermal structure during April-May showed a thin mixed layer, varying from 20 to 35 m, with SST more than 29°C . The core of the ASHSW, seen below the surface in the north, deepens while spreading towards south. Unlike this, during February-March, the thermo-haline structure showed considerable changes in the upper layers. The most dramatic change takes place

in the mixed layer, which becomes deeper than 90 m in the north, reaching up to 120 m at 17°N , while towards south it is shallower (about 65 m). A weakly stratified upper layer was observed, both along the shelf as well as in the open ocean. The surface meteorological conditions during April-May showed predominantly weak northerly winds south of 17°N , which becomes progressively westerlies and stronger towards the north. This indicated the prevalence of north-east monsoon conditions south of 17°N , and setting in of south-west monsoon north of it (Figure 2 *b*). The increase in SST ($>29.7^\circ\text{C}$) over the air temperature (on an average 28°C) indicated the increasing solar insolation during this period (Figure 9 *a*), making the upper layer of the ocean highly stratified. Under the prevailing weak wind conditions and increasing solar insolation, one expects a rather thin and more or less uniform MLD as observed (Figure 9 *c*). During February-March, the winds were weak throughout, on an average 5 ms^{-1} , and were predominantly north/north-easterly indicating the prevailing winter monsoon conditions (Figure 2 *a*). North of 17°N , the air temperature (Figure 9 *a*) was very low (23°C) and accordingly the SST (Figure 9 *b*) also was

low (25°C). However, south of 17°N, conditions were warmer. Under the weak wind conditions, one would expect shallow MLD, as is the case during April–May. In contrast, the thermal structure showed deep MLD (Figure 9 c), specially north of 17°N in the open ocean. This suggests that the deepening of mixed layer in the north, during winter, is not due to wind but is driven by other atmospheric forcings.

In order to probe this further, we computed the heat and fresh water flux into the atmosphere (E–P) along 64°E. During winter the northern Arabian Sea (especially north of 10°N) experiences a net heat loss (about 140 Wm⁻²). This value is slightly lower than that of Hastenrath and Lamb¹⁰ which showed a net oceanic heat loss about 160 Wm⁻² from October to December. An examination of the climatological values¹⁰ of specific humidity during October (19 g kg⁻¹) and January (about 10 g kg⁻¹) in the northeastern Arabian Sea indicates the prevalence of dry air during winter. The cool dry continental air brought into the northern Arabian Sea by the prevailing north-east trade winds enhances evaporation, as evident from E–P values (Figure 9), leading to surface cooling. We estimated the cooling due to loss of heat to the atmosphere using the formula¹¹ $\Delta T = Q t / CM$ [where Q is the net heat flux to the atmosphere (Wm⁻²), t the time period (seconds) over which the heat flux occurs, C the specific heat of water (4.18×10^3 J kg⁻¹ K⁻¹) and M the mass (kg) of the water cooled], which works out to be about 3°C. Apart from the cooling due to evaporation, the decrease of solar insolation (net short wave radiation) from 220 Wm⁻² during October to about 160 Wm⁻² during January¹⁰ also contributes to the further cooling of the surface waters. Thus, in short the observed reduction in SST (by about 4°C) and deep MLD, in the northern Arabian Sea during winter is forced by a combination of enhanced evaporation and reduction in the solar insolation. In fact, this starts during December and persists till end of February. Accordingly, the northern Arabian Sea, north of 15°N, experiences cooling and densification (Figures 4 and 7). This leads to the formation of ASHSW¹², sinking and convective mixing; and injects nutrients into the surface layers from the

thermocline region, as is evident from the shoaling of 2 µM nitrate contour, which is seen at 30 m at 13°N and surfaced at about 17°N (ref. 13). In the Arabian Sea, nitrate in the surface layers is below detection level except during monsoonal upwelling. The nutrient injection to the upper layers of the water column triggers the primary productivity which was about 807 mg C m⁻² per day⁴. On the basis of coastal zone colour scanner data, Banse and McClain¹⁴ deduced the occurrence of highest pigment concentrations north of 20°N. The data presented here is the first ever observational evidence elucidating the physical forcing that brings about the winter bloom in the northern Arabian Sea.

Arabian Sea upwelling – A comparison between coastal and open ocean regions

P. M. Muraleedharan and S. Prasanna Kumar

National Institute of Oceanography, Dona Paula, Goa 403 004, India

The response of the eastern Arabian Sea to prevailing winds during an upwelling event, in the peak of southwest monsoon, was studied at both coastal and open ocean environment based on the data collected as a part of the Indian Joint Global Ocean Flux Studies (JGOFS) programme. Analysis of wind measurements indicated active upwelling along the southwest coast of India, which gradually propagates towards north. While the dominant long-shore component of the wind induces upwelling in the south, the cross-shore component is instrumental in modifying the density structure of the surface layer, especially in the north, to produce retarding effect. In open ocean, the wind maximum around 17° N and 64° E indicates the axis of the Findlater Jet. The observed surfacing and deepening of the isotherms on either side of the axis are the signatures of the upwelling and sinking associated with the Findlater Jet.

CLASSICAL explanation of coastal upwelling favours wind-induced divergence caused by Ekman transport of the surface water away from the coast¹. The concept is widely supported by observations^{2,3} as well as by theoretical models⁴⁻⁷. Although comprehensive literature on the coastal upwelling system in the Arabian Sea exists, information on open ocean upwelling is somehow scanty. Bauer *et al.*⁸ observed seasonal occurrence of wind-induced upwelling in the northern Arabian Sea, wherein considerable shoaling of the thermocline occurred under the region of maximum winds (Findlater Jet).

In the present paper we examine both coastal and open ocean upwelling during southwest monsoon season. To this end a cruise was undertaken during the peak of the southwest monsoon season (July–August 1995).

Data and methodology

The present investigation is based on the data collected onboard ORV *Sagar Kanya* from 20th July to 12th August 1995, as a part of the Indian Joint Global Ocean Flux Studies (JGOFS) Programme. A Sea Bird CTD was used to collect temperature–salinity profiles from 42 stations up to a maximum depth of 1000 m (Figure 1). Surface meteorological data were collected at six hourly interval along the track. Climatological

wind and sea surface temperature (SST) derived from Comprehensive Oceanographic and Atmospheric Data Set (COADS)⁹ and mixed layer depth (MLD) from Levitus data¹⁰ were also used for comparison with the *in situ* measurements.

Results and discussion

Wind field

The climatological wind during July indicates strong cross-shore component with positive trends from south to north and relatively weak long-shore component with similar trend, except at 15° N where a steep rise in wind speed is noticed (Figure 2a). The SST and MLD distributions also followed the same trend as the wind. It is hence inferred that an upwelling favourable condition existed along the southern shelf, which was less conspicuous towards north.

In the central Arabian Sea, along 64° E, both the zonal

Figure 1. Cruise track and station locations.

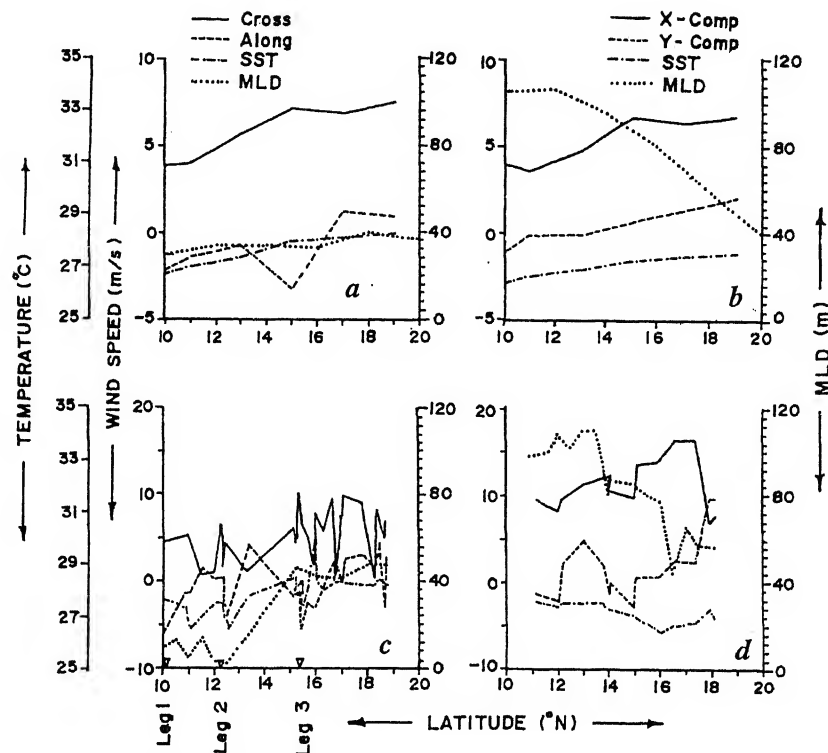

Figure 2 a-d. Variation of zonal and meridional wind component, sea surface temperature (SST) and mixed layer depth (MLD) from 10°N to 20°N along the west coast of India [climatological (a) and in situ (c)] and along 64° E [climatological (b) and in situ (d)] are plotted against latitude during July.

and the meridional components of the wind showed gradual increase from south to north (Figure 2 b). The zonal component was maximum around 17°N and decreased towards north. SST showed a gradual increase of 1°C from south to north. A thick MLD of 110 m was noticed at 10° N, which dropped to 40 m around 20° N. The high zonal component of the wind around 17° N represents the axis of the Findlater Jet. However, the climatological SST distribution does not imply an upwelling at the region of wind maximum.

In order to decipher the upwelling along the coast, *in situ* data were collected at three legs (Figure 1), viz. off Goa (15°N), off Mangalore (12.5°N) and off Cochin (10°N). The observed wind showed a steep rise in both cross-shore (positive towards east) and along-shore (negative towards south) components in all the three legs (Figure 2 c). High eastward wind component (10 ms⁻¹) was observed at leg 1 associated with moderately strong southward component (6 ms⁻¹). At leg 2 (off Mangalore) both eastward and southward components had the same magnitude of 4 ms⁻¹. However at leg 3 (off Cochin) the negative long-shore component (northerly wind) dominates over the positive cross-shore component (westerly wind),

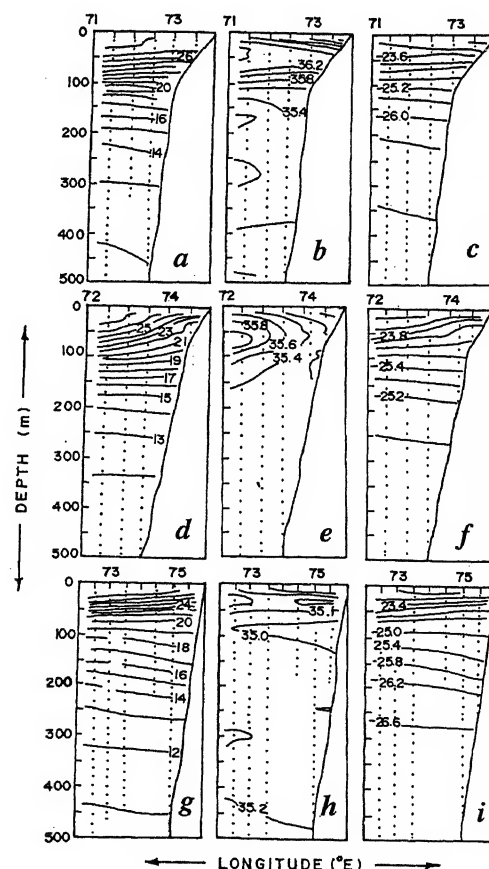

Figure 3 a-i. Vertical distribution of temperature (a, d, g), salinity (b, e, h) and density (c, f, i) along legs 1 (off Goa, top panel), 2 (off Mangalore, middle panel) and 3 (off Cochin, bottom panel).

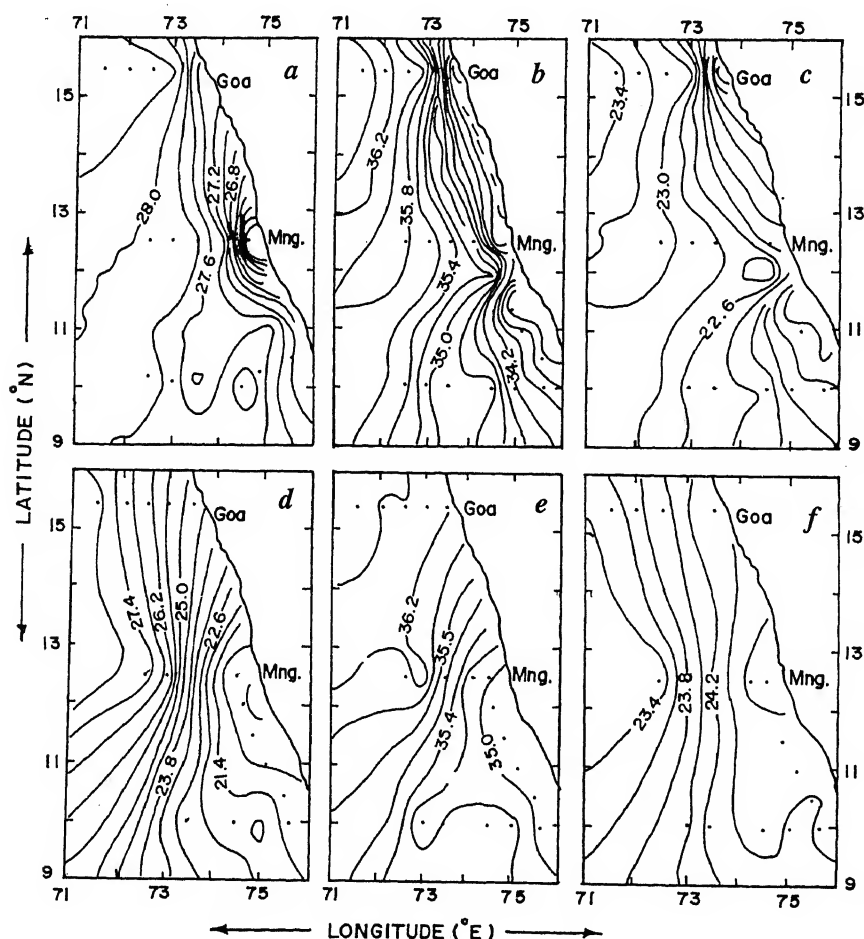

with their magnitudes exceeding 6 and 4 ms^{-1} , respectively (Figure 2 c). The shoaling of the isotherm with low SST off Cochin and Mangalore indicated strong upwelling, and were well correlated with the prevailing wind (Figure 2 c). Off Goa, though the along-shore wind component and the relatively low SST indicated divergence, the high value of MLD does not support the presence of an active upwelling. This is due to strong cross-shore wind present at this latitude, bringing the saline surface water towards the coast which modifies the density field to suppress upwelling. Thus it is obvious that both long-shore as well as cross-shore components play significant role in the dynamics of the underlying water column.

The observed wind and SST along 64°E differ considerably from the climatology, whereas the MLD distribution was consistent. Strong zonal wind component was noticed from 15°N to 18°N with weak meridional component (Figure 2 d). The wind maxima at 17°N (Findlater Jet) coincides with the lowest MLD value of 45 m . The remarkable shoaling of MLD from 100 m at 11°N to 45

m at 17°N was associated with active upwelling and sinking on either side of the wind maximum. This is consistent with the SST distribution where cool water is found at the zone of maximum wind and warm water southward.

Hydrographic field

The vertical thermal structure off Goa (Figure 3 a) exhibits gentle upsloping of isotherms towards the coast producing colder surface water. However, this trend is reversed in the sub-thermocline region and the isotherms were deepening towards the coast. Surface salinities near the coast were almost 0.8 PSU lower than the off-shore values (Figure 3 b). Below 200 m , however, there were no appreciable changes in the salinity. The down sloping of the isopycnals towards the coast indicated the dominance of salinity over temperature in the density field (Figure 3 c). This disappears in the sub-thermocline region where the distribution of density becomes analogous to that of temperature. The isopycnals at the sub-thermocline depth also followed the same

trend as the temperature. This feature was more conspicuous at the 200 m depth.

The nearshore values of SST off Mangalore were much lower ($<23^{\circ}\text{C}$) when compared to the offshore values ($>27^{\circ}\text{C}$) with a gradient of 0.01°C per km (Figure 3 d). The remarkable shoaling of thermocline towards the coast is an indication of the active upwelling which is again reflected in the density distribution (Figure 3 f). Salinity near the coast was as low as 35 PSU (Figure 3 e). Deepening of isotherms and isopycnals at the sub-thermocline depth is noticed at this latitude also.

Although the SST off Cochin did not show any appreciable change, the subsurface isotherms above 100 m did indicate gentle upward sloping towards the coast (Figure 3 g). The deepening of isotherms and isopycnals in the sub-thermocline region is more pronounced at this latitude (Figure 3 g & i). The salinity section, in general, does not have any commendable features (Figure 3 h).

The strong thermal front identified off Mangalore, from the horizontal temperature field, is the manifestation of an

active upwelling system (Figure 4 a). Similar features were not observed off Goa and Cochin. The high salinity tongue near Goa and Mangalore was an indication of on-shore transport of surface water as a result of the prevailing winds (Figure 4 b). The surface density distribution showed the occurrence of lighter water along the shelf and denser water off-shore (Figure 4 c). The thermal gradient at 50 m was three times higher than the surface value with gradient greater than 0.03°C per km (Figure 4 d). The intrusion of high salinity water from the central Arabian Sea, as observed at the surface, was less conspicuous at this depth (Figure 4 e). The lateral density distribution reversed with denser water along the coast and lighter water off-shore (Figure 4 f). The temperature field at 100 m depth is dominated by eddy-like circulation (Figure 5 a). Penetration of high salinity water from north was seen as a well-developed tongue at this depth (Figure 5 b). There was not much lateral variation in density (Figure 5 c). At 200 m, the thermohaline structure was entirely different from that at 100 m (Figure 5 d and e). However, a re-

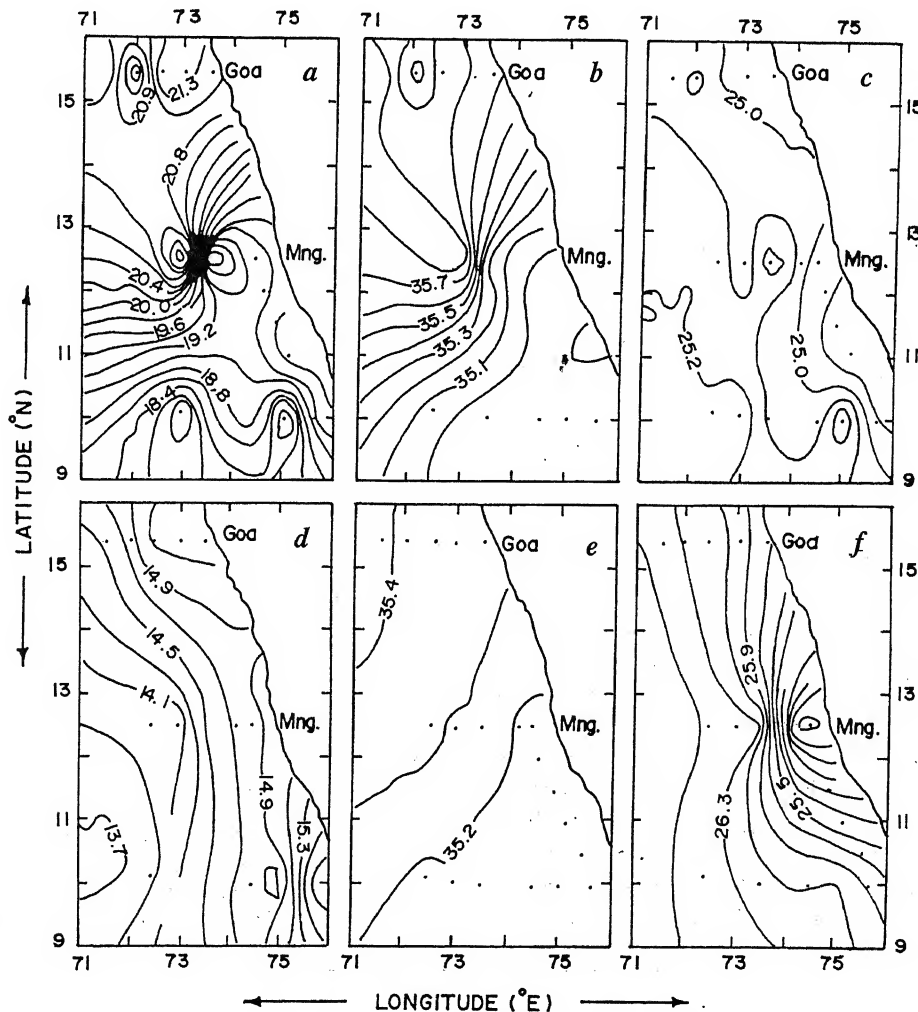

Figure 5 a-f. Horizontal distribution of temperature (a), salinity (b), and density (c) at 100 m and at 200 m (d, e, f, respectively).

Figure 6. Vertical distribution of temperature (a), salinity (b), and density (c) along 64° E.

versal of lateral density distribution was observed again at this depth with relatively stronger gradient near Mangalore (Figure 5f).

Along 64°E, the shoaling of the isotherms above 150 m was a direct indication of open ocean upwelling north of 14°N (Figure 6a), while the deep MLD (110 m) towards south was associated with sinking. The high salinity core observed at 300 m around 18°N was the Persian Gulf water (PGW) mass, which spreads southward. Below 200 m, both temperature as well as salinity structure showed sinking, resulting in a vertically homogeneous salinity structure (Figure 6b). However, the density structure was analogous to that of temperature in the upper 150 m layer. In the sub-thermocline depth, density structure differed from that of temperature due to the proximity of PGW.

In summary, the wind field along the south west coast of India favoured strong upwelling off Cochin, less strong off Mangalore and relatively weak off Goa. Hydrography also supported this, except off Cochin where data close to the coast were not adequate to make the comparison. The stronger subsurface upwelling front (thermal) in comparison to the surface (the gradient of which was three times the surface value) indicates that the regional dynamics suppresses the surface divergence. A plausible explanation could be sought from the prevailing wind forcing. The cross-shore component of the wind pushes the surface high salinity water (ASHSW) towards the coast which modifies the density field along the shelf and suppresses the Ekman pumping mechanism. In the sub-thermocline depth (200 m) the density distribution indicated the pres-

ence of a coastal undercurrent which is consistent with the earlier studies^{11,12}. The eddy-dominated circulation seen at the bottom of the thermocline (100 m) is the manifestation of frontal instability at the interface between the surface coastal current and the subsurface undercurrent. The open ocean upwelling occurs under the influence of the Findlater Jet, the axis of which was located at 17°N, towards the north while sinking to the south.

Seasonal variability in oxygen and nutrients in the central and eastern Arabian Sea

S. N. de Sousa, M. Dileep Kumar, S. Sardesai, V. V. S. S. Sarma and P. V. Shirodkar

National Institute of Oceanography, Dona Paula, Goa 403 004, India

Extensive observations made in the central and eastern Arabian Sea under JGOFS (India) programme suggest strong seasonal variations in concentrations of oxygen and nutrients in the water column. In the intermediate waters (depth range 150–800 m) oxygen concentrations were lowest during winter (with values near zero at ~400 m) in relation to those in the other two seasons (intermonsoon and southwest monsoon). This together with nitrate distributions revealed the occurrence of intense reducing conditions in intermediate waters during winter because of the sluggish water movement and high surface productivity. Secondary nitrite, an indicator of occurrence of denitrification was present at oxygen levels $< 10 \mu\text{M}$. Nitrate deficits reached a maximum of $10 \mu\text{M}$ in winter, whereas, it was half this value in monsoon. The average deficits suggest increasing reducing conditions in the order monsoon ($1.6 \mu\text{M}$), intermonsoon ($3.7 \mu\text{M}$) and winter ($4.0 \mu\text{M}$).

THE Indian Ocean experiences seasonally variable surface circulation. During the southwest monsoon, upwelling occurs along the east coasts of north Africa and Arabia^{1,2} and the southwest coast of India^{3,4}. This results in high biological production, making the Arabian Sea one of the most productive areas in the world oceans⁵. High biological production and subsequent sinking of organic matter leads to high oxygen demand in intermediate waters. Although the renewal of intermediate waters is quite rapid^{1,6}, this high demand leads to the development of intense oxygen minimum at intermediate depths where oxidized nitrogen species are reduced to molecular nitrogen^{6–11}. Denitrification in the Arabian Sea is estimated to be about 1/3 of the global ocean denitrification⁶ which has been shown to vary between northeast (winter) and southwest (summer) monsoon seasons with higher nitrate deficits during the former¹². In this article we report the seasonal variability in reducing conditions in intermediate waters and the influence of physical processes, such as upwelling and winter convection, on the property distributions using the data collected as a part of the JGOFS (India) programme.

Data sets used were collected in the central and eastern Arabian Sea water column during the ORV *Sagar Kanya* cruises SK-91 (April–May), SK-99 (February–March) and SK-104 (July–August) representing the

intermonsoon, winter and southwest monsoon periods, respectively. During the SW monsoon, samples could be collected only up to 18°N . Figure 1 shows the cruise tracks. Water samples were collected using a Seabird CTD rosette, fitted with 12 Niskin bottles of 1.8/12/30 litre capacity. Dissolved oxygen was measured by Winkler titration during SK-91, and by spectrophotometric method¹³ during SK-99 and SK-104. The spectrophotometric measurement of oxygen improved the precision significantly, particularly at low oxygen levels (at $4 \mu\text{M}$ it is $\pm 0.1 \mu\text{M}$). The analyses of nitrite, nitrate and silicate were done using a Skalar Analyser 5100/1. Phosphate was measured spectrophotometrically using the method of Murphy and Riley¹⁴.

The distribution of oxygen in the upper 1000 m during the three seasons is shown in Figure 2. The data show the lowest oxygen concentrations in winter. Its minimum reached near-zero levels during this season while in monsoon it was $\sim 15 \mu\text{M}$. The distribution of nitrate during the three sampling periods is shown in Figure 3. The surface waters were devoid of nitrate during the intermonsoon period. In winter nitrate was about $2 \mu\text{M}$ in the surface waters of northern latitudes, result-

Figure 1. Map showing cruise tracks.

Figure 2. North-south variations in dissolved oxygen (μM) along 64°E ; contours shown for levels $< 30 \mu\text{M}$ only.

ing from wintercooling and convective mixing^{15,16}. These data are consistent with primary productivity measurements during these two seasons^{16,17}. In monsoon there is a conspicuous high nitrate patch in surface waters at about 16°N (Figure 3). This patch is also characterized by lower temperature and higher oxygen concentrations, signatures of upwelling, resulting from gyral circulation¹⁸ or wind regime of Findlater jet¹⁹. The depth profiles of nitrate in general show that, at any given depth the concentrations were lower in the northern latitudes. This probably results from the consumption of nitrate in these regions for combustion of organic matter. Due to enhanced surface productivity in winter, the large amounts of organic matter should be oxidized in intermediate layers, thus leading to oxygen-deficient conditions. When the oxygen is present at trace levels, the bacteria utilize nitrate as oxidant for the decomposition of organic material. During this process nitrate gets reduced to elemental nitrogen as the end product with nitrite as an important intermediate. Thus the presence of nitrite below the thermocline indicates the occurrence and the intensity of denitrification process.

Figure 4 is a plot of nitrite and oxygen in monsoon

Figure 3. North-south variations in nitrate (μM) along 64°E .

and winter observed in samples from surface to 1000 m. The data show that there are two distinct ranges of oxygen levels in winter where nitrite was present. One is near the upper thermocline region with oxygen concentrations of $175\text{--}275 \mu\text{M}$ and the other is in intermediate depths with oxygen $< 10 \mu\text{M}$. Such distinction could not be made for monsoon since the oxygen in subsurface layers is also relatively high. While nitrite present in sub-oxic waters indicates the occurrence of denitrification, that in the thermocline region originates from nitrification process⁷. Data for monsoon (inset) suggest that secondary nitrite can occur in the presence of trace levels ($5\text{--}10 \mu\text{M}$) of oxygen. However, the oxygen has been reduced further during winter mainly because of its enhanced consumption triggered by the rain of organic matter from surface layers.

The estimated nitrate deficit⁷ (DELN), a measure of nitrate decrease due to its reduction to molecular nitrogen, ranged from 0 to $10 \mu\text{M}$ in the waters between 100 and 1000 m. The highest DELN values were found in winter, particularly in the north (Figure 5) with clearly discernible north-south gradients. In the intermonsoon period, the high DELN values were found at $\sim 14^\circ\text{N}$ be-

cause of relatively low nitrate pocket observed at ~200 m. In monsoon, in spite of the relatively high oxygen in intermediate waters, DELN reached a value

of ~5 μM . This indicates that the Arabian Sea experiences denitrification in all the seasons but its extent is variable. This is obvious from Figure 6 which shows

Figure 4. Relation between dissolved oxygen (μM) and nitrite (μM) during monsoon and winter.

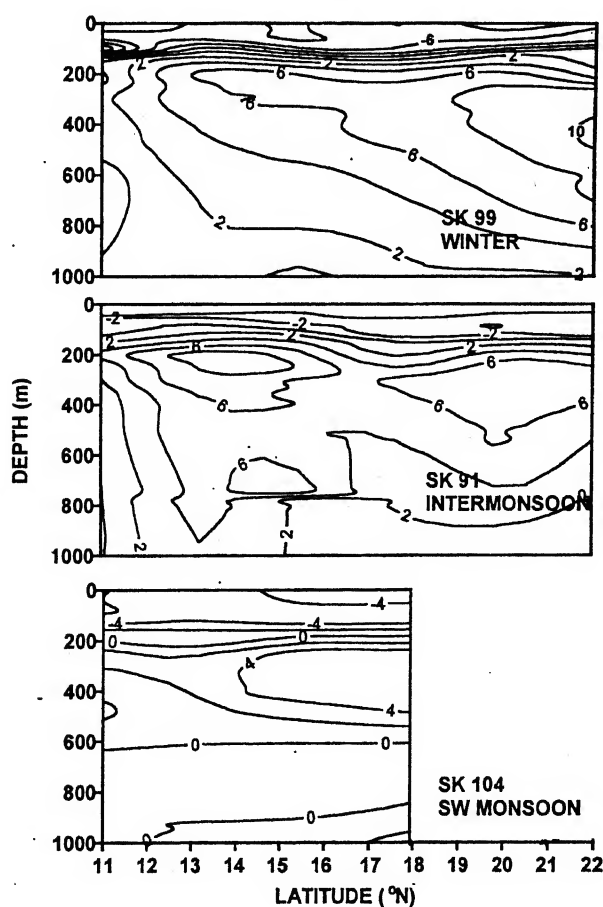

Figure 5. North-south variations in nitrate deficit (DELN, μM), along 64°E.

Figure 6. Dissolved oxygen (at $<60 \mu\text{M}$) versus DELN (μM) during different seasons along 64°E .

the relationship between dissolved oxygen and DELN; for O_2 concentration $\leq 60 \mu\text{M}$ for different seasons. A large number of points have positive DELN values in winter particularly below $10 \mu\text{M}$ of oxygen. This is in good agreement with that of nitrite (Figure 4).

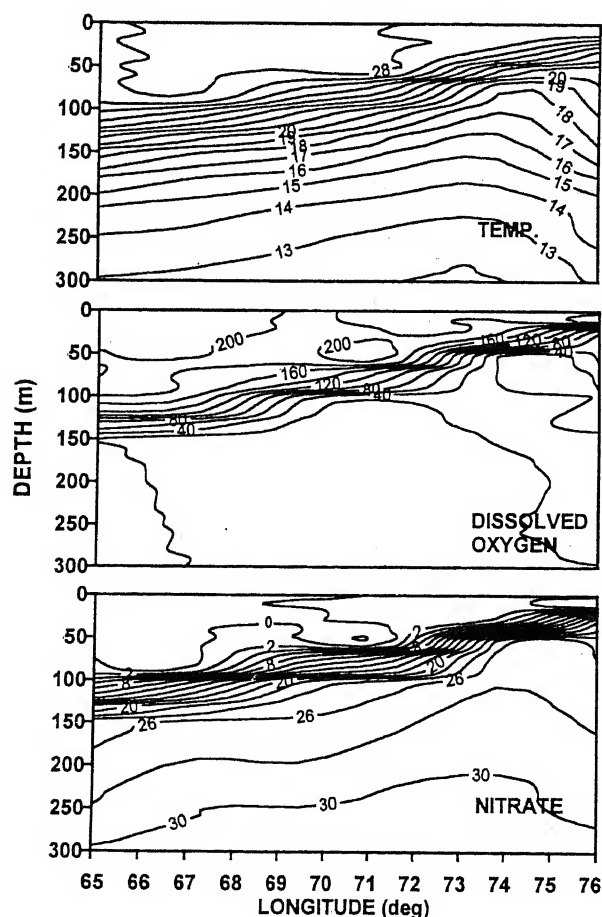

Figure 7. East-west distribution of temperature ($^\circ\text{C}$), oxygen (μM) and nitrate (μM) during SW monsoon.

During winter, convective mixing facilitates the upward pumping of nutrients-laden subsurface layers^{15,16}. Figure 3 shows the influence of this winter mixing on nutrient pumping; the nitrate isoline of $2 \mu\text{M}$ surfaced in the northern latitudes. This process is more vigorous in the northeastern region of the Arabian Sea where the mixed layer deepens to $\sim 100 \text{ m}$, leading to relatively higher biological production. For instance, in winter¹⁷ the primary production was $807 \text{ mgC m}^{-2} \text{ d}^{-1}$ at 21°N and 67°E while it was $335 \text{ mgC m}^{-2} \text{ d}^{-1}$ at 11°N and 64°E about a factor or two higher than that during the intermonsoon season; 310 and $163 \text{ mgC m}^{-2} \text{ d}^{-1}$ at these stations, respectively¹⁷. Hence, the observed variations in nitrate (Figure 3) and total carbon dioxide²⁰ abundances are in agreement with the gradients in productivity. The high surface primary production¹⁷ together with the sluggish renewal of intermediate waters^{1,12} could have resulted in the intense reducing conditions in winter (Figure 5).

Intense upwelling occurs in the northwestern Arabian Sea but of moderate intensity along the southwest coast of India^{4, 21,22}. In addition to that shown in Figure 3, Figure 7 depicts the signatures of upwelling in the eastern side of the east-west section in Figure 1. This occurred to the east of 72°E where the surface temperatures were less than 28°C . The effect could also be

Table 1. Average values of oxygen and nitrate deficit (DELN) in denitrification zone and surface Chlorophyll *a* in the Arabian Sea

Season	Cruise no.	Oxygen (μM)	DELN (μM)	Chl (mg m^{-3})
Intermonsoon	SK 91	17.5	3.72	8.3
Winter	SK 99	10.6	4.02	20
Southwest monsoon	SK 104	18.2	1.62	—

seen in nitrate distribution but not in dissolved oxygen (Figure 7). Increases in nutrients in surface layers due to upwelling result in increased productivity. For example, the primary productivity was $1760 \text{ mgC m}^{-2} \text{ d}^{-1}$ off Mangalore ($12^{\circ}30' \text{N}$, $73^{\circ}30' \text{E}$), $660 \text{ mgC m}^{-2} \text{ d}^{-1}$ near Cochin (10°N , $75^{\circ}35' \text{E}$) and $440 \text{ mgC m}^{-2} \text{ d}^{-1}$ off Bombay¹⁷. This shows a patchiness in surface production. The intensity of upwelling along the southwest coast of India can be suppressed by land run-off^{4,21}. Consequently, variable run-off may have caused the observed patchiness in productivity⁴. However, during intermonsoon it was $199 \text{ mgC m}^{-2} \text{ d}^{-1}$ near Cochin¹⁷ which is considerably less than that in monsoon.

Table 1 shows the seasonal variability in average redox conditions (oxygen and nitrate as indicators) in the Arabian Sea. These are averages for the zone of denitrification, i.e. positive DELN. Results indicate relatively lower dissolved oxygen ($11 \mu\text{M}$) with relatively high DELN ($4 \mu\text{M}$) during winter. This is consistent with the average abundance of chlorophyll *a*. Although the oxygen levels between intermonsoon and monsoon did not differ greatly, the nitrate deficit during the former season was nearly twice that computed for monsoon.

ACKNOWLEDGEMENTS. We thank the Director, NIO, for support. The Department of Ocean Development, Govt. of India provided financial support for the studies under the JGOFS (India) programme. We are also grateful to Prof. S. Krishnaswami and Drs S. W. A. Naqvi and C. T. A. Chen for their constructive suggestions. This is NIO contribution no. 2505.

Seasonal variations in inorganic carbon components in the central and eastern Arabian Sea

V. V. S. S. Sarma, M. Dileep Kumar, M. D. George and A. Rajendran

National Institute of Oceanography, Dona Paula, Goa 403 004, India

Extensive observations have been made on the carbon dioxide system in the Arabian Sea during three different seasons as part of the Indian Joint Global Ocean Flux Study (JGOFS) Programme. Concentrations of total carbon dioxide and partial pressure of carbon dioxide exhibited seasonal variability, with pronounced north-south gradients in surface layers. Total carbon dioxide in surface waters was higher by $\sim 100 \mu\text{M}$ during winter compared to the intermonsoon period due to winter cooling and convective mixing. The partial pressure of carbon dioxide ($p\text{CO}_2$) in surface layers was generally in excess over the atmospheric value, suggesting that the central and eastern Arabian Sea is a perennial source to atmospheric carbon dioxide. The flux of carbon dioxide to atmosphere reached a maximum of $\sim 40 \text{ mmole m}^{-2} \text{ d}^{-1}$ around 16°N in the central Arabian Sea during monsoon season. The carbon dioxide regenerated from soft tissue was higher during winter and is the least in monsoon. The aragonite saturation horizon occurred around 500 m.

THE northwestern Indian Ocean (Arabian Sea) is a region of negative water balance where evaporation far exceeds precipitation and run-off. Consequently, the upper layers in the region are more saline and weakly stratified¹. This region, strongly affected by seasonal changes associated with monsoon, is one of the most productive areas of the world oceans². The northwestern Arabian Sea is more affected by these changes since intense upwelling occurs in this region during the southwest monsoon season. The northeastern Arabian Sea, on the other hand, experiences winter cooling and convective mixing resulting in the upward transport of nutrients³. These processes make the Arabian Sea important with respect to air-sea exchange of biogenic gases. Carbon dioxide is estimated to be released to the atmosphere at a rate of $74\text{--}79 \text{ Tg C yr}^{-1}$ from this region^{4,6}. Intense oxygen-deficient conditions develop within intermediate layers in the north because of oxidation of large amounts of organic matter that leads to nitrate consumption through denitrification^{7,8}. This results in reducing conditions in the Arabian Sea that could influence the carbonate equilibria and raise the partial pressure of carbon dioxide ($p\text{CO}_2$) in water. Here, we present results of extensive measurements

on carbon dioxide components made as a part of JGOFS (India) programme, in the central and eastern Arabian Sea and discuss their seasonal and spatial variability.

The measurements were made during intermonsoon (SK 91; April to May), winter (SK 99; February to March) and southwest monsoon (SK 104; July to August) seasons on board ORV *Sagar Kanya*. A Seabird CTD rosette system fitted with 1.8/12/30 litre Niskin bottles was used to collect water samples. Sub-samples were drawn into 125 ml stoppered glass bottles taking due care to avoid trapping of air bubbles. All analyses were completed within 24 hours of the collection. Oxygen analyses were done by Winkler's titration during SK 91 while it was done by spectrophotometry on SK 99 and SK 104. Total carbon dioxide (TCO_2) was measured using a Coulometer (Model 5011 of UIC Inc., USA) following the procedure detailed elsewhere⁶ but with a semi-automated sample drawing system. The pH was measured by multiwavelength spectrophotometry at 25°C using Cresol red indicator⁹. The measured pH, on free ion scale, was converted to pH on total scale as described in George *et al.*⁶. Ionization constants of carbonic acid were computed using the relations of Goyet and Poisson¹⁰. Analytical precisions for TCO_2 and pH are $\pm 2.0 \mu\text{M}$ and ± 0.002 , respectively, while those for the calculated parameters, $p\text{CO}_2$ and CO_3^{2-} , are $\pm 4.0 \mu\text{atm}$ and $\pm 1.7 \mu\text{M}$, respectively. The accuracy of TCO_2 measurements was checked using the Certified Reference Materials supplied by Dr A. G. Dickson of Scripps Institution of Oceanography, USA, and was found to be 0.2–0.3%. The carbon dioxide fluxes were computed according to Wanninkhof¹¹ using the measured wind speeds.

The surface TCO_2 concentrations were the highest in winter and are comparable in monsoon and intermonsoon (Figure 1). The north-south gradient is clearly seen in the intermonsoon and winter seasons where sampling could be done from 11° to 22°N . The presence/absence of such a trend during monsoon could not be ascertained as sampling was restricted to $11^\circ\text{--}18^\circ\text{N}$. However, during monsoon there was a patch of low TCO_2 in surface waters around 16°N (Figure 1) which may be related to upwelling driven by the Findlater Jet¹² or to a gyral circulation¹³. In intermediate layers the TCO_2 levels were higher at all depths in the north than

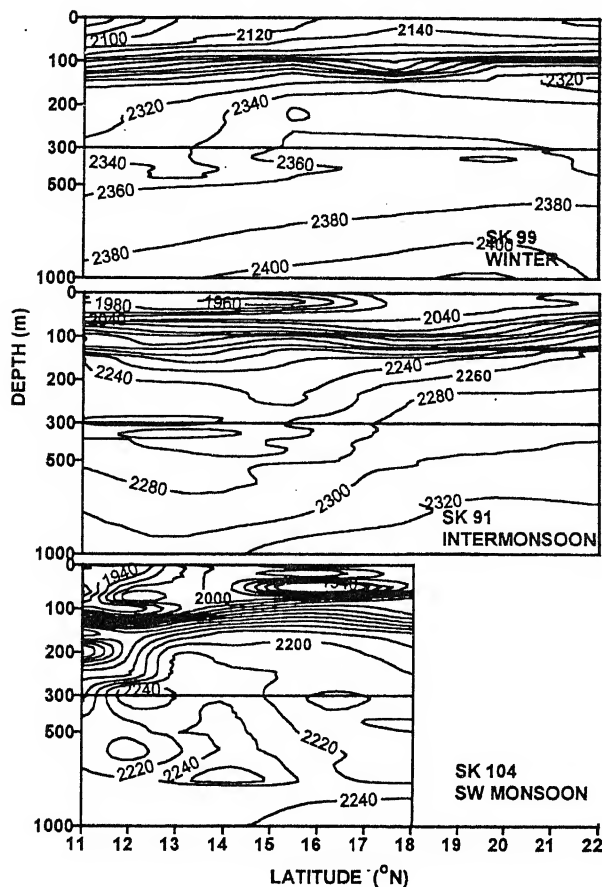

Figure 1. Distribution of TCO_2 (μM) along 64°E during three different seasons winter, intermonsoon and southwest monsoon in the Arabian Sea.

those in the southern Arabian Sea during winter and intermonsoon seasons. This results from a combination of higher biological production, and the consequent regeneration processes and aging of subsurface waters towards the north. The seasonal trends in deep TCO_2 concentrations are consistent with those observed in surface layers. This is because of the fact that the increased surface TCO_2 shall be associated with the supply of nutrients from thermocline region that could enhance production in the upper layers. The subsequent sinking and regeneration of this material in the subsurface layers would lead to proportional increase in TCO_2 . The differences in TCO_2 have, however, decreased from $\sim 100 \mu\text{M}$ in the upper layers to $\sim 80 \mu\text{M}$ around 1000 m between winter and intermonsoon. The seasonal gradients in TCO_2 agreed well with the nitrate distribution shown by de Sousa *et al.*¹⁴. The nitrate concentrations were less than expected from the general trends and consequently nitrate deficit was significant in winter than that in intermonsoon. This larger nitrate deficit is caused by enhanced decomposition of sinking organic material, following higher surface production¹⁵ in winter. The salinity distribution in intermediate layers (Figure 2) indicated increased influence of Persian Gulf Water (PGW),

farther south, in southwest monsoon compared to other seasons. This could be due to seasonal variations in the distribution of outflowed PGW in the Arabian Sea. For instance, the wind fields suggest that the PGW outflow might be carried along the western Arabian Sea in winter but along the eastern part in monsoon (Dr S. Prasanna Kumar, pers. comm.). The PGW is relatively depleted in TCO_2 with $\sim 2150 \mu\text{M}$ (ref. 16) compared to that in intermediate waters of even the south Arabian Sea. Hence, comparatively low TCO_2 was observed in monsoon in intermediate layers of the Arabian Sea due to dilution by PGW. This is augmented by Figure 3, where PGW (rich in oxygen with $\sim 190 \mu\text{M}$) leads to relatively higher oxygen concentrations ($\sim 50 \mu\text{M}$) in monsoon compared to those in winter in subsurface waters of the Arabian Sea.

The higher average TCO_2 ($>2120 \mu\text{M}$) levels in surface waters north of 16°N , during winter, can be attributed to winter cooling and convective overturning³. On the other hand, relatively higher TCO_2 at shallower depths also occurred in waters off the southwest Indian coast during monsoon. This is due to upwelling induced by the prevailing winds^{12,17} that results in the shoaling of 27°C isotherm from 100 m at 64°E to about 10 m at

Figure 3. Variation in oxygen between winter (SK 99) and monsoon (SK 104) at 16° N.

76° E (Figure 4). Similarly, isolines of pH (8.00) and TCO_2 (2000 μM) became progressively shallow towards the east which also is the case with pCO_2 (Figure 4). However, there was a large variation in surface TCO_2 along this section that parallels the eastward decrease in salinity, due to the influx of fresh water with lower TCO_2 from land.

Relatively low pH values are observed in the northern Arabian Sea than elsewhere in the North Indian Ocean due to prevailing reducing conditions in the

former region⁶. The depth distribution of pCO_2 (calculated from the measured TCO_2 and pH) is shown in Figure 5 that essentially conform with pH trends. The pCO_2 values in surface waters were generally higher than that in the atmosphere; they mostly centered around ~420 μatm in winter, but with a range of 360–420 μatm during the other two sampling periods. This is again a result of high surface production in winter that subsequently leads to higher pCO_2 levels in subsurface layers. The relatively higher subsurface pCO_2 seems to have been transported into the surface effectively by winter convection. The pCO_2 increased to 1100 ± 100 μatm in intermediate waters (200–1000 m) with discernible seasonal variations (Figure 5). In general pCO_2 in the intermediate waters was higher during winter compared to other two seasons. A patch of high pCO_2 surface water was observed during the monsoon at ~16°N. This results from the offshore upwelling and also from the build up of carbon dioxide partial pressure in intermediate layers in the north. This differential gradient of pCO_2 between subsurface and surface layers drives relatively more carbon dioxide into the surface layers in the north in general. The calculated average carbon dioxide fluxes from sea to air around 21°N and 11°N were about 13 and 0.21 $\text{mmol m}^{-2} \text{d}^{-1}$ in intermonsoon and 1.2 and 0.3 $\text{mmol m}^{-2} \text{d}^{-1}$ during winter, respectively. In monsoon, the flux was about 40 $\text{mmol m}^{-2} \text{d}^{-1}$ around 16°N in the Arabian Sea, where a gyral upwelling was noticed, while it was ~8 $\text{mmol m}^{-2} \text{d}^{-1}$ in the south. Although the fluxes during intermonsoon were as expected from the north-south gradient in regeneration intensities those in win-

Figure 4. Distribution of temperature (°C), pH, TCO_2 (μM) and pCO_2 (μatm) along an east-west section around 10–11° N.

Figure 5. Distribution of $p\text{CO}_2$ (μatm) along 64°E during three different seasons: winter, intermonsoon and southwest monsoon in the Arabian Sea.

ter were not proportional since the evaluated fluxes depend on prevailing wind speeds as well. We observed higher north-south gradients in wind speeds in intermonsoon than in winter. Our results thus reveal that the central and eastern Arabian Sea serves as a perennial source of CO_2 to the atmosphere.

Regenerated carbon (Figure 6) was also found to behave similar to that of TCO_2 (Figure 1). During winter it is higher by $70\text{--}80\ \mu\text{M}$ than in intermonsoon and by more than $100\ \mu\text{M}$ compared to that in monsoon. The regenerated carbon dioxide was evaluated, following the generalizations made for global oceans¹⁸, from

$$\text{TCO}_2(\text{n}) = (\text{TCO}_2 * 35.000)/S$$

$$\text{TCO}_2(\text{pre})(\text{n}) = 2233 - 10.36 * \theta$$

$$\text{TCO}_2(\text{reg}) = \text{TCO}_2(\text{n}) - \text{TCO}_2(\text{pre})(\text{n}),$$

where suffixes 'n', 'pre' and 'reg' indicate normalized, predicted and regenerated components, respectively. θ is the potential temperature. The regeneration amounted to a CO_2 release of $140\ \text{mM}$ at $200\text{--}300\ \text{m}$ in intermonsoon whereas it was about $80\ \mu\text{M}$ and $230\ \mu\text{M}$, respectively, during monsoon and winter seasons

(Figure 6).

The regional variability in calcium carbonate saturation was studied with respect to calcite and aragonite. Saturation carbonate ion concentrations were estimated following the equations of Mucci¹⁹ for the effects of temperature and salinity and of Millero²⁰ for the influence of pressure on the solubility products of aragonite and calcite. Surface waters of the northern Indian Ocean have been found to be supersaturated with respect to both calcite and aragonite^{5,6,21,22}. The present computations suggest that a change-over from supersaturation to undersaturation of aragonite occurs around $500\ \text{m}$ while it is $\sim 2000\ \text{m}$ for calcite in the northern Arabian Sea. But the southern Arabian Sea ($\sim 11^\circ \text{N}$) is supersaturated even at $3000\ \text{m}$ with respect to calcite. The present observations support the view that the deep northern Arabian Sea is relatively more corrosive to carbonate skeletal materials than the southern part^{5,6}.

This study thus establishes a strong seasonal variability in CO_2 components in the Arabian Sea. The TCO_2 and $p\text{CO}_2$ are higher in winter and are driven by cooling

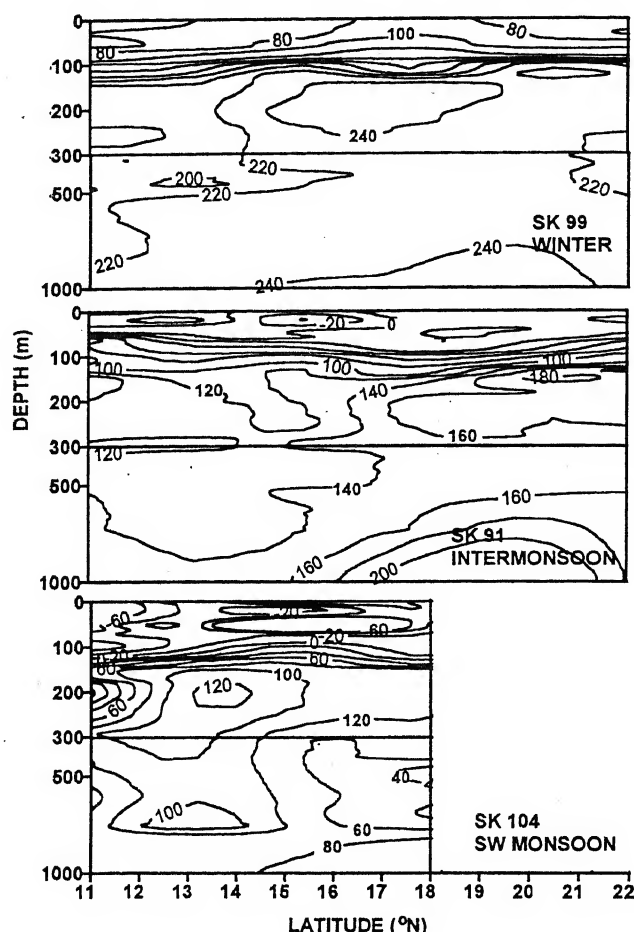

Figure 6. Distribution of regenerated CO_2 (μM) along 64°E during three different seasons winter, intermonsoon and southwest monsoon in the Arabian Sea.

and convective mixing. Intense winds cause larger sea-to-air exchange of CO_2 to atmosphere. The CO_2 regeneration is also intense in winter.

ACKNOWLEDGEMENTS. We thank the Director, NIO, for providing facilities and support. The JGOFS (India) Programme has been funded by the Department of Ocean Development, Government of India, New Delhi. We appreciate the efforts of Prof. S. Krishnaswami in co-ordinating the JGOFS (India) Programme and Drs S. W. A. Naqvi and C. T. A. Chen for their constructive comments on the manuscript. This is NIO contribution no. 2506.

Phytoplankton production and chlorophyll distribution in the eastern and central Arabian Sea in 1994–1995

P. M. A. Bhattathiri, Aditi Pant*, Surekha Sawant, M. Gauns, S. G. P. Matondkar and R. Mohanraju

National Institute of Oceanography, Dona Paula, Goa 403 004, India

*National Chemical Laboratory, Pune 411 008, India

Measurements of primary production, chlorophyll *a*, particulate organic carbon (POC) and nitrogen (PON) were carried out during the inter-monsoon, winter monsoon and summer monsoon seasons of 1994–95 in the central and eastern Arabian Sea. The integrated production rate varied between 193–199, 337–643 and 770 $\text{mgCm}^{-2} \text{d}^{-1}$ respectively in the open ocean (along 64°E) for the three seasons. The corresponding values in near coastal stations were 281–306, 200–807 and 440–1760 $\text{mgCm}^{-2} \text{d}^{-1}$. Column chlorophyll *a* values for these seasons were between 8–17, 13–27 and 34–44 mgm^{-2} in the open ocean and 11–12, 10–34 and 16 to 88 mgm^{-2} for near coastal waters. A subsurface chl maximum (SCM) at ~40–60 m was conspicuous during the intermonsoon period. The seasonal variation in productivity was consistent with the circulation patterns and associated nutrient levels. Phytoplankton and zooplankton (as carbon) contributed 10–22% of POC. Estimated division rate of phytoplankton varied from 0.7 to 3 for different seasons and locations.

INFORMATION on the primary production and chlorophyll is available to a reasonable extent from the northern regions of the Arabian Sea^{1–7}. In recent years renewed interest in the region has been generated as part of the Joint Ocean Global Flux Study to assess the role of the oceanic regions as a source or sink of atmospheric CO_2 on a global context. The aim of this work was to obtain the rate of phytoplankton production and biomass in different seasons and examine the spatial variations. Data obtained during three cruises are presented in this article.

Materials and methods

Sampling was carried out onboard ORV *Sagar Kanya* during April–May 1994 (inter-monsoon), February–March 1995 (winter monsoon) and July–August 1995 (summer monsoon) (Figure 1). Water samples were collected from eight depths (0, 10, 20 m and then every 20 m up to 120 m) using 12 litre Go FLO samplers attached to the plastic coated winch wire. Water samples

from each depth were transferred to 5 Nalgene PC bottles⁸ of 300 ml capacity. 185 kbq of radioactive carbon (^{14}C) in 1 ml of aqueous solution was added to each of the PC bottles (^{14}C was obtained from BRIT, Department of Atomic Energy). To determine the initial activity in the bottles, 0.2 ml from one of the bottles was transferred to a scintillation vial and 0.2 ml of ethanolamine was added to it. 100 ml from one of the bottles was filtered on to 25 mm GF/F (nominal pore size $0.7 \mu\text{m}$) filter paper for determining the initial adsorption of the ^{14}C by the particles in the bottle. From the remaining four bottles from each depth, one was covered with aluminium foil and transferred to a black bag to determine the dark production. Thus, one dark and 3 light bottles were used from each depth for *in situ* in-

cubation. The bottles were later suspended at appropriate water depths using polypropylene line attached to a buoy. The system was deployed approximately one hour before sunrise, and was retrieved half an hour after sunset. Upon retrieval, the samples were filtered on to GF/F filters and the filters were transferred to scintillation vials to which 0.25 ml of 0.5 N HCl was added and held at room temperature until later analysis. In the shore laboratory sample vials were left uncapped overnight to dry. Liquid scintillation cocktail was added to the vials and after about a day, during which time the scintillation were stabilized, they were counted in a Packard 2500 TR liquid scintillation system. The counted rates were converted to daily production rates ($\text{mgCm}^{-3}\text{d}^{-1}$). The production rates obtained from the triplicates generally agreed within $\pm 10\%$ and averaged to obtain mean values for a given depth (Table 1). Dark bottle production rate was subtracted from the mean rate of light bottle to correct for non-photoautotrophic carbon fixation or adsorption. The daily production rate of various depths was used to calculate the water column integrated production ($\text{mgCm}^{-2}\text{d}^{-1}$).

Chlorophyll *a* was determined by filtering one litre of water samples from each depth using 47 mm GF/F filters (nominal pore size 0.7 μm) under low vacuum (less than 100 mm Hg). The chlorophyll was extracted using 10 ml of 90% acetone (AR) in the dark for 24 hours in a refrigerator. Samples are brought to room temperature and the fluorescence was measured in a Turner Designs Fluorometer before and after acidification with two drops of (1.2N HCl) acid⁸. The chlorophyll *a* was calcu-

lated from the fluorescence using the appropriate calibration factor. The value from each depth was integrated to obtain the column concentration. The instrument was calibrated with pure Chl *a* (Sigma) before the cruise.

For the measurements of suspended particulate organic carbon (POC) and nitrogen (PON), 3 litres of water samples from each depth was filtered on to precombusted 47 mm GF/F filters (nominal pore size 0.7 μm). The filter is removed, wrapped in precombusted aluminium foil and stored frozen in a deep freezer (-20°C) before analysis⁸. Later filters were dried overnight at 60°C . The dried filters were exposed to fuming HCl to remove inorganic carbonate. The filters dried again at 60°C were divided equally into four sections and analysed for POC and PON samples on a Perkin Elmer 2400 CHN analyser. Standards and blanks were run before analysis of samples.

Results

During the inter-monsoon period the surface primary production varied from 0.7 to $11.9 \text{ mgCm}^{-3}\text{d}^{-1}$ in the three open ocean station samples and from 3.3 to $8.8 \text{ mgCm}^{-3}\text{d}^{-1}$ in the two coastal stations (Table 1, Figure 2). The surface production at the northernmost station J6 was higher by an order of magnitude than those of the other two stations. Most of the stations sampled had higher production in subsurface layers compared to that at the surface (Figure 2). Column production for two

Figure 2. Primary production during the inter-monsoon (I), winter monsoon (II) and summer monsoon (III) periods.

open ocean stations varied from 193 to 199 $\text{mgCm}^{-2} \text{d}^{-1}$ and for the coastal stations from 281 to 306 $\text{mgCm}^{-2} \text{d}^{-1}$ (Table 1). During the winter months the off-shore and inshore surface production varied from 3.8 to 35.8 and 1.1 to 21.4 $\text{mgCm}^{-3} \text{d}^{-1}$. The column production was between 337 and 643 $\text{mgCm}^{-3} \text{d}^{-1}$ in the off-shore region and between 200 and 807 $\text{mgCm}^{-3} \text{d}^{-1}$ in the coastal region. Comparison of production between inter-monsoon and winter monsoon seasons shows higher values during the latter. During the summer monsoon the surface production in the single offshore station was 12.8 while that at the coastal stations varied from 9.4 to 49.9 $\text{mgCm}^{-3} \text{d}^{-1}$. The corresponding column production was 770 at the offshore station while that in coastal stations varied from 440 to 1760 $\text{mgCm}^{-2} \text{d}^{-1}$. Thus during the three seasons sampled, higher production rates were generally observed at the coastal stations with highest being during summer monsoon.

Chlorophyll distribution

The surface chlorophyll concentration was generally

lowest during inter-monsoon seasons, with values in the range of 0.03 to 0.05 mgm^{-3} in both coastal and open ocean stations (Table 1, Figure 3). The column values were also similar ($\sim 11 \text{ mgm}^{-2}$) in these two regions during the season. The chlorophyll distribution exhibited pronounced subsurface maximum (SCM) at 60 m (Figure 3) in all stations sampled. During winter monsoon the surface Chl *a* exhibited a larger range and was between 0.06 and 0.41 and 0.03 to 0.31 mgm^{-3} respectively in the open and coastal water stations respectively. The corresponding column values were between 13 and 27 and 10 and 34 mgm^{-2} . SCM was present only at few stations and was between 40 and 60 m. At two open ocean stations occupied during summer monsoon, surface and column Chl *a* were between 0.41 and 0.45 mgm^{-3} and 34 and 44 mgm^{-2} respectively. Concentrations at the coastal stations varied from 0.09 to 1.34 mgm^{-3} while column values ranged from 16 to 88 mgm^{-2} . At the coastal station J1 where there were evidences of strong upwelling, column Chl *a* and primary production were the highest among all samples measured.

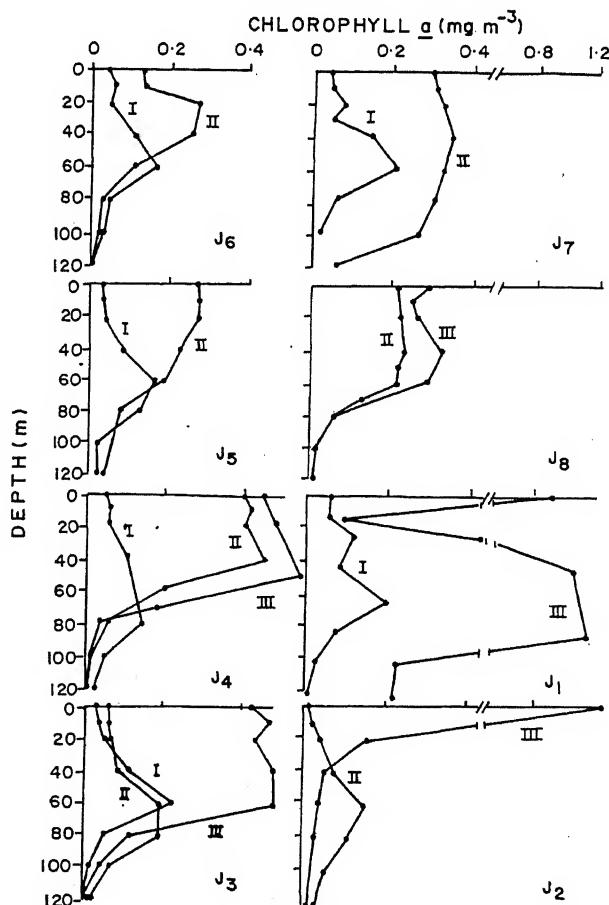

Figure 3. Chlorophyll *a* during the inter-monsoon (I), winter monsoon (II) and summer monsoon (III) periods.

Estimates of the turnover time scales of phytoplankton carbon in the eastern and central Arabian Sea can be derived from the column primary production rate and the standing stock of phytoplankton carbon. The latter was estimated from the measured Chl *a* using appropriate conversion factors (for regimes where nitrate was depleted a factor of 30 was used and where nitrate was repleted and light was limited a factor of 50 was used)⁹. The turnover time scales in the open and coastal stations during the three seasons sampled centered around (1 ± 0.5) days. This would correspond to a division rate of about 0.6–2 per day. These estimates indicate that there is no significant difference in the division rates spatially and temporally in the eastern Arabian Sea.

Particulate organic carbon and nitrogen

Depthwise values of Chl *a*, POC, PON and C/N (atomic ratios) from station J3 are shown in Figure 4 for three seasons. For other stations, measurements were not made for all seasons and therefore not presented here. During inter-monsoon, winter and summer monsoons the POC in the top 120 m had a range from 73 to 150, 140 to 290, 80 to 195 mgm^{-3} , and PON from 7 to 27, 12 to 24 and 5 to 15 mgm^{-3} . C/N ratios were between 7 and 12 up to a depth of 100 m. The ratio was 16 at 120 m.

During winter monsoon C/N ratio was found to be higher with minimum and maximum being 9 and 23. A value of 23 for C/N was found during summer monsoon.

An estimate of the contribution of phytoplankton and zooplankton to the POC could be made by converting the Chl *a* concentration and zooplankton biomass to carbon by appropriate conversion factors. The phytoplankton carbon was estimated by multiplying Chl *a* by a factor of 30 and 50 depending on whether nutrient depleted or repleted and light limited. Zooplankton biomass was converted to carbon¹⁰ by multiplying wet weight by a factor of 0.0235. Contribution by these two was in the range of 5–12 and 5–10%. During monsoon the combined contribution by phytoplankton and zooplankton to POC was 22%.

Productivity in relation to mixed layer settings

During inter-monsoon period, mixed layer along the western shelf was 25 m in the south and 10 m in the north^{11–12}. Along 64°E mixed layer depth (MLD) remained thin with shallowing towards north. During winter monsoon mixed layer varied from 80 m to 120 m, the lower value being at 10°N. Along 64°E MLD deepened from 65 to 125 m between 11 and 17°N and thereafter shoaled to 80 m at 20°N. During summer monsoon MLD in the coastal waters was shallower (15 m) in the

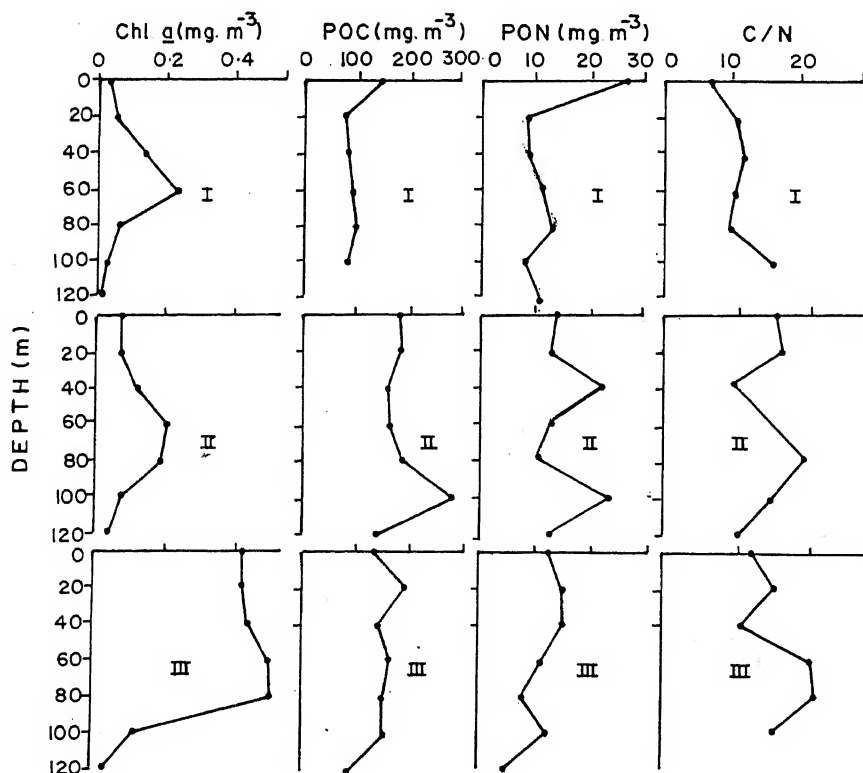

Figure 4. Chlorophyll *a*, particulate organic carbon (POC), particulate organic nitrogen (PON) and C/N ratio (atomic) during inter-monsoon (I), winter monsoon (II) and summer monsoon (III) periods at station J3.

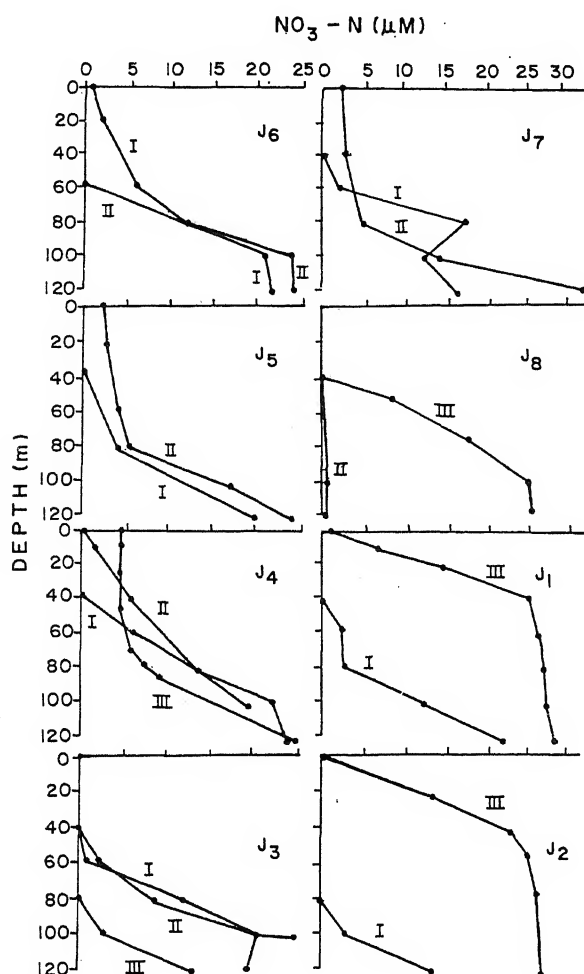

Figure 5. Vertical distribution of nitrate during the inter-monsoon (I), winter monsoon (II) and summer monsoon (III) periods.

south while it deepened northward (45 m). Along 64°E MLD was 90–80 between 11–14°N and about 45 m at 16–18°N.

During inter-monsoon the concentration of nitrate in the shelf and along 64°E was near zero in the upper 40–60 m (Figure 5). 1 μM of nitrate concentration was generally found around 60 m or deeper in most areas. During winter monsoon, the nitrate distribution in the surface waters showed distinct difference between north and south. Shelf waters had near-zero nitrate up to 40 m in the southern region whereas in the northern (off Gujarat) they had 2 μM nitrate at the surface. A similar trend was observed along 64°E. The upper 40 m had near zero nitrate in the southernmost station and further northward 2 μM nitrate was measured at 20 m. During summer monsoon, surface nitrate in the shelf region was high from south of Goa. Thus, off Goa 1 μM nitrate was measured at 24 m, off Mangalore 2.8 μM at 10 m and off Cochin 13.2 μM at 22 m. Along 64°E nitrate was near zero to a depth 100 m in the latitudinal range of

11–18°N except for a patch of 4.6 μM at surface at 16°N.

Discussion

The inter-monsoon period showed lowest primary production and chlorophyll concentration (Table 1, Figure 1). Primary production in the eastern Arabian Sea during April–May was reported to be in the range of 161–1590 (av. 607 $\text{mgCm}^{-2}\text{d}^{-1}$) in the offshore areas and 109–2665 (av. 876 $\text{mgCm}^{-2}\text{d}^{-1}$) in the shelf region¹³. Earlier studies during IIOE have shown that during March–October the shelf waters of Arabian Sea have primary production above 500 and along 64°E between 150 and 500 $\text{mgCm}^{-2}\text{d}^{-1}$. During November–April the same region had more variable production both in the shelf and offshore¹, however the overall values were less with larger areas between 10 and 15°N having low values, i.e. < 100 $\text{mgCm}^{-2}\text{d}^{-1}$. Column primary production has been observed to be more than 1000 $\text{mgCm}^{-2}\text{d}^{-1}$ during southwest monsoon and 500 $\text{mgCm}^{-2}\text{d}^{-1}$ during northeast monsoon over most of the northern Arabian Sea⁷. During August 1987 primary production and chlorophyll *a* between 8 and 20°N was reported to be between 365 and 1130 $\text{mgCm}^{-2}\text{d}^{-1}$ and 13.1 to 32.5 mgm^{-2} in the central Arabian Sea¹⁴. Although the methods adopted for the measurement of primary production earlier were different from those used in the present study, the values during different seasons are generally similar, with the inter-monsoon period having the lowest primary production and phytoplankton abundances. This could be attributed to the low or near-zero nitrate level in the upper layers. During winter monsoon, low surface water temperature caused by cool, dry wind leads to vertical convection and mixing. This enhances the nutrient supply to the mixed layer and results in higher phytoplankton production and chlorophyll *a* has been observed^{15,16}. During this study, the highest primary production was observed during the summer monsoon near the coast. This was due to the upwelling contributing to high nitrate levels in the top layers which in turn supported high phytoplankton production and chlorophyll. Thus at station J1 off Mangalore, where strong upwelling signature was evident, the highest column production and chlorophyll were measured. At this station the nitrate level at 10 m was 2.8 μM , indicating a direct influence of nutrients on the production and chlorophyll. The increase or decrease in both biomass and productivity was in part due to the shoaling or deepening of the mixed layer. For inter-monsoon period, Jochem *et al.*¹⁷ reported primary production in the range of 680 to 790 $\text{mgCm}^{-2}\text{d}^{-1}$ and chlorophyll from 28.7 to 35.8 mgm^{-2} at 18°N, 65°E. During September the primary production and chlorophyll in the coastal Arabian Sea was reported to vary from 235 to 511 $\text{mgCm}^{-2}\text{d}^{-1}$ and from 12 to 46 mgm^{-2}

(euphotic zone was considered as 70 m for computing the column chlorophyll from the mean chlorophyll value given in Table 1)¹⁸.

POC and PON values reported in this work at station J3 (up to a depth of 120 m) had maximum values of 150 and 27 mgm⁻³. Jochem *et al.*¹⁷ observed highest values of both POC and PON from one station from the central Arabian Sea higher than the values reported here. These authors found that subsurface maxima of POC coincided with that of Chl *a*, a result which is not observed in this work. C/N (atomic ratio) measured in this study at J3 was more than that reported by Jochem *et al.*¹⁷. The probable reason for a higher C/N ratio could be due to the higher level of detritus (we have not made any estimate of detritus concentration).

Division rates of phytoplankton as estimated from turnover rate did not show significant seasonal variation with values centering around 2 in the open ocean. Banse⁹ estimated division rates of phytoplankton (from the measurements made during March 1963 and mid-May, 1964) for January–May to be between 0.5 and 1.5 d⁻¹, while for October–November, to be 1.5 d⁻¹. Although there are differences in the type of filters used and techniques adopted for measurements of chlorophyll over the years with corrections applied to earlier data, the estimates of division rates do not seem to differ significantly.

Observations made for the three seasons point towards the seasonal fluctuations in the productivity regimes of the eastern and central Arabian Sea. The entire area becomes more or less oligotrophic during the inter-monsoon period. During winter monsoon the northern latitudes (north of 15°N) became more productive due to winter cooling and convective mixing¹⁵. During the summer monsoon primary production increases along the eastern Arabian Sea as a result of upwelling¹⁸.

Mesozooplankton standing stock, abundance and composition were studied during three seasons (summer, winter and inter-monsoon) from coastal and open ocean waters of the central and eastern Arabian Sea in 1994–95. Concentrations were generally higher in the mixed layer compared to deeper strata. A noteworthy feature was that the standing stocks and abundances did not vary significantly between seasons and areas. Vertical migrations appeared to be in a low key. In all seasons herbivores dominated, followed by carnivores. A few species, common in all seasons, accounted the majority of the population. The 'paradox' of the Arabian Sea, that zooplankton biomass remains more or less invariant, despite seasonally varying primary production regimes, could be explained by a microbial loop.

PRIMARY productivity and phytoplankton biomass show definite seasonal patterns in the Arabian Sea¹. They are high during the southwest (summer) monsoon and part of the northeast (winter) monsoon, and are low during the inter-monsoon periods^{1,2}. They also show north-south and east-west variability² depending on physical events such as upwelling or winter cooling. There are many studies on zooplankton abundances and composition from this region³, however, relatively few of them concentrate on seasonal cycles^{4,5}. Seasonality in zooplankton abundances and composition was addressed as a part of the Indian Joint Global Ocean Flux Study (JGOFS) and sampling was done during three cruises conducted from 12 April to 12 May 1994 (inter-monsoon), 3 February to 4 March 1995 (winter) and 20 July to 12 August 1995 (summer). The stations were positioned to sample the coastal waters along the west coast of India and an open-ocean track along 64° E (Figure 1). A large part of the latter, however, could not be sampled in July–August due to heavy weather.

Materials and methods

The stations (Figure 1) were occupied for at least 24 h to

ensure that sampling of zooplankton was conducted around mid-day and mid-night. Samples were collected with a Multiple Plankton Closing Net (Hydro-Bios, mouth area 0.25 m², mesh width 200 µm). Five depths were sampled at open-ocean stations: 1000–500 m, 500–300 m, 300–base of thermocline (BT), BT-top of thermocline (TT) and TT-surface (mixed layer). At the coastal stations, the two shallow depth intervals were invariably sampled, deeper sampling depended on the bottom depth (Figure 2). Plankton samples were filtered, drained of excess water on absorbent paper and added to

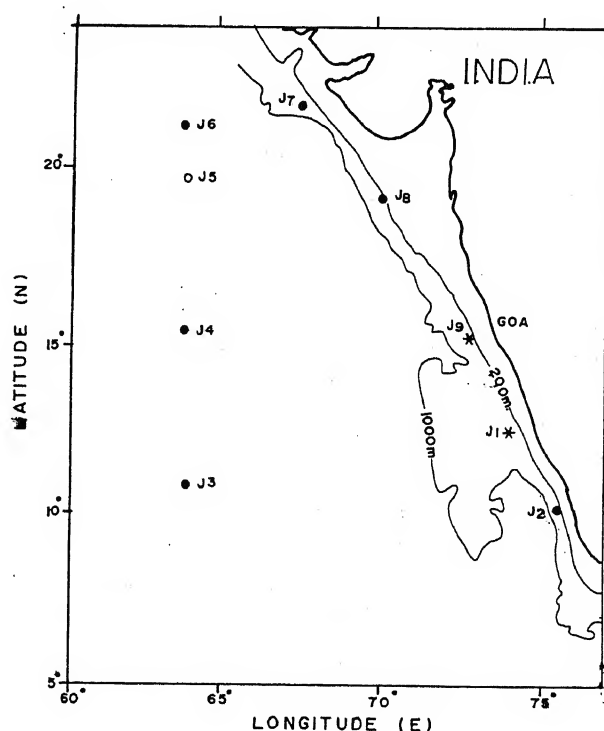

Figure 1. Station locations (filled and open circles and stars) during 3 cruises; open circle (J5)- additional station during February–March, 1995; stars (J1, J9)- additional stations during July–August, 1995; J4 to J7 was not occupied in July–August, 1995; J8 was not occupied during April–May, 1994.

Figure 2. Mesozooplankton biomass (g dry weight 100 m^{-3}) at different depth strata at coastal stations during 3 cruises. Station number is shown. Night-shaded.

known volume of water to estimate biomass. Subsequently, they were preserved in 4% formalin-seawater. A conversion factor of 0.075 g dry weight per 1 ml displacement volume (determined using method described above and without preservation) was used to estimate column and mixed layer standing stocks⁶. Composition of zooplankton from the upper mixed layer, which usually had a higher standing stock, was studied from aliquots. Classification of trophic groups was made according to literature⁶⁻⁹. A Wilcoxon rank test was employed to assess significant spatial (coastal vs open ocean) and day-night variations, if any, in biomass in the mixed layer. This was done separately for each season and then combining data from all cruises. The same test was applied to examine significant day-night variations in total counts and composition of trophic groups of zooplankton in the mixed layer.

Results

Mixed layer was shallow (10–40 m) in April–May and August while it deepened (40–100 m) during February¹⁰. Zooplankton standing stock did not exhibit any definite spatial or temporal trends (Figures 2, 3; Table 1). Aver-

Figure 3. Mesozooplankton biomass (g dry weight 100 m^{-3}) at different depth strata at open ocean stations during 3 cruises. Station number is shown. Night-shaded.

age column standing stocks and the biomass in the mixed layer in coastal and oceanic waters were similar in all three seasons (Table 1, the value for open ocean waters in July–August is based on observation from a single station). The rank test did not show any significant difference ($P > 5\%$) between coastal and oceanic waters within seasons or when all seasons were combined. Biomass decreased drastically with depth, the uppermost two layers sampled accounted for 85 to 95%

Table 1. Average column standing stock of zooplankton (g dry weight m^{-2} , day and night combined, column depths as in Figures 2 and 3) in coastal and open ocean waters during different seasons. Average zooplankton biomass (g dry weight m^{-2}) for mixed layer is given in parentheses

	April-May	February-March	July-August
Coastal	3.7 ± 1.7 (1.4 ± 0.7)	3.1 ± 2.8 (1.6 ± 1.3)	3.3 ± 0.7 (1.3 ± 0.8)
Oceanic	5.7 ± 2.7 (1.5 ± 0.9)	3.1 ± 1.4 (1.7 ± 1.2)	3.3 (1.8)

Table 2. Total number of organisms (per 100 m³, night values) in the mixed layer in coastal and open ocean waters.

	April-May	February-March	July-August
Coastal	51370 ± 22140	4690 ± 29650	61100±50240
Oceanic	91230±59240	81240±32450	23450

in all seasons. Sharp increases in night-time values in the mixed layer were also not clearly discernible ($P > 5\%$) except in some coastal stations indicating that vertical migration was at a low key.

The total number of organisms (night-time values; Table 2) also did not vary much within coastal and oceanic waters in the mixed layer except in August. Neither the

total number of organisms nor trophic groups registered significant night-time increase in the mixed layer. Surprisingly, higher numbers were present in open waters compared to coastal waters during inter-monsoon and winter periods.

Copepods dominated (Table 3), contributing 50 to 88% of the numbers in coastal areas and 77 to 87% in the open ocean. Other dominant groups were Chaetognatha and Tunicata. Herbivores dominated in both areas in all seasons, but appreciable number of carnivores was also present (Table 4). Among copepods, a few herbivorous families, viz. Paracalanidae, Eucalanidae, Calanidae and Clausocalanidae were dominant, accounting for more than 50% of total copepods in all seasons and both areas in the mixed layer (Table 5). These are generally small (< 2 mm, except some species of *Eucalanus*) filter feeding forms. Dominant repre-

*Groups considered as carnivores in Table 3. The trophic status of copepods was classified according to genera, see text.

Table 4. Percentage of abundances of different trophic groups of zooplankton in the mixed layer (day and night combined) in coastal and open ocean waters (latter in parentheses)

Group	April–May	February–March	July–August
Herbivores	57 (57)	53 (54)	66 (69)
Carnivores	33 (35)	43 (41)	25 (21)
Omnivores	10 (8)	4 (5)	9 (10)

representatives from these families were *Acrocalanus* spp., *Paracalanus* spp., *Eucalanus attenuatus*, *E. mucronatus*, *E. subcrassus*, *Cosmocalanus darwini*, *Undinula vulgaris*, *Canthocalanus pauper* and *Clausocalanus* spp. Common carnivorous copepods were the calanoid *Euchaeta (rimana)*, the cycloipoid *Oithona* spp. and the poecilostomatoids *Oncaea* spp. and *Corycaeus* spp.

The composition of copepods was quite similar in the coastal and open ocean waters except that species like *Acartia amboinensis*, *Calocalanus pavo*, *C. plumulosus*, *Temora turbinata*, *Centropages alcocki*, *C. furcatus* and *Labidocera* spp. were more or less restricted to coastal areas. Few others such as *Pleuromamma indica*, *Lucicutia flavicornis* and *Acartia negligens* were ubiquitous albeit occurring in low numbers.

Discussion

The striking feature with regard to zooplankton standing stock and abundances was a general lack of seasonal and spatial variations. Another noteworthy feature was the maintenance of high biomass offshore in the mixed layer comparable to the coastal stations. Zooplankton standing stocks were highest in the mixed layer and sometimes to the base of the thermocline (Figures 2, 3). Sharp decrease in biomass with depth has been described from many areas⁶. Although the oxygen minimum layer (<10 μ M, ca. 150–1000 m) in the Arabian Sea might affect distributions, the present study shows that standing stocks start decreasing at shallower depths. Relatively higher zooplankton counts at coastal stations in summer probably resulted from increase in phytoplankton biomass through coastal upwelling (*vide infra*). Although there was some shift in the percentage of abundance of some copepod families, particularly during summer (Table 5), the overall species composition remained more or less the same. Absence of vertical migration by a large number of dominant epipelagic

copepods has been reported earlier⁶. However, possible zonal migrations⁹ would not be detected with the present sampling strategy.

International Indian Ocean Expedition (IIOE) data¹¹ from the Arabian Sea show much lesser displacement volumes from open waters (ca. 10–40 ml 200 m³ from the upper 200 m) compared to present observations (usually about 20–90 ml 100 m³ from the mixed layer). IIOE also shows some decrease in biomass from summer to winter in the western Arabian Sea although for open waters the variations were less pronounced. One reason for the lower biomass obtained may be the larger mesh size used during IIOE (300 μ m) which might not have effectively sampled the smaller, dominant forms mentioned earlier. A second reason may be that while mixed layer had maximum standing stock, the conversion factor used for IIOE data is for the upper 200 m which also included deeper strata with lower biomass.

A fairly high proportion of carnivores (Table 3) in the zooplankton composition of the Arabian Sea has been reported earlier and this seems to be a persistent situation^{4,6,12,13}. Longhurst and Pauly⁹ noted that the biomass of predators is about twice that of herbivores and detritivores in the tropics compared to colder oceans. It would be of future interest to study how the classical concept of a time-lag between the development of herbivores to carnivores apply to the tropics.

The general lack of seasonality in mesozooplankton standing stocks in the Arabian Sea despite seasonally varying plant biomass has been noticed in some recent studies^{4,14–16}. Seasonal and spatial variations were observed in most of the other biological parameters measured along with the present data set. This Arabian Sea paradox of maintenance of high zooplankton biomass can be plausibly explained through the following scenario. It was observed that in February–March, nutrient availability in the euphotic zone was substantial¹⁷ in the northern coastal and oceanic waters (north of 15°N) due to winter cooling and convective mixing. This led to an increase in primary production, chlorophyll *a* phytoplankton and picoplankton cell counts during this season (up to 800 mg C m⁻² d⁻¹, 34 mg m⁻², 1320 \times 10² l⁻¹ and 45 \times 10⁶ l⁻¹ respectively)^{2,18,19}. A similar feature was observed in August along southwest coast of India (up to 1070 mg C m⁻² d⁻¹, 87 mg m⁻², 155 \times 10² l⁻¹ and 50 \times 10⁶ l⁻¹ respectively); during this period the nutrients were supplied through coastal upwelling. But, during inter-monsoon the entire study area became oligotrophic (values were up to a maximum of 310 mg C m⁻² d⁻¹, 16 mg m⁻² and 93 \times 10² l⁻¹, picoplankton was not counted).

Populations of two groups of organisms, viz. bacteria and microzooplankton, however, showed increased abundances during inter-monsoon compared to the other two periods. Highest bacterial counts were 0.09, 0.6 and 2.2 \times 10⁹ l⁻¹ for the winter, summer and inter-monsoon

respectively¹⁹. These were 56 , 139 and $188 \times 10^3 \text{ m}^{-2}$ for microzooplankton²⁰. It could be envisaged that this happened along with a build-up of dissolved organic carbon pool as the winter bloom became senescent and by the microbial loop.

As mentioned earlier, the herbivorous component of the zooplankton consisted mostly of fine filter feeding copepods and tunicates. It is now established that these organisms are capable of feeding on small organisms such as microzooplankton and even bacteria^{21,22}. It would seem that in the Arabian Sea the herbivorous mesozooplankton are able to sustain the biomass during a lean phytoplankton period through a partial switch over from feeding on phytoplankton to the microbial loop. A high zooplankton biomass would in turn support the bacterial population through its metabolic by-products²³. Such adaptations may not be a dominant feature in high latitude food chains since both phytoplankton and zooplankton increase during/after the

spring bloom. Zooplankton populations are low during winter in these latitudes as most of them produce resting eggs to survive this season²⁴. The high zooplankton biomass in the Arabian Sea also apparently sustains a large biomass of mesopelagic myctophid fishes (100 million tons yr^{-1} in northwestern Arabian Sea)²⁵ which migrate to the surface at night to feed exclusively on zooplankton.

Seasonality and composition of phytoplankton in the Arabian Sea

Surekha Sawant and M. Madhupratap

National Institute of Oceanography, Dona Paula, Goa 403 004, India

Phytoplankton abundance and composition were studied from the central and eastern Arabian Sea during three seasons namely inter-monsoon, winter and summer. Overall, phytoplankton population density was high during winter and summer periods and low during the inter-monsoon. Integrated cell numbers in the upper 120 m was from 0.4 to 1.2, 1.7 to 170 and 0.3 to 10 ($\times 10^8$) cells m^{-2} during inter-monsoon, winter and summer monsoon periods respectively. Diatoms comprised 86% of the total population when three seasons were combined, followed by cyanobacteria (7%) and dinoflagellate (6%). The common diatoms were *Nitzschia* sp., *N. seriata*, *N. longissima*, *Thalassiothrix* spp., *Rhizosolenia* spp. and *Chaetoceros* spp. Some diatoms like *Fragilaria* sp., *Thalassiothrix longissima*, *N. longissima*, *Rhizosolenia* sp. and *Chaetoceros pendulus* were more abundant during the summer monsoon. The genera *Fragilaria*, *Guinardia*, *Hemiaulus*, *Leptocylindrus* and *Lauderia* appeared only during this season. A large number of diatoms were observed in sediment traps during winter.

THE Arabian Sea is an ocean basin where the strength of the physical forcing and biological response vary seasonally. Reversal of surface circulation during monsoon, seasonality in nutrient distribution and high light intensities drive phytoplankton growth processes in the Arabian Sea. Although there is considerable information on the primary production in the Arabian Sea¹⁻⁷, not much is known about phytoplankton abundance and composition except from inshore waters of the west coast of India⁸⁻¹⁰. In this article we compare the phytoplankton communities in the Arabian Sea during inter-monsoon, winter and summer monsoon periods. The research forms part of the Joint Ocean Global Flux Studies. As the main goal of these process studies is to quantify biogeochemical cycling in the Arabian Sea, here we present information on phytoplankton biomass and analyse their seasonal variations from coastal as well as open waters of this region.

Materials and methods

The study was conducted as part of the Joint Global Ocean Flux Studies (JGOFS-India) in the central and eastern Arabian Sea. Collections were made onboard

ORV *Sagar Kanya* in the three cruises conducted from 12 April to 12 May 1994 (inter-monsoon), 3 February to 4 March 1995 (winter monsoon) and 20 July to 12 August 1995 (summer monsoon).

Forty-eight samples were collected from 6 stations during April–May while 56 and 40 samples from 7 and 5 stations, respectively were processed from winter and summer cruises (Figure 1). 250 ml seawater samples were drawn at 0, 10, 20, 40, 60, 80, 100 and 120 m depth from Go-Flo samplers fitted on a CTD rosette. Samples were fixed in 1% Lugol's iodine and preserved in 3% formaldehyde solution. The samples were stored in the dark at low temperature until enumeration within a period of one month after collections.

Figure 1. Station location of ORV *Sagar Kanya* cruises: 12 April–12 May (inter-monsoon), 3 February–4 March (winter monsoon), 20 July–12 August (summer monsoon) '●' denotes the stations occupied, '*' denotes additional stations during July–August, 1995, J4–J7 were not occupied during April–May, 1994, J9 and J11 were not occupied during February–March, 1995.

SPECIAL SECTION: JGOFS (INDIA)

A settling and siphoning procedure was followed to obtain 20–25 ml concentrate. 1 ml of this concentrated sample was examined microscopically in triplicate under a stereoscopic binocular microscope (magnification 100×) in a Sedgewick–Rafter Plankton Counting Chamber for phytoplankton of size >5 µm. Species identification was done according to Subrahmanyam¹¹ and Wimpenny¹². Chain-forming cells were counted on a per cell basis and empty cells were excluded. Phytoplankton not identified to species was collectively placed under generic listings.

Results

Abundances

The integrated phytoplankton cell counts for upper 120 m for different seasons are presented in Table 1. The abundances were generally higher during the winter monsoon, in northern areas both in coastal and open ocean stations compared to inter and summer monsoon periods. The highest cell count (133×10^3 cells l⁻¹) was observed during winter at 15°N 64°E, at 20 m depth (Figure 2 a). Phytoplankton population was dominated by *Nitzschia* sp. (47%) at this depth. Diatoms formed the major group in this season making an overall contribution of 87%, whereas, dinoflagellates contributed 7% followed by cyanobacteria comprising *Trichodesmium* sp. (6%).

The abundance of phytoplankton was quite low during the inter-monsoon period. Integrated cell counts ranged from 0.4 to 1.4 (10^8 cells m⁻²). The offshore stations at 15°N 64°E had the maximum cell count (9.4×10^3 cells l⁻¹) at 20 m (Figure 2 a), where *Nitzschia seriata* and *Chaetoceros* sp. were the dominant phytoplanktons contributing 50% and 15% respectively. Diatoms formed 90% of the phytoplankton during this season followed by cyanobacteria (6%) and dinoflagellates (4%).

The only open ocean station (11°N 64°E) sampled

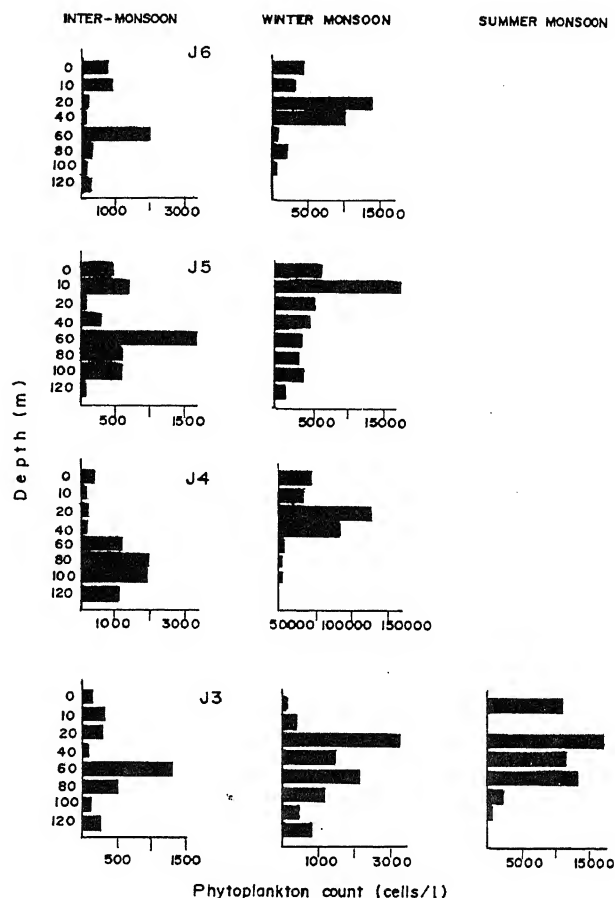

Figure 2 a. Cell concentrations (l⁻¹) at various depths at offshore stations during different seasons.

during summer monsoon had the highest cell count of the season (Table 1). This was also relatively high comparing the three seasons at this southernmost station. The highest cell count (15.5×10^3 cells l⁻¹) was recorded at 20 m depth (Figure 2 a), where diatoms *Thalassiothrix longissima* (29%) and *Chaetoceros pendulus* (26%) formed bulk of the population. Comparable density (13.9×10^3 cells l⁻¹) was recorded at 0 m depth at the coastal station J1 where active upwelling was observed¹³, but numbers rapidly decreased with depth. Unlike at the open waters, the common diatoms recorded were *Rhizosolenia stolterfothii* (18%) and *Guinardia flaccida* (13%). The distribution of phytoplankton at coastal stations during the summer monsoon was restricted to a depth of about 80 m (Figure 2 b). However at coastal station J2, comparatively higher phytoplankton count (2000 cell l⁻¹) was seen at the depth of 100 m (Figure 2 b). The population at this depth was entirely dominated by *Fragilaria oceanica* comprising 96% of the cell count. Overall, diatoms contributed 89% followed by dinoflagellates (6%) and cyanobacteria population decreased to 1% during this season.

Table 1. Integrated phytoplankton abundance (10^8 cells m⁻²; 0–120 m depth) at different stations and seasons

Stations	April–May	February–March	July–August
Open stations			
J3 11°N 64°E	0.5	1.7	10
J4 15°N 64°E	1.2	47.0	—
J5 19°N 64°E	0.8	6.1	—
J6 21°N 64°E	0.7	55.4	—

J7 21°N 67°E	0.4	170.0	—
J8 19°N 70°E	—	91.0	0.4
J9 15°N 70°E	—	—	0.3
J1 12°N 74°E	—	—	2.3
J2 10°N 75°E	1.4	3.4	0.7

— indicates no observation was made.

Figure 2b. Cell concentrations (l^{-1}) at various depths at coastal stations during different seasons.

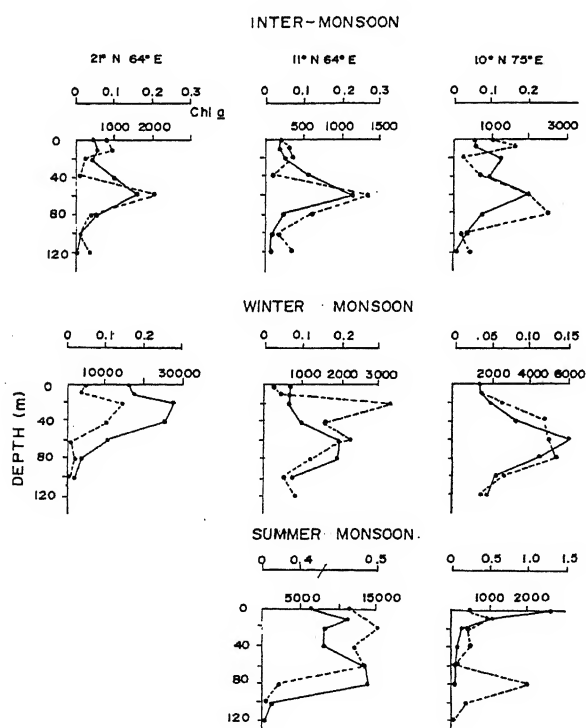

Figure 3. Phytoplankton distribution ($cells\ l^{-1}$, solid lines) and chlorophyll *a* ($mg\ m^{-3}$, broken lines) at 3 stations during the inter-monsoon and winter monsoon seasons and 2 stations during the summer monsoon.

Higher phytoplankton population was observed at subsurface depths (10–80 m) at the different stations during the three seasons (Figure 2a, b). Generally, the peak in phytoplankton abundance showed a direct relation to the subsurface chlorophyll maximum (SCM)

layer which varied from 20 to 60 m (Figure 3).

Assemblages

A variety of phytoplankton taxa (36) were identified. The more abundant genera and species are listed in Table 2. Diatoms were the dominant group followed by dinoflagellates and cyanobacteria. During inter-monsoon, population was dominated by species like *Nitzschia seriata*, *N. closterium* and *N. pungens* at all the stations (ca. 25% of total population), except at $15^{\circ}N\ 64^{\circ}E$, where *Navicula* was common (22%) followed by *Rhizosolenia* spp. (10%) and *Chaetoceros* sp. (9%). Dinoflagellates were represented by *Ceratium* sp. and *Peridinium* sp. constituting 4%.

During winter monsoon, the dominant phytoplankton taxa were *Nitzschia* sp. (37%), *N. seriata* (21%), *Chaetoceros* sp. (8%), *Rhizosolenia* spp. (7%) and *N. longissima* (5%). Dinoflagellates were represented by *Ceratium* spp., *Peridinium* sp., *Dinophysis* sp., *Prorocentrum* sp. and *Gymnodium lunula*. *Rhizosolenia* spp. however, were generally dominant at coastal stations, constituting 20%. Some diatoms like *Bellarochea* sp., *Schroderella* sp., *Cyclotella* sp., *Streptotheca* sp., *Climacodium* sp., and *Hyalodiscus* occurred in few numbers.

Maximum variety of diatom species occurred during summer monsoon. Important species in terms of abundance were *Thalassiothrix longissima* (22%), *Nitzschia longissima* (8%), *Chaetoceros* sp. (5%), *Rhizosolenia* sp. (5%), *R. stolterfothii* (4%), *N. seriata* (4%) and *Thalassiosira* sp. (2%). Species of diatoms belonging to the genera *Ditylum*, *Eucampia*, *Fragilaria*, *Guinardia*, *Gyrosigma*, *Hemiaulus*, *Hyalodiscus*, *Leptocylindrus*, *Lauderia*, *Lymnophora* and *G. flaccida* occurred only during summer monsoon, and at the coastal stations in particular.

The other species which were recorded in low densities in the present study and not listed under Table 2 or elsewhere, were *Actinopterychus* sp., *Asteromphalus* sp., *Biddulphia aurita*, *B. mobiliensis*, *Ceratualina* sp., *Climacosphaenia* sp., *Chaetoceros affinis*, *C. contortum*, *C. schuttii*, *C. holsaticus*, *C. teres*, *C. decipiens*, *C. curvisetus*, *C. constrictus*, *C. didymis*, *Melosira* sp., *Nitzschia bilobata*, *N. directa*, *Pleurosigma* sp., *Planktoniella* sp., *Rhizosolenia delicatula*, *R. hebatata*, *Stephanopyxis* sp., *Thalassiosira* sp., *Thalassiothrix nitzschoides*, *T. frauenfeldii*, *Tropedoneis* sp., *Ceratium furca*, *C. fusus*, and *C. bucephalum*.

Discussion

In this paper we present the floristic documentation of the seasonal composition and abundance of the

SPECIAL SECTION: JGOFS (INDIA)

phytoplankton of the eastern and central Arabian Sea.

Species encountered in this study have been reported in the checklist for diatoms of the Indian Ocean¹⁴, and previously recorded from the west coast of India^{8,9}.

The population was dominated by diatoms at both coastal and open waters in all seasons. The abundance of this group (all seasons combined) was 86%. Subrahmanyam and Sarma¹⁰ reported the dominance of diatoms during summer monsoon but list Dinophyceae as more abundant during post-monsoon (September–October) period. However, dominance of diatoms during both post and premonsoon has also been noted in earlier

studies from the coastal waters of west coast of India¹⁵. The most common diatoms encountered in the present study were *Nitzschia* spp., *Navicula* sp., *Chaetoceros* spp. and *Rhizosolenia* spp.

Among the seasons sampled, the winter and summer monsoon were more conducive for phytoplankton population. About 25% of the total photosynthetic production of the Arabian Sea occurs in the northern regions in winter¹ as corroborated in our cell counts (Table 1). During winter monsoon, deepening of the surface layer and vertical mixing due to convection¹³ enhanced nutrient availability, leading to increase in phytoplankton

Table 2. Mean seasonal concentrations (cells l⁻¹) of common phytoplankton species at coastal and open ocean stations (I = intermonsoon, W = winter monsoon and S = summer monsoon)

population (Table 1, Figure 2 a, b). The northern coastal and offshore areas above 15°N latitude, were found to be more productive during winter¹⁶. Kuz'menko¹⁷ also reported high abundance of phytoplankton in terms of numbers as well as biomass during this season from the central region of the Arabian Sea.

Along the south west coast of India, upwelling which bring nutrients to the euphotic zone, starts with the onset of the summer monsoon in May–June, and intensifies in July–August^{18–21}. This leads to marked increase in phytoplankton growth (e.g. at 12°N 74°E) where active upwelling was observed²². The corresponding column Chl *a* and column primary production values at this station were also high (80 mg m⁻² and 1.7 gCm⁻²d⁻¹ respectively)²². This is also reflected in the surface cell counts we obtained. The only offshore station, at 11°N 64°E, which was sampled during this season also showed higher cell count (Table 1) and high column Chl *a* (44 mgm⁻²) and primary production (770 mgCm⁻²d⁻¹), despite the absence of upwelling signature^{22, 23}. An interesting feature observed during the summer monsoon was the decrease in cyanobacteria population from 6% to 1%. This is probably because *Trichodesmium* requires stable, warm conditions for their growth²⁴. The occurrence of *Fragilaria oceanica* has been noted to be common during the summer monsoon in the coastal waters of the west coast of India²⁴. The phytoplankton production and cell counts during the inter-monsoon remained low. The nutrient supply and chlorophyll values also showed declination during this season^{16, 25}.

We observed that maximum concentrations of phytoplankton usually occurred at intermediate depths (10–80 m). Thus the phytoplankton abundances showed a direct relation with the subsurface chlorophyll maximum layer, at the nutricline²⁴, especially, during the inter-monsoon period (Figure 3). The restriction of their distribution at coastal stations during summer monsoon to a depth of ca. 80 m seems to result from high turbidity.

A large number of diatoms were seen in floating sediment trap samples (deployed during winter) at 300 m depth at 15°N 64°E station (Dr V. Ramaswamy, pers. comm.). The diatoms *Rhizosolenia* sp., *Nitzschia* sp., *Thalassiosira* sp., *Navicula* sp., *Coscinodiscus* sp. common in the water column were found in significant numbers (ca. 3×10^3 cells l⁻¹). Presence of intact diatoms in traps at shallow depth (80 m) has been reported from the western Arabian Sea during inter-monsoon season²⁶. The floral composition also was somewhat similar. The dominant forms were *Rhizosolenia*, *Chaetoceros* and *Guinardia* spp. Although phytoplankton may be consumed or mineralized in the surface waters (or form aggregates and sink out), their presence as recognizable forms at this aphotic depth (300 m) points to role of

phytoplankton in rapid carbon export. This may also indicate that during productive periods (summer and winter), mesozooplankton grazing does not effectively control the phytoplankton production in the Arabian Sea²⁷.

Studies on the microzooplankton from the central and eastern Arabian Sea

Mangesh Gauns, R. Mohanraju and M. Madhupratap

National Institute of Oceanography, Dona Paula, Goa 403 004, India

Numerical abundance and composition of microzooplankton in the upper 200 m were studied from the central and eastern Arabian Sea during three seasons. Protozoans, comprising of ciliates (loricates and aloricates), flagellates and sarcodines were dominant, ranging from 55% to 91%. Among metazoans, nauplii and copepodite stages were common. Microzooplankton abundance was generally higher in the upper 100 m water column during all the three seasons. The column values were from 69,000 m⁻² to 188,000 m⁻² (inter-monsoon), 7350 m⁻² to 56,350 m⁻² (winter monsoon) and 10,800 m⁻² to 139,150 m⁻² (summer monsoon). Seasonal averages were 700 l⁻¹, 130 l⁻¹ and 310 l⁻¹ respectively. A maximum of 5000 l⁻¹ was observed during summer at 5 m at a coastal station. Microzooplankton carbon in three different seasons ranged from a minimum of 4 µg C l⁻¹ during summer monsoon to a maximum of 36 µg C l⁻¹ during inter-monsoon and was higher than that of mesozooplankton. Peaks in population observed during inter-monsoon season, when phytoplankton productivity was low and relatively high bacterial abundance was observed, indicated a microbial loop.

As a part of the Joint Global Ocean Flux Studies (JGOFS-India), abundance and composition of microzooplankton were studied from the central and eastern Arabian Sea. They form a key component in cycling of carbon and other nutrients in marine surface waters^{1,2}. There is virtually no study on microzooplankton from this area. Microzooplankton are defined as the phagotrophic animal forms which pass through a 200 µm mesh netting³. They are taxonomically heterogeneous comprising both protozoa and metazoa. It is known that the microplankton form a significant proportion of the plankton community in the epipelagic zone, in oceanic, coastal and estuarine waters⁴⁻¹³. In India, studies on the microzooplankton are limited to the work on tintinnids from the Vellar estuary, Pichavaram mangroves and the adjacent coastal areas along the east coast¹⁴⁻²⁰. We report here, for the first time, a study on the annual cycle of the microzooplankton abundance and composition from the Arabian Sea.

Materials and methods

Samples for microzooplankton were collected following the JGOFS protocol²¹. Water samples were ob-

tained from a CTD rosette sampler fitted with Go-Flo bottles (12 litre capacity, General Oceanics). The Go-Flo bottles were triggered during upcast at depths of 200, 150, 100, 50 and 5 m.

The collections were made during three seasons: inter-monsoon (April–May 1994), winter monsoon (February–March 1995) and summer monsoon (July–August 1995) onboard O. R. V. *Sagar Kanya* cruises (Figure 1). Samples were processed in the following manner: To quantify the larger (20–200 µm) microzooplankton, 10 litres of water from the Go-Flo bottle was filtered through 200 µm net into a bucket. This water was then slowly passed through a wide area of 20 µm net. The filtration was done carefully and slowly to avoid bursting of delicate forms due to pressure exerted while filtering. The filtered micro-zooplankton was then transferred to 500 ml GF/F filtered sea water and preserved with 1% Acid Lugol's solution, 1% EM hexam-

Figure 1. Station locations during three cruises. ●, stations sampled, *, additional station sampled during July–August 1995. Stations J2–J7, J1–J8 and J1–J4, J8, J9 were sampled during April–May, February–March and July–August respectively.

ine buffered formaldehyde and 2 mg/l of strontium sulphate. Samples were refrigerated in dark until analysed later in the laboratory. These samples were used for enumeration, identification and to measure the biomass.

In the laboratory these samples were left undisturbed and allowed to settle for more than 48 h. These were then concentrated to 50 ml by siphoning out the supernatant and observed under an inverted microscope with phase contrast optics⁷. Microzooplankton were identified to genus level based on literature²²⁻²⁶. They were assigned to the following five groups: metazoa, tintinnids, sarcodines, flagellates and aloricates. Metazoa were not counted during intermonsoon and cells were grouped as loricates and other protozoans. Cell dimension (μm) of protozoans was determined from microscopic measurements in order to compute the volumes. This was converted to carbon using a factor of $0.19 \text{ pg C } \mu\text{m}^{-3}$ for ciliates²⁷ and $0.14 \text{ pg C } \mu\text{m}^{-3}$ for dinoflagellates²⁸. A conversion factor of $16 \text{ ng C/individual}$ was used for metazoan microzooplankton²⁹. While computing the biovolume of protozoans 40% cell shrinkage due to preservation³⁰ was taken into consideration. The cell volume of tintinnine ciliates in the present study was assumed to be 50% of lorica volume. Mesozooplankton biomass (0–200 m depth) estimated as displacement volume³¹ was converted to dry weight (1 ml displacement volume = 0.075 g dry wt.) and to carbon (34.2%)³².

For studying the abundance of heterotrophic flagellates, 50 ml of fresh sea water samples from depths mentioned earlier was fixed in 2% glutaraldehyde (only during the winter and summer monsoon). These were then stained with DAPI (final concentration of $5 \mu\text{g/ml}$)^{33,34} and counter-stained with Proflavin and after 5 minutes concentrated onto $0.8 \mu\text{m}$ black Nuclepore filters of 25 mm diameter^{34,35}. These were stored at 5°C until observed under an epifluorescent microscope (Olympus) under UV excitation with a blue filter. Only unbroken well-defined organisms were counted.

Results

Composition

Protozoans were dominant at all stations during the three seasons. They mostly comprised of ciliates (both loricates and aloricates), sarcodines and flagellates. Tintinnids were represented by 30 genera. Among these 11 genera, *Tintinnopsis*, *Eutintinnus*, *Favella*, *Parundella*, *Amphorides*, *Codonellopsis*, *Rhabdonellopsis*, *Dictyocysta*, *Codonella*, *Tintinnus* and *Xystonellopsis* were present during all the three seasons. Other genera recorded were *Metacylis*, *Ascampbelliella*, *Parafavella*, *Coxiella*, *Dadayiella*, *Ormosella*, *Proplectella*, *Protorhabdonella*, *Rhabdonella*, *Epiplocyclis*, *Salpingella*, *Luminella*, *Stenosemella*, *Tintinnidium*, *Helicostomella*,

Leprotintinnus, *Daturella*, *Undella* and *Climacocylis*. Sarcodines were represented by radiolarians, acantharians and foraminiferans. Apart from these, flagellates consisted of *Peridinium*, *Ceratium*, *Dinophysis*, *Goniaulax*, *Noctiluca*, Silicoflagellates and *Prorocentrum*. Metazoa were mostly copepod nauplii, early copepodite stages, larval stages of appendicularians, polychaetes, chaetognaths and eggs of copepods and fishes.

Seasonal abundance of microzooplankton

Microzooplankton abundance during the three seasons in the central and eastern Arabian Sea is shown in Figures 2a,b. Average cell concentration of microzooplankton was highest during inter-monsoon (700 l^{-1}) followed by summer (300 l^{-1}) and winter (130 l^{-1}) seasons and average integrated column values were $143,000 \text{ m}^{-2}$, $66,000 \text{ m}^{-2}$ and $24,100 \text{ m}^{-2}$ respectively. Protozoa contributed 55–91% to the total microzooplankton. Among protozoa, flagellates (avg. 47%) were abundant followed by loricates (27%), aloricates (21%) and sarcodines (5%). Copepod nauplii and early copepodite stages of copepods formed the major component of the metazoan microzooplankton. Higher abundance of microzooplankton was found in the upper 100 m compared to 100–200 m depth except at stations J5 and J6 during inter-monsoon period. Below 100 m flagellates and aloricate ciliates were usually more common compared to other taxa. Microzooplankton density was higher in open ocean waters during inter-monsoon and winter while it was more at coastal stations during summer. During inter-monsoon there was not much variation in abundance between northern (avg. 700 l^{-1}) and southern (avg. 716 l^{-1}) stations, but during winter and summer seasons southern areas showed more abundance (351 l^{-1} and 180 l^{-1} respectively) than north (78 l^{-1} ; 140 l^{-1}).

Microzooplankton carbon ranged from 7 to $36 \mu\text{g C l}^{-1}$ (avg. $19 \mu\text{g C l}^{-1}$), 4 to $22 \mu\text{g C l}^{-1}$ (avg. $10 \mu\text{g C l}^{-1}$) and 4 to $25 \mu\text{g C l}^{-1}$ (avg. $12 \mu\text{g C l}^{-1}$) during inter-monsoon, winter and summer respectively. Southern stations showed comparatively higher biomass (avg. 3.96 g C m^{-2}) than the northern stations (1.96 g C m^{-2}). Microzooplankton biomass in terms of carbon was more than that of mesozooplankton in all seasons except in open ocean waters during winter monsoon when they were comparable (Table 1).

Discussion

Numerically, microzooplankton was dominated by protozoa which contributed on an average >75%. This is comparable to the results reported from Plymouth waters¹¹ where protozoa contributed to >97% of counts in

Figure 2a. Microzooplankton abundance during inter-monsoon, winter monsoon and summer monsoon at coastal stations (J1, J2, J7, J8 and J9).

the water column. Ciliates and flagellates dominated in the present study as reported¹¹.

An interesting finding of this study was the contribution of flagellates which ranged from 11 to 69% to the total microzooplankton. This suggests that they form an important group of microzooplankton in tropical waters similar to subtropical and temperate waters^{1,36-38}. Tintinnid population varied from 20 to 1060 l^{-1} in the present study, is less than that reported during the north Atlantic bloom (300–1600 l^{-1})² but higher than

Table 1. Average carbon content ($g C m^{-2}$) of microzooplankton and mesozooplankton

	Inter- monsoon	winter monsoon	Summer monsoon
Microzooplankton			
Open ocean stations	3.1	1.8	2.3
Coastal stations	5.48	2.1	2.4
Mesozooplankton			
Open ocean stations	1.51	1.89	0.87
Coastal stations	0.92	0.90	1.00

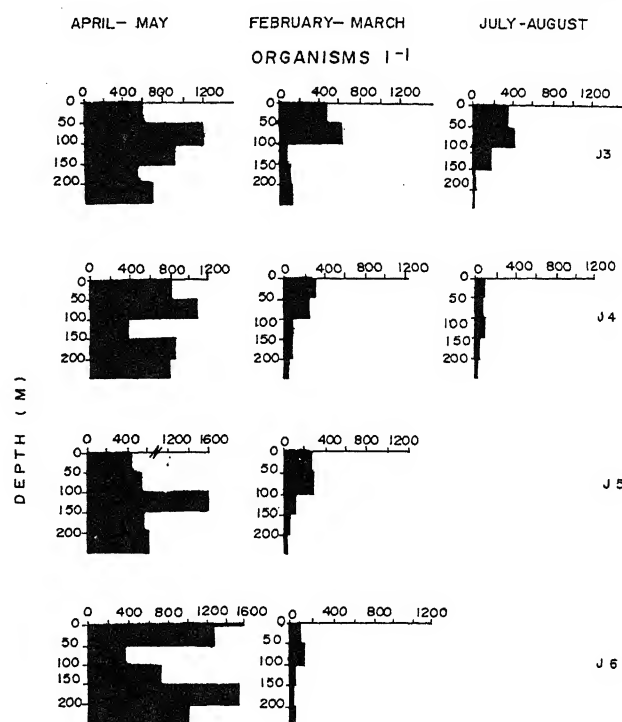

Figure 2b. Microzooplankton abundance during inter-monsoon, winter monsoon and summer monsoon at open ocean stations (J3-J6).

records from the Pichavaram Mangrove (4–13 l^{-1})²⁰, South India. Similarly, microzooplankton biomass of this study (4–36 $\mu g C l^{-1}$) is comparable to that of Lancaster Sound 10, where microzooplankton (>35 and <200 μm) biomass varied from 1.33 $\mu g C l^{-1}$ to 48.7 $\mu g C l^{-1}$. The assumption of taking cell volume of tintinnids as 50% of lorica volume might have led to some over-estimation³⁹.

The physical and chemical environments during the three cruises were different. During February, winter cooling led to increased mixed layer depths and availability of nutrients in euphotic zone enhancing primary production in the northern region⁴⁰. During April-May, the entire study area was oligotrophic whereas in August enhanced production was noticed in coastal waters as a result of upwelling. Interestingly, maximum population of microzooplankton occurred during inter-monsoon season when primary production and chlorophyll were low, but bacterial population was high compared to other seasons⁴¹. It would seem that the microzooplankton population increased through a microbial loop during this season by actively feeding on bacteria⁴². Higher microzooplankton abundance below 100 m at some stations during inter-monsoon coincided with trends in distribution of bacteria. The higher population of microzooplankton in coastal waters during summer monsoon might have resulted from the fresh water plumes⁴³ due to river run-off.

The fact that microzooplankton biomass in terms of carbon usually exceeded that of mesozooplankton is a pointer that they dominate the food chain in grazing and thereby phytoplankton losses as reported from the Atlantic^{1,2}. Future studies should concentrate on this since this implies that it forms the largest sink for primary production.

Bacterial abundance and production in the central and eastern Arabian Sea

N. Ramaiah, S. Raghukumar and Mangesh Gauns

Biological Oceanography Division, National Institute of Oceanography, Dona Paula, Goa 403 004, India

Seasonal and spatial variations in bacterial and picoplankton abundances and bacterial production (thymidine incorporation rates) were determined in the water column up to 150 m in several stations in the central and eastern Arabian Sea. Higher bacterial densities of about 1×10^9 cells L^{-1} were observed during the intermonsoon periods of September and April/May compared to the southwest monsoon period of July/August and the winter period of February/March. Although primary production was low during April/May, bacterial production was much higher during this period unlike July/August. It also showed an increase from the northern to the southern Arabian Sea, suggesting the presence of high amounts of dissolved organic carbon in this area. High picoplankton densities, ranging up to 45×10^6 cells L^{-1} were observed during February, particularly in the northern Arabian Sea. Rapid turnover of bacteria during the intermonsoon period of April/May suggests the predominance of a 'microbial loop' in the foodweb and a prevailing source of dissolved organic carbon in the oceanic waters.

THE Arabian Sea is characterized by several unique seasonal and spatial variations in terms of biological, physical and chemical features which would directly influence microbial processes. Enormous amounts of particulate and dissolved organic carbon (POC and DOC) become available to bacteria during the southwest (summer) and northeast (winter) monsoons owing to enhanced primary production^{1,2}. Wind-driven upwelling during the southwest monsoon from June to September results in extensive areas of high primary production along the northwestern regions and the south and central west coast of India^{1,3-5}.

In addition, distinct differences between the northern and southern Arabian Sea will be reflected in the bacterial dynamics. High primary production is sustained in the northern Arabian Sea even after the southwest monsoon owing to cold and dry winds which result in convective mixing^{1,3,6}. While primary production decreases towards the south², DOC tends to increase from the north to the south. The subsurface waters of the northern Arabian Sea display a pronounced oxygen minimum layer associated with high nitrite maxima. The high-nitrite ridge extends from the continental margin off the north into the relatively oligotrophic central Arabian Sea. Primary production, *per se*, thus appears

to be decoupled from microbial processes that lead to denitrification⁷.

The months of March to May are periods of low primary production in the Arabian Sea³ and the possible effects of alternating eutrophy and oligotrophy on bacterial dynamics in the Arabian Sea, suggested by Azam *et al.*⁸ would be particularly felt during this season.

A few attempts have been made in recent years to study bacterial activities and picoplankton in the Arabian Sea⁹⁻¹². However, these studies have largely been confined to the monsoon period of July to October and the upwelling areas in the northwest Arabian Sea. Bacterial dynamics during the other seasons and parts of the Arabian Sea still remain poorly investigated.

The present study, as a part of the Joint Global Ocean Flux Studies-India (JGOFS) attempts to address: (1) Bacterial populations and production during the monsoon and intermonsoon periods, (2) Differences between the northern and southern Arabian Sea, and (3) Picoplankton abundance.

Materials and methods

Bacterial abundance

Four cruises were undertaken on board ORV *Sagar Kanya*: (1) Cruise SK #87 during September 1993; (2) SK #91 during April-May 1994 (3) SK #99 during February-March 1995, (4) SK #104 during 4 July-August 1995. Water samples were collected at various depths from different locations (Figure 1) using a CTD rosette sampler. Samples for microbiological studies were drawn from the rosette immediately after samples for dissolved gases were taken. These samples were handled, stored and analysed for bacterial abundances essentially according to the JGOFS protocols¹³ except for the addition of 0.22 μm filtered formaldehyde (3.7% final concentration) instead of 10% glutaraldehyde. Acridine orange direct counts (AODC) for bacteria were carried out following Parsons *et al.*¹⁴ and the JGOFS protocols. Up to 25 microscopic fields were counted for bacteria using oil immersion objectives (100 \times) under an Olympus BH2 epifluorescence microscope. Mean cell numbers per field were calculated and the number

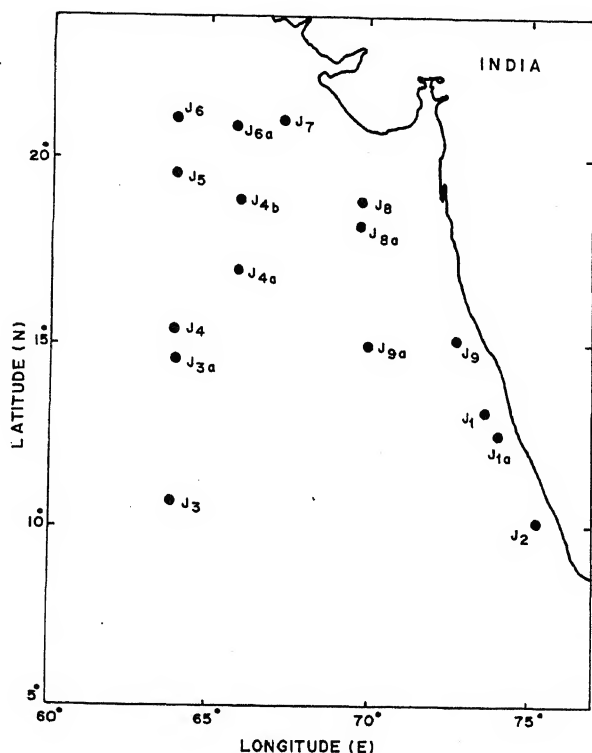

Figure 1. Location of sampling stations.

of bacterial cells L^{-1} determined based on the relationship detailed in Parsons *et al.*¹⁴.

3H (tritiated) thymidine incorporation rates

Incorporation of 3H -methyl (tritiated) thymidine (specific activity: 17,000 mCi/mmol; Bhabha Atomic Research Centre, Mumbai) by native bacteria was estimated by the method described in JGOFS protocol¹³ during cruises #SK 91 and #SK 104. Seawater samples from various depths, up to 150 m, were collected and analysed. A working solution of 21.25 ml containing 59 nmole of methyl 3H thymidine was prepared and 100 μ l of this solution was added to 27.8 ml of water sample to yield a final concentration of 10 nM thymidine. Samples were incubated for 1 h and the uptake was stopped by adding 37% formaldehyde to yield a final concentration of 3%. The aliquots were immediately filtered over 0.2 μ m Millipore filters and cold TCA precipitation and ethanol extraction carried out. Filters were immersed in 3 ml of liquid scintillation cocktail ('Cocktail-W', Spectrochem, Mumbai) and the samples assayed for radioactivity using a Packard 2500 TR liquid scintillation counter.

Bacterial production was estimated using mean oceanic conversion factor values of 2.17×10^{18} cells mol^{-1} thymidine incorporated and by converting the cell abun-

dance to carbon mass using a value of 2×10^{-14} g C per cell¹⁵.

Results

The observations presented in this paper pertain to four different seasons. The summer monsoon period in July/August 1995 was characterized by higher primary production and phytoplankton biomass, especially along the west coast of India (see Bhattathiri *et al.*, this issue). Decay of phytoplankton blooms occurred during September 1993 (SK #87). Primary production and phytoplankton biomass were also quite high in the northern latitudes during the winter month of February 1995 (SK #99). The intermonsoon period in April/May 1994 had the lowest levels of primary production and phytoplankton biomass of all the seasons sampled.

The highest bacterial densities, ranging from 0.34 to 1.5×10^9 cells L^{-1} were observed at the end of the southwest monsoon (September 1993) at the three stations sampled in the northern Arabian sea along $66^\circ E$ (Figure 2). Subsurface maxima were evident in all these locations. High bacterial densities were also observed

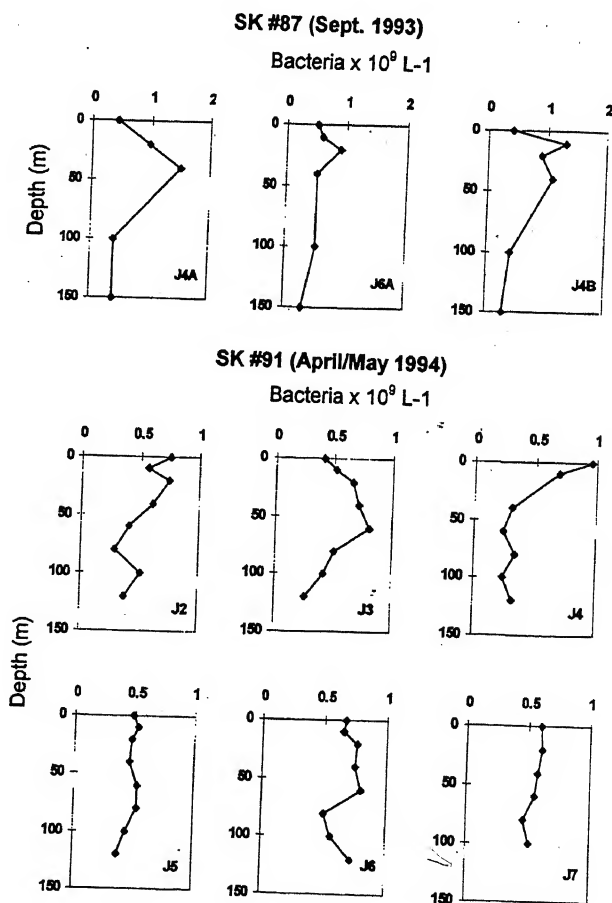

Figure 2. Bacterial abundance during cruises SK #87 (September 1993) and SK #91 (April/May 1994).

in the intermonsoon period of April–May 1994 (Figure 2; range: $0.24\text{--}0.96 \times 10^9 \text{ L}^{-1}$). However, no sharp sub-surface maxima were detected at any of the locations during this period. The coastal stations (for example, J2 and J7) and the offshore stations in the central Arabian Sea (J3 and J4) had similar bacterial abundances. Bacterial numbers were more or less similar from north to south along 64°E (Figure 2). Bacterial densities during the summer monsoon (SK #104) were fairly high, ranging from 0.13 to $0.64 \times 10^9 \text{ L}^{-1}$ (Figure 3). As in the intermonsoon season, bacterial abundances in coastal stations (J2, J8A and J9) and in the open oceanic stations (J3 and J3A) were similar. These numbers, however, were slightly lower than those observed in September and April. In contrast, bacterial abundance was about an order of magnitude lower (0.05 to $0.09 \times 10^9 \text{ L}^{-1}$) during February 1995 in all sampling stations, except the northernmost, coastal station J8 (Figure 4).

Thymidine incorporation rates were measured during the intermonsoon (SK #91) and the summer monsoon (SK #104) cruises (Figures 5 and 6). During the former, higher uptake rates, up to 25 to $50 \text{ pmol L}^{-1} \text{ h}^{-1}$, were observed in the southern coastal station J1 and the southern offshore stations, J3 and J4, all below the latitude of 15°N . Many of the stations showed higher rates at about $40\text{--}60 \text{ m}$ depths. Uptake rates during summer monsoon ranged from 0.2 to $3 \text{ pmol L}^{-1} \text{ h}^{-1}$, about an order of magnitude lower than those observed in the intermonsoon (Figure 6). The highest uptake rate during this season occurred in the southern coastal station J1A. Bacterial production increased with depth in all the stations except J1A.

Bacterial production (BP) exceeded primary production (PP) throughout the 120 m water column in 3 out of the 4 stations during intermonsoon (Figure 7). PP in the

Figure 4. Bacterial abundance during cruise SK #99 in February/March 1995.

upper 50 m at some of these stations was only about 2% of the BP. In contrast, PP during the summer monsoon far exceeded the BP till a depth of 40 m (Figure 7), BP contributing only ca. 10% of the PP.

High picoplankton abundance, with a maximum of up to $60 \times 10^6 \text{ cells L}^{-1}$ was observed in the northern stations during February/March 1995, compared to ca. $10 \times 10^6 \text{ cells L}^{-1}$ in the more southern, oceanic stations (Figure 8). Picoplankton densities were similar to these oceanic waters during summer monsoon. However, the southernmost coastal station J2 harboured high numbers of picoplankton similar to coastal stations during February/March 1995 (Figure 8).

Figure 6. Thymidine incorporation rates during cruise SK #104 in July/August 1995.

Discussion

Peak bacterial abundances were not related to seasons of high primary productivity during the summer or winter monsoons. Thus, the highest bacterial densities were observed at the end of the southwest monsoon in September (Figure 2). Although only three stations at the northern Arabian Sea were sampled during this period,

the high bacterial densities observed during this period are probably typical of this season. The values measured in this study are similar to those reported by Ducklow⁹ ($>1 \times 10^9 \text{ L}^{-1}$) for the Northern Arabian Sea and the Gulf of Oman during September 1994. Likewise, although a pronounced enhancement of primary production and phytoplankton biomass and high picoplankton abundance with a distinct north to south gradient occurred along 64°E as a result of winter cooling and convective mixing⁵ (Figure 8), bacterial densities were not related to such high primary production and were the lowest during this season for the Arabian Sea.

Bacterial abundance increased substantially by April/May at all stations sampled (Figure 2). This period is generally known to be a season of low primary productivity and oligotrophic conditions in the Arabian Sea^{3,16}. Increase in bacterial abundance during the two intermonsoon periods in September and April/May might be related to a decay of the earlier phytoplankton blooms, increasing phytoplankton exudation and particle breakdown at the end of the season⁹. Our observations during April/May suggest that bacteria during this season responded to the phytoplankton blooms of February/March only after a pronounced lag period¹⁵. In the equatorial Pacific, Kirchman *et al.*¹⁷ observed a lack of covariance and an uncoupling between primary and bacterial productions over a similar time scale of about 1–2 months. Azam *et al.*⁸ suggested that following a phytoplankton bloom, labile DOC would be rapidly utilized by bacteria, while the slow-to-degrade DOC would

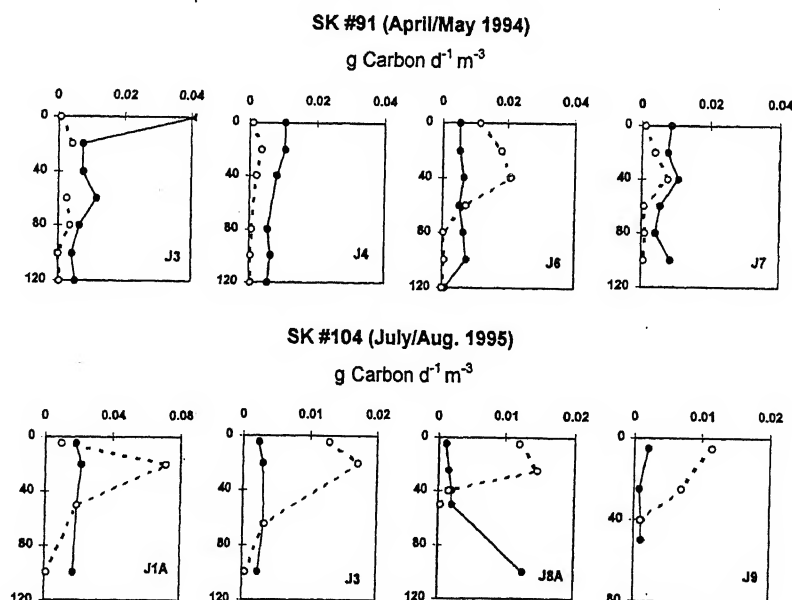

Figure 7. Bacterial (continuous lines) and primary (stippled lines) production during cruises SK #91 in April/May 1994 and SK #104 in July/August 1995.

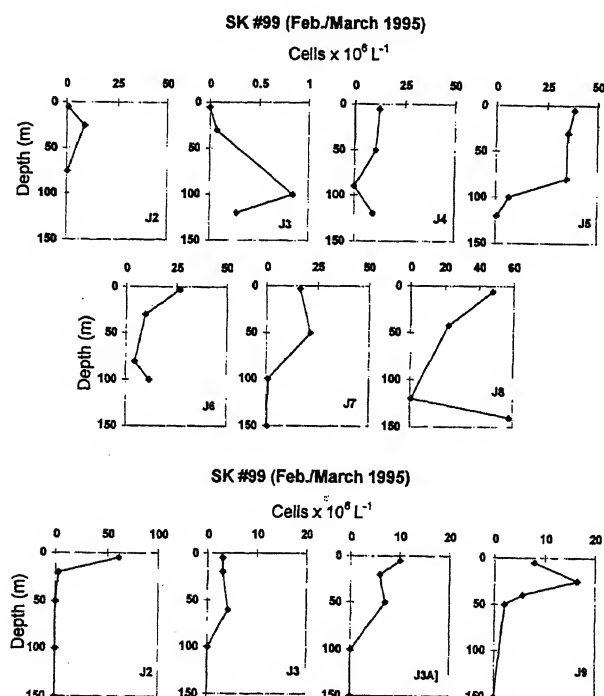

Figure 8. Picoplankton abundance during cruises SK #99 in February 1995 and SK #104 in July/August 1995.

sustain bacteria during oligotrophic conditions.

Bacterial production also was much higher during April/May than during July/August. Although bacterial production is normally about 20% of the primary production, values up to 80% of the primary production have been recorded in equatorial Pacific¹⁷. Our observations indicate that biological production during the premonsoon period of April/May was dominated by bacteria, phytoplankton production often accounting for only about 2% of the BP (Figure 7). This is in contrast to the summer monsoon period, when bacterial production was lower and comprised only about 18% of the phytoplankton production. It is not yet clear from our studies as to why bacterial production increased towards the south during April/May. Chandralata Raghukumar (pers. commun.) observed patches of *Trichodesmium* (red tide) blooms in some stations in this area. It is likely that a vigorous red tide bloom preceding our observations provided DOC to promote bacterial dynamics during this season. Such *Trichodesmium* blooms are common in March–April in the Arabian Sea¹⁸.

Our observations might help to provide an explanation to the zooplankton paradox of the Arabian Sea¹⁹. Zooplankton biomass remains more or less constant throughout the year in the Arabian Sea despite variations

in primary productivity leading to the suggestion that secondary production in the Arabian Sea might be sustained through the 'microbial loop'²⁰ during 'lean' seasons. The rapid bacterial turnover in April/May is an evidence that flagellate and ciliate grazing during this period might be intense and further sustain the zooplankton²¹.

Photosynthetically available radiation in the central and eastern Arabian Sea

T. Suresh, Elgar Desa, R. G. P. Desai, A. Jayaraman* and P. Mehra

National Institute of Oceanography, Dona Paula, Goa 403 004, India

*Physical Research Laboratory, Ahmedabad 380 009, India

In this article, we present the analysis of the photosynthetically available radiation (PAR, 400–700 nm) in the eastern and central Arabian Sea (21°30' N, 64°E to 12°N, 74°E) during February–March, 1995 using data collected with quantum PAR sensor and maritime solar radiation models for clear sky. The peak values observed were in the range of about 1700 to 1830 $\mu\text{mole s}^{-1}\text{m}^{-2}$ or equivalent to about 365 to 435 Wm^{-2} . The radiative transfer models of Gregg and Carder, and Frouin *et al.* were used to investigate the relationship between the quantum and energy of solar radiation available in the PAR region. The average ratio of this quanta per energy was found to be about 4.2 $\mu\text{mole W}^{-1}\text{s}^{-1}$. Aerosol optical depth obtained using the sunphotometer at 498 nm for the region was found to vary from 0.07 to 0.19.

LIFE in the ocean is dependent on the amount of sunlight available. The amount of solar irradiance reaching the ocean surface is important in all disciplines of oceanography. From a physical oceanography point of view, the total incident solar irradiance constitutes a major boundary forcing for ocean circulation and determines meridional heat transport. From the biological point of view, solar irradiance in the photosynthetically active interval PAR, regulates marine primary productivity and therefore the evolution of aquatic ecosystems^{1,2}.

The Arabian Sea is a highly productive oceanic region. One of the goals of JGOFS is to understand the process in controlling the carbon flux in the Arabian Sea. Its unique feature is the regular oscillation of high rates of primary production under relatively constant levels of solar radiation³. Though the sunlight is available on the surface at a wide spectral range, the useful light available in the upper layers of ocean is limited in PAR region in the range of 350–700 nm. PAR is defined in terms of energy (Wm^{-2}) as

$$E_{\text{PAR}}(z) = \int_{350}^{700} Ed(\lambda, z) d\lambda, \quad (1)$$

where $Ed(\lambda, z)$ is the downward spectral irradiance (Wm^{-2}) at wavelength λ (nanometers) at depth z (meters). The total quanta available in the photosynthetic

range is given by

$$Q_{\text{PAR}}(z) = 1/hc \int_{300}^{700} \lambda Ed(\lambda, z) d\lambda, \quad (2)$$

where h is the Planck's constant and c is the velocity of light in vacuum. Q_{PAR} has units of quanta $\text{s}^{-1}\text{m}^{-2}$.

Usually PAR is taken as a constant fraction of total solar irradiance. PAR includes more than 45% of total radiation reaching the earth's surface for low zenith angle or high elevation above 30°.

Materials and methods

During February–March, 1995 PAR values were measured in the eastern and central Arabian Sea (21°30' N, 64°E to 74°E) under the JGOFS (India) programme aboard the research vessel ORV Sagar Kanya (Table 1). Q_{PAR} values were measured using quantum PAR sensor LI-190S (LI-COR Inc., USA) (Figure 1). The sensor was placed at a clear site on a raised platform on the ship to obtain sunlight without any obstruction. The PAR range of this sensor is 400–700 nm. The unit is given in $\mu\text{mole s}^{-1}\text{m}^{-2}$. (1 $\mu\text{mole s}^{-1}\text{m}^{-2} = 6.022 \cdot 10^{17}$ quanta $\text{s}^{-1}\text{m}^{-2}$). E_{PAR} is evaluated using two solar radia-

tion models of Gregg and Carder⁴, and Frouin *et al.*⁵. The meteorological parameters were measured with an automatic logging meteorological station^{6,7}. The atmospheric pressure recorded every minute was averaged over a ten minutes interval, while wind speed, wet and dry bulb temperatures were recorded every 3 hours. A single wavelength hand held sunphotometer was used to obtain the aerosol optical depth (wavelength 498 nm, FWHM = 13 nm). The unit was calibrated using the Langley method at a clear sight at a high altitude station, Mount Gurushikhar.

Since all measurements were made with reference to Indian Standard Time (Longitude 82° 30' E), corrections were applied to obtain the local time at the meridian of observation. In the model, airmass is assumed to be unity, which is typical for maritime atmospheres. Ozone and water vapour contents were not measured. Average values for water vapour were obtained from the atlas of Ramesh Kumar *et al.*⁸, average ozone content was taken as 320 Dobson Units, which gives ozone scale height to

be 0.32 cm. Total precipitable water vapour was taken from the atlas⁹ as 5.5 g cm⁻².

Solar radiation models

Spectral model of Gregg and Carder¹

The high resolution solar spectral irradiance model of Gregg and Carder⁴ was used to evaluate E_{PAR} . This model was adopted as it was suited for maritime atmosphere and it provided spectral information at a high resolution of 1 nm. The model computed contributions from direct and diffuse sunlight available at any time in the range of 350–700 nm. We have used the range of 400–700 nm for compatibility with the quantum sensor output.

Attenuation of solar irradiance in the visible and near-UV wavelengths is attributed to atmospheric processes such as scattering by gas mixture (Rayleigh scattering), absorption by gas mixture, absorption by ozone, and scattering and absorption by water vapour. Irradiance that is not scattered out of the direct beam but toward the surface is the diffuse irradiance. The sum of the direct and diffuse components defines the global irradiance available for use.

$$E_{dd}(\lambda) = F_0(\lambda) \cos(\theta) Tr(\lambda)$$

$$Ta(\lambda) Toz(\lambda) To(\lambda) Tw(\lambda), \quad (3)$$

$$E_{ds}(\lambda) = I_r(\lambda) + I_a(\lambda), \quad (4)$$

where dd and ds refer to direct and diffuse components, $F_0(l)$ is the mean extra terrestrial irradiance corrected for earth-sun distances and orbital eccentricity, θ is the solar zenith angle, Tr , Ta , Toz , To and Tw represent transmittance after absorption or scattering by air molecules, aerosol, ozone, oxygen and water vapour respectively. Similarly I_r and I_a represent the diffuse components due to Rayleigh scattering and aerosol.

For maritime environment, the above equations on incorporating air-sea interactions change to

$$E_{dd}(\lambda) = E_{dd}(\lambda) \cdot (1 - \rho_d), \quad (5)$$

$$E_{ds}(\lambda) = E_{ds}(\lambda) \cdot (1 - \rho_s), \quad (6)$$

where ρ_d is the direct sea surface reflectance and ρ_s is the diffuse reflectance.

Aerosol optical depth

Marine aerosols, being larger than continental aerosols, reduce solar radiation by absorption and large scattering. Total optical depth is a sum of optical depths due to Rayleigh scattering, (τ_R) aerosol extinction (τ_A) and gaseous absorption (τ_G). Total columnar optical depth

Figure 2. Total columnar optical depth at various stations

measured at 498 nm using the sunphotometer (Figure 2) is given as

$$\tau(\lambda) = \tau_R(\lambda) + \tau_A(\lambda) + \tau_G(\lambda). \quad (6)$$

Rayleigh optical depth is expressed as^{10, 11}

$$\tau_R(\lambda) = (p/p_0) 0.00865 \lambda^{-(3.916+0.074\lambda+0.050/\lambda)}. \quad (7)$$

Here λ is given in micrometer, p is the barometric pressure (mb) and p_0 is the standard atmospheric pressure ($p_0 = 1013.25$ mb).

Optical depth component due to ozone is calculated at $\lambda = 498$ nm and is given by $\tau_{O_3}(498) = 0.01$ and contributions due to other gases are assumed to be the same as at 484 nm, whose value is given as, $\tau_G(484) = 0.005$. Using the equation (7) for τ_R at 498 nm and optical depth for gases as given above, we calculate the aerosol optical depth $\tau_A(498)$ at each station. Since no data for optical depth was available at stations 8, for this station we have taken the average value of the total columnar optical depth of 0.3. With the help of aerosol optical depth at 498 nm, we determine the aerosol depths at other wavelengths using the Angstrom formula

$$\tau_A(\lambda) = \beta \lambda^{-\alpha} \quad (\lambda \text{ in } \mu\text{m}). \quad (8)$$

Here β is the turbidity coefficient representing the aerosol concentration and α is the Angstrom component.

Angstrom component α is given in terms of Junge exponent γ as¹³

$$\alpha = -(\gamma + 3). \quad (9)$$

Aerosol size distributions can be expressed by two expressions, Junge distribution¹⁴ and by an expression dependent on relative humidity and wind speed¹⁵. The latter expression is evaluated for three radii of particles, 0.1, 1.0 and 10 nm. Logarithmic regression of these with the three radii is computed and the regression coefficients give the Junge exponent. Using equation (9) we then obtain the Angstrom component. Having obtained α , β can be obtained from equation (8) with the observed value of $\tau_A(498)$. $\tau_A(\lambda)$ is then calculated for all other wavelengths.

Model of Frouin *et al.*

This is a simple, yet accurate analytical formula to determine the PAR at the ocean surface under clear skies⁵. The formula is given as follows

$$E_{PAR} = F_{PAR} T_1 T_2 T_3 \quad (10)$$

F_{PAR} is the monochromatic extraterrestrial irradiance integrated over 400–700 nm, taking into consideration the earth–sun separation.

$$T_1 = \frac{\cos(\theta) \exp[-a+b/V]/\cos(\theta)}{1-\rho(a'+b'/V)}, \quad (11)$$

$$T_2 = \exp[-av(U_v/\cos(\theta))^{bv}], \quad (12)$$

$$T_3 = \exp[-a_0(U_o/\cos(\theta))^{b_0}], \quad (13)$$

ρ is average surface reflectance, V visibility, U the vertically integrated absorbed amount, θ the zenith angle, and subscripts o and v denote ozone and water vapour respectively.

The regression coefficients for maritime atmosphere over spectral region 400–700 nm are given as

$$a = 0.068 \quad b = 0.379 \quad a' = 0.117, \quad b' = 0.493,$$

$$av = 0.002, \quad bv = 0.87 \quad a_0 = 0.052 \quad b_0 = 0.99.$$

Visibility V (km) is calculated using the aerosol optical depth data. Aerosol extinction coefficient at 550 nm is expressed in terms of visibility¹⁶

$$C_a(550) = 3.91/V. \quad (14)$$

This extinction coefficient is related to aerosol optical thickness by

$$\tau_A(550) = C_a(550) H_a, \quad (15)$$

where H_a is the aerosol scale height, which is assumed to be 1 km (ref. 17). We can determine aerosol optical depth at 550 nm using the method described earlier in Gregg and Carder⁴ model.

Results and discussion

The two models were evaluated for eight stations in the Arabian Sea. They were found to agree closely with the real time data collected using a quantum PAR sensor. With the exception of ozone and water vapour contents, all other meteorological parameters required for the models were measured at the stations. The measured peak values of PAR were found to vary from about 1700 to 1830 $\mu\text{mol s}^{-1} \text{m}^{-2}$ or equivalent to about 365 to 435 W m^{-2} evaluated using the solar radiation models. Figure 3 shows the measured and model data given for a station. In the absence of observed meteorological data for the duration of calculation, the last observed values were considered, assuming that variations over the period were not significantly large. The models seem to agree better at stations when there were less disturbances in PAR values, such as at station 11°N, 64°E

(25 February) and 11° 40'N, 74° 20'E (3 March). A discontinuity was usually observed with the quantum sensor data around 1000 hours, which is attributed to the shadow of a mast on the deck while the others at 1300 to 1500 hours probably caused by clouds. Since the models were tuned for clear sky, the observed values were filtered to remove all such spurious data.

We have used the models to analyse the behaviour of $Q_{\text{PAR}} : E_{\text{PAR}}$. The ratio of observed PAR quantum values to the solar irradiance values evaluated using the models of Gregg and Carder⁴ and Frouin *et al.*⁵ were 4.08 and 4.04 respectively (Figures 4 and 5). After filtering the data for disturbances, the ratios were boosted to values 4.24 and 4.20 for the Gregg and Carder and Frouin *et al.* models respectively. The difference in the ratios for both the models was found to be marginal ($< 0.02\%$), when the solar irradiance was estimated for zenith angles below 68°, 80° and 90°. Morel and Smith¹⁸ obtained a value of 2.77×10^{18} quanta $\text{W}^{-1} \text{s}^{-1}$ or 4.6 $\mu\text{mol W}^{-2} \text{s}^{-1}$ for 400–700 nm. ($1 \mu\text{mol s}^{-1} \text{m}^{-2} = 6.022 \cdot 10^{17}$ quanta $\text{s}^{-1} \text{m}^{-2}$). Their observations were for solar zenith angles $< 68^\circ$ and the ratio is for monochromatic radiant energy at 550 nm, the central wavelength of the spectral region 400–700 nm. Baker and Frouin¹⁹ obtained a ratio of 2.68×10^{18} quanta $\text{W}^{-1} \text{s}^{-1}$ or 4.38 $\mu\text{mol W}^{-1} \text{s}^{-1} \text{d} \lambda$ is taken as the central wavelength, in the range 350–700 nm.

Investigation of aerosol content is also part of the study under JGOFS (India) and it is also an important parameter required for remote sensing, validation of algorithms and models. Atmospheric turbidity obtained using sunphotometer at 498 nm was found to vary from

Figure 3. PAR sensor and model data for station 6 (25 March).

Figure 4. PAR sensor data vs solar irradiance model of Gregg and Carder.

Figure 5. PAR sensor data vs solar irradiance model of Frouin *et al.*

0.23 to 0.35. The aerosol optical depth derived from this was found to vary from 0.07 to 0.19.

The analytical model of Frouin *et al.*⁵ was found to be simple compared to the rigorous high resolution spectral model of Carder and Gregg⁴. The model of Frouin *et al.* could be used to obtain the much required parameter of aerosol optical depth. Solar irradiance values in PAR range can be measured using the PAR sensor and the same can be equated to the model of Frouin *et al.*² to obtain the aerosol optical depth.

^{234}Th scavenging and particle export fluxes from the upper 100 m of the Arabian Sea

M. M. Sarin, R. Rengarajan and V. Ramaswamy*

Physical Research Laboratory, Ahmedabad 380 009, India

*National Institute of Oceanography, Dona Paula 403 004, India

We have determined the particle scavenging rates, export fluxes of ^{234}Th and settling particles from the upper 100 m of the Arabian Sea as a part of the JGOFS (India) Programme. The spatial and temporal measurements made in the open ocean profiles reveal close similarities in the dissolved $^{234}\text{Th} : ^{238}\text{U}$ disequilibria, suggesting that the rates of particle-associated scavenging processes are generally uniform in the central Arabian Sea. The observed disequilibrium integrated for the upper 100 m yields a mean scavenging residence time of ~ 30 days and a removal rate of $\sim 3400 \text{ dpm m}^{-2} \text{ d}^{-1}$ for ^{234}Th , from dissolved to particulate phases.

The deficiency of total ^{234}Th (dissolved + particulate) relative to ^{238}U allows us to compute the vertical export flux of particulate ^{234}Th . The flux data for the upper 100 m show spatial variations with enhanced export fluxes centered around 22°N 67°E , a region characterized by higher rates of column primary productivity. Using the ^{234}Th export fluxes and the measured specific activity of ^{234}Th in the sediment traps, we have computed the particle and carbon fluxes at 100 m. These results reveal that the particle fluxes determined from sediment traps are systematically low and the estimated C export fluxes are grossly out of proportion with the column primary production.

THE reactive nuclides of the U–Th decay series, viz. ^{234}Th , ^{210}Po and ^{210}Pb serve as valuable tracers for studying the rates of particle-associated chemical scavenging processes, particle export from the euphotic zone and new production in the ocean. These tracers are introduced in the water column as dissolved species (by radioactive decay of their parent nuclides dissolved in seawater) and are redistributed between the dissolved and particulate phases depending on their particle reactivity and availability of particle surfaces. The latter depends on the rates of primary production, particle transformation and their net downward export. Bhat *et al.*¹ were the first to demonstrate the application of ^{234}Th – ^{238}U disequilibrium to study the particle scavenging processes in oceanic surface waters. These studies were later expanded by Coale and Bruland^{2,3} and suggested that the scavenging rates of reactive elements may vary as a function of new production rather than total primary production. Recently, Buesseler *et al.*^{4,5} have used the profiles of ^{234}Th and a non-steady state scavenging model

to quantify the particulate ^{234}Th fluxes and to derive export fluxes of particulate carbon and nitrogen from the euphotic zone. Likewise, the ^{210}Po – ^{210}Pb disequilibrium in surface waters and the particulate release of ^{210}Po at ~ 100 m have been modelled to derive the new production rates in the Arabian Sea⁶.

Measurements of particle export fluxes using sediment traps in the top few hundred meters of the water column have also been compared with those derived based on the $^{234}\text{Th} : ^{238}\text{U}$ disequilibrium studies^{7–9}. These studies have shown significant discrepancy for the trap fluxes suggesting that the shallow traps do not always provide a reliable measure of the particle export. We report here our results on the ^{234}Th scavenging and particle export fluxes in the eastern-central Arabian Sea during the JGOFS (India) cruises. We have used the ^{234}Th and ^{238}U isotope data from unfiltered (total) samples and the specific activity of ^{234}Th in the sediment trap material to derive the particle export fluxes.

Samples and analyses

Samples were collected during ORV *Sagar Kanya* cruises No. 91 (April–May 1994), No. 99 (February–March 1995) and No. 104 (July–August 1995) in the Arabian sea (Figure 1). Three stations sampled during April–May 1994 at 11°N , 15°N and 22°N along the 64°E transect were reoccupied during the subsequent cruises to study the temporal and spatial variations in the export fluxes of ^{234}Th and settling particles. The hydrographic data (potential temperature, salinity and depth) were simultaneously measured at all stations. Parallel measurements of primary productivity were also made using *in-situ* incubations¹⁰.

Unfiltered seawater samples from the upper 300 m water column were collected using 30 litre Go-Flo bottles fitted on the CTD rosette and were analysed for ^{234}Th , ^{238}U , ^{210}Po and ^{210}Pb . At selected stations, along the 64°E transect (Figure 1), samples were also filtered through $0.4 \mu\text{m}$ pore size Nuclepore filters (47 mm diameter) directly attached to the Go-Flo bottles. All these nuclides were pre-concentrated from about 20–25 litres of either filtered or unfiltered seawater with $\text{Fe}(\text{OH})_3$ in presence of chemical yield tracers. Subsequently, radiochemical separation and purification of these

nuclides were achieved following the procedures of Sarin *et al.*¹¹.

The mass flux of settling particles at 100 and 300 m depths was measured using free-floating sediment traps deployed, during April–May 1994 (cruise-91) and February–March 1995 (cruise-99), for a period of 3–5 days at station sites 15°N, 64°E and 21.5°N, 64°E. The multi-traps (Hydrobios, Germany) consisting of a PVC cylinder (having collection area 0.01515 m² and aspect ratio of 1:4) fitted to six polyethylene bottles were used in this study. After recovery of the traps, supernatant water in the sample bottles was carefully decanted and 'swimmers' were removed. Samples were then filtered through 0.4 µm Nuclepore filters and dried at 40°C. One-half of the collected material was analysed for ²³⁴Th, ²¹⁰Po and ²¹⁰Pb. For this, filters were acid digested (HCl + HNO₃) in presence of yield spikes and analytical procedures follow that of Sarin *et al.*¹¹. The remaining half of the filters were stored for the analysis of organic carbon.

Results and discussion

In this article we present the data on the dissolved and total (dissolved + particulate) ²³⁴Th concentrations; results on the ²¹⁰Po and ²¹⁰Pb will be presented elsewhere. The distribution of dissolved and total ²³⁴Th activities vs depth at the three stations along the 64°E transect is shown in Figure 2. The vertical profiles of total ²³⁴Th measured at stations along the coast are presented in Figure 3. The errors ($\pm 1\sigma$) in the ²³⁴Th activities are

Figure 1. Stations sampled during three cruises: SK-91 (April–May 1994), SK-99 (February–March 1995) and SK-104 (July–August 1995). Reoccupation of the stations during different seasons, along the 64°E transect, is shown as an offset. Locations of trap deployment is shown by diamond symbol.

about $\pm 5\%$ arising from counting statistics, tracer calibrations and blank corrections. The accuracy and precision of our ²³⁴Th measurements were checked by analysing unfiltered seawater samples collected from 1000 to 2000 m depths. The ²³⁴Th/²³⁸U activity ratios measured in these samples were in close agreement to the expected equilibrium value. The ²³⁸U activity (Figures 2 and 3) was calculated based on its relation with salinity [²³⁸U (dpm/kg) = (0.06969) × S‰] derived for the Arabian Sea¹¹. This relation is based on measured ²³⁸U and salinity data for samples collected from surface to 2000 m depth including those from sub-oxic regions. The ²³⁸U concentration did not show any distinct decrease in the samples from denitrification region^{6,11}.

²³⁴Th scavenging

The dissolved activity of ²³⁴Th, at all sampling depths

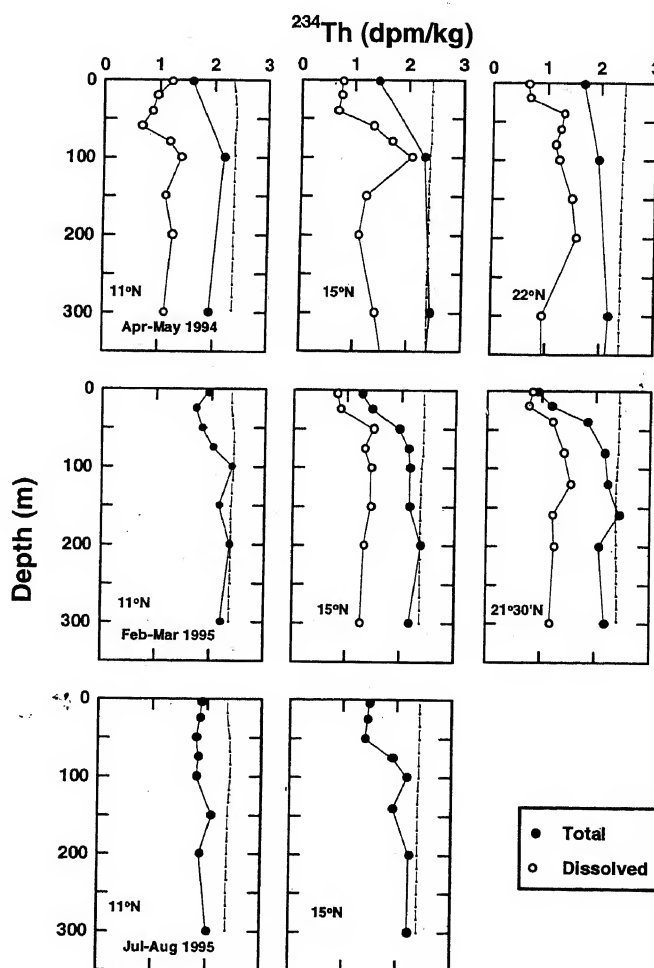

Figure 2. Vertical profiles of dissolved and total (dissolved + particulate) ²³⁴Th activities in the upper 300 m at three open ocean stations along the 64°E transect. The dash line represents the dissolved activity of the parent isotope ²³⁸U. A gross deficiency of ²³⁴Th is clearly evident in the surface 100 m.

(Figure 2), shows a pronounced deficiency with respect to its parent ^{238}U whereas total ^{234}Th shows near-equilibrium concentration at $>100\text{ m}$. The deficiency of dissolved ^{234}Th is attributed to its removal from the dissolved to particulate phases. The dissolved $^{234}\text{Th} : ^{238}\text{U}$ activity ratio in surface waters at three stations along the 64°E , during April–May (summer), ranges from 0.28 to 0.43; with lowest value occurring at the northern-most station. However, the column deficiency of dissolved ^{234}Th integrated over 0–100 m is quite similar at all the three stations. These results yield a mean residence time of about 30 days for dissolved ^{234}Th in the surface 100 m with respect to its removal onto particles. The nearly identical extent of dissolved $^{234}\text{Th} : ^{238}\text{U}$ disequilibrium suggests that the rates of particle-associated scavenging processes in the central Arabian Sea are quite uniform and are not resolvable based on ^{234}Th distribution.

These three stations along the 64°E transect were reoccupied during winter (February–March, Figure 1). The overall pattern of dissolved ^{234}Th distribution and the extent of $^{234}\text{Th} : ^{238}\text{U}$ disequilibrium during the winter

months is nearly the same as that measured during the summer. The mean dissolved $^{234}\text{Th} : ^{238}\text{U}$ activity ratio in the surface 100 m at these three stations is 0.49 (Figure 2), which yields ^{234}Th scavenging residence time of 34 days, quite similar to that observed during summer. This result is surprising considering that the water column (0–100 m) productivity¹⁰ at these sites during winter ranged from 335 to 643 $\text{mg C m}^{-2} \text{ d}^{-1}$, which is about 2–3 times higher than that during April–May. The scavenging residence time of ^{234}Th during the summer and winter seasons is quite similar to that reported by Sarin *et al.*¹² at nearby locations. These results imply that the temporal variations in chemical scavenging rates of ^{234}Th in surface waters of the central Arabian Sea are not significantly influenced by the primary production and that the steady-state conditions assumed in the tracer scavenging model are nearly valid. Furthermore, our results from the Arabian Sea do not follow the linear trend between ^{234}Th scavenging rate and the primary productivity as reported by Coale and Bruland² for the Gulf of California.

The total ^{234}Th activity (dissolved + particulate) measured in the unfiltered samples also shows a pronounced deficiency with respect to ^{238}U in the upper 100 m water column (Figures 2 and 3). This deficiency of total ^{234}Th is attributed to its scavenging and subsequent downward export via settling particles. The mean residence time of ^{234}Th , with respect to its decay and removal from the water column, is about 100 days. Below 100 m, the total activity of ^{234}Th at stations along the 64°E transect is close to secular equilibrium value (Figure 2). In

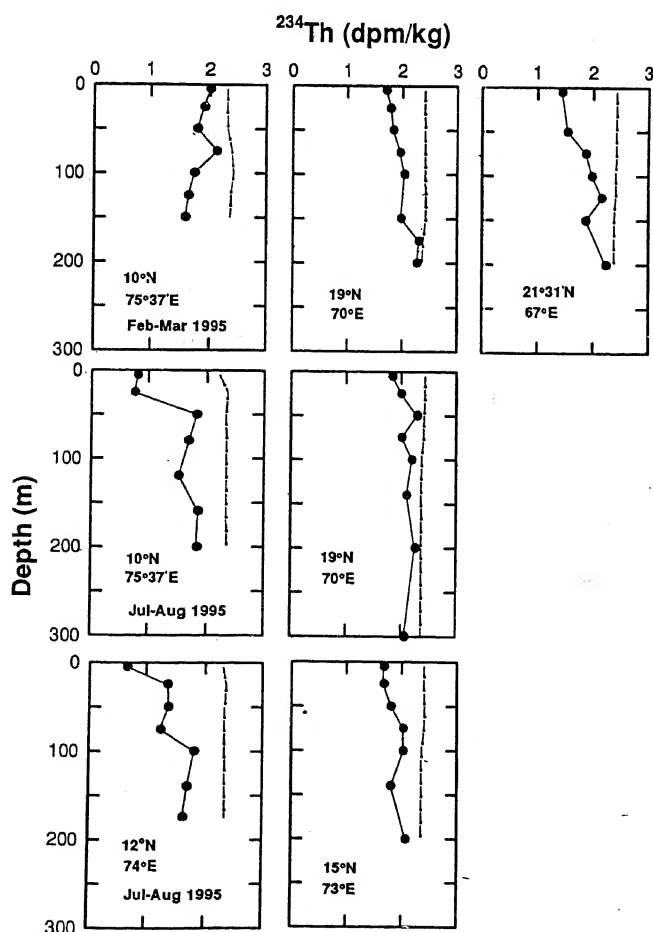

Figure 3. Activity of total ^{234}Th at coastal stations is plotted with respect to ^{238}U (dash line) indicating significant deficiency all through the water column.

Figure 4. ^{234}Th export fluxes computed from the water column profiles as a function of primary production rate. Linear relation is seen for the data (filled squares) during winter (February–March). Data for summer (April–May) is shown by filled circles. Primary productivity data are from Bhattathiri *et al.*¹⁰

contrast, the total ^{234}Th activity at stations along the coast shows marked deficiency down to 200 m depth (Figure 3). One possible explanation for this is the higher particulate concentration in coastal waters and the rapid uptake of ^{234}Th near the sediment-water interface. At some of the coastal stations, this deficiency is relatively enhanced all through the water column during the monsoon period (July–August).

We have computed the removal rate of ^{234}Th from dissolved to particulate phases for two stations, viz. 22°N and 15°N (along the 64°E transect) based on the dissolved activities of ^{234}Th and ^{238}U measured during April–May and February–March (Figure 2). The average rate at which dissolved ^{234}Th is scavenged onto particles in the surface 100 m is estimated to be about $3400 \text{ dpm m}^{-2} \text{ d}^{-1}$. This rate for the central Arabian Sea is comparable to that reported for the California Current². The inventories of total ^{234}Th (dissolved + particulate) in the surface 100 m for the open ocean profiles, along the 64°E transect, are quite similar $(17 \pm 1)10^4 \text{ dpm m}^{-2}$ during the three sampling seasons (Table 1). The total ^{234}Th inventories vary from 12.4×10^4 to $19.7 \times 10^4 \text{ dpm m}^{-2}$ at the coastal stations (Table 1).

^{234}Th export

The measured deficiency of total ^{234}Th with respect to dissolved ^{238}U (Figures 2 and 3) has been modelled to derive the vertical export of particulate ^{234}Th from the upper 100 m water column (Table 1). The export fluxes at the coastal stations range from 915 to $2750 \text{ dpm m}^{-2} \text{ d}^{-1}$. At open ocean stations, ^{234}Th export rates show a north–south trend with higher values for the northernmost stations (Table 1). However, the derived export fluxes at an individual station are quite similar during

the summer (April–May) and winter (February–March) but tend to be somewhat higher during monsoon (July–August, Table 1).

The ^{234}Th export fluxes computed for the open ocean stations show a linear trend with the integrated column (0–100 m) primary productivity (Figure 4). This relationship, however, seems to be limited for the data from the same season. For example, the ^{234}Th export fluxes during February–March vary from 1125 to $2170 \text{ dpm m}^{-2} \text{ d}^{-1}$ while the column productivity varies from 200 to $860 \text{ mgC m}^{-2} \text{ d}^{-1}$. Although these export fluxes are somewhat identical with those during April–May (Table 1), the primary productivity is about a factor of three higher during the winter cruise (February–March 1995). These results suggest that the use of ^{234}Th as a survey tool for primary productivity needs close scrutiny.

Particle export

The particulate ^{234}Th export fluxes (at 100 m) based on water column deficiency are distinctly higher than those measured directly using floating sediment traps (Table 2), particularly in the samples collected during winter. During the winter season, the ^{234}Th flux measured by traps at 100 m is about a factor of four lower than that expected (assuming no lateral transport of particulate Th) from the water column deficiency (Table 2). Similar results are obtained based on the ^{210}Pb flux measured in the trap material and that expected from the atmospheric fallout¹³. This suggests that the shallow traps underestimate the particle export flux and the carbon export fluxes determined using them, without appropriate corrections for trapping efficiency, are likely to be underestimated. Similar observations were made by Bueseler *et al.*⁴ during the North Atlantic Bloom Experiment.

*Calculated based on the observed ^{234}Th : ^{238}U disequilibrium.

For deriving the particle export rates (Table 2), we have corrected for the trapping efficiency by assuming it to be the ratio of the measured ^{234}Th flux in the traps to that expected from its water column deficiency. It is also implicit here that the measured ^{234}Th flux in the traps deployed over 3–5 days is representative of the site.

Analogous calculations for the total material fluxes, from the upper 100 m column, have been made for other sampling sites in the Arabian Sea (Table 3). The particle export fluxes, corrected for trapping efficiency, range from 1890 to 3280 $\text{mg m}^{-2} \text{d}^{-1}$ during winter and are about a factor of 2 to 3 higher than those during summer. In each case, particle fluxes are obtained by dividing the estimated ^{234}Th export (Table 1) by ^{234}Th specific activity (dpm/g) measured in the traps (Table 2). The measured ^{234}Th activity in the trap material during April–May and February–March is 1856 and 662 dpm/g, respectively, and it is assumed to be rep-

resentative of all the sites during the respective season. A decrease in the specific ^{234}Th activity by a factor of 3 during winter could be related to the dilution of trap material by the increased abundance of particles/aggregates. This is in agreement with the measured $\text{C}/^{234}\text{Th}$ ratio during February–March (Table 2) when the column productivity is 2–3 times higher than that during April–May. Buesseler *et al.*⁴ have suggested that the temporal changes in $\text{C}/^{234}\text{Th}$ could occur as a function of local primary production and export balance. Relatively high $\text{C}/^{234}\text{Th}$ ratios were observed during bloom conditions in the North Atlantic⁴. We observe an increase in the $\text{C}/^{234}\text{Th}$ ratio from 0.24 during summer to 0.52 (mg/dpm) during winter suggesting that an enhanced vertical transport of sinking particles are ^{234}Th deficit. The organic carbon to total mass ratio in the traps is somewhat comparable between summer and winter, 0.43 and 0.35 respectively. This observation further reinforces the view that the dilution of trap material is most likely the cause

for the decrease in particulate ^{234}Th activity during winter.

As proposed by Eppley¹⁴, the other purpose of studying ^{234}Th – ^{238}U disequilibrium and particle export of ^{234}Th , in the upper 100m, is to relate it to carbon export flux out of the euphotic zone. The C export flux has been computed as a product of the ^{234}Th export flux (Table 3) and C/ ^{234}Th ratio for the corresponding period (Table 2). The calculated flux is distinctly higher than the measured C export at the trap site during winter (Table 2), suggesting that an appropriate correction for particle trapping efficiency is needed for the reliable estimates of C using floating sediment traps. In general, estimated C export fluxes at all stations are higher than the column primary productivity (Table 3). There could be two explanations for the estimated C fluxes being higher than the primary productivity: (i) there is an additional source of carbon via the microbial loop and that the C/ ^{234}Th measured in the trap material (collected over 3–5 days period) is not representative of the site and water column POC inventory, or (ii) there is a phase lag between primary production and flux out of the euphotic zone. We propose the first explanation to be more dominant as there is an evidence for active microbial pathway¹⁵. Also, C/ ^{234}Th ratio of the settling particles in the trap may not be appropriate for estimating organic C export. Indeed the direct measurement of C flux in the traps during April–May is also higher than the primary production (Table 2). These observations raise the question of differential cycling of the various components of particulate matter and ^{234}Th in the upper 100 m of the Arabian Sea.

Conclusions

The ^{234}Th : ^{238}U disequilibrium in the upper 100 m has been used to derive the chemical scavenging rates and the export fluxes of ^{234}Th and settling particles in the Arabian Sea. In the open ocean, the residence time of dissolved ^{234}Th with respect to its removal onto particles is ~ 30 days. We find that the estimated vertical export fluxes of particulate ^{234}Th (at the respective sites) are similar between summer and winter and that the export fluxes are higher in general over the regions characterized

by higher rates of column productivity. The ^{234}Th flux data are used to derive the fluxes of particulate matter and carbon at 100 m. The computed fluxes of particles are significantly higher than those measured using free-floating sediment traps. The C export fluxes are also higher than the column primary productivity suggesting that the direct comparison of these fluxes with independent estimates of new production is needed. The future studies should aim towards understanding the relationship between C and ^{234}Th on sinking particles and dynamics of carbon cycling in the Arabian Sea.

ACKNOWLEDGEMENTS. This study was funded by the Dept of Ocean Development, New Delhi, as a part of the JGOFS (India) programme. We thank Prof. S. Krishnaswami for helpful suggestions and discussions during the course of this study. Thanks are also due to the scientific party and crew members of the ORV *Sagar Kanya* cruises (No. 91, 99 and 104) for their shipboard assistance. We thank Drs. Ken Buesseler and T. M. Church for their critical reviews of the manuscript.

Distribution of nitrous oxide and methane in the Arabian Sea

Shyam Lal, Prabir K. Patra, S. Venkataramani and M. M. Sarin

Physical Research Laboratory, Ahmedabad 380 009, India

Measurements of the two important biogenic gases N_2O and CH_4 have been made both in the water column and in air of the Arabian sea during April–May 1994 and February–March 1995, as part of the JGOFS (India) programme. The average abundances of N_2O and CH_4 in the air are 313 ± 7 ppbv and 1.69 ± 0.05 ppmv respectively. During both the periods, the vertical profiles of N_2O in the water column show a double peak structure with the dominant peak in the 500–1000 m depth region with concentrations of 70–80 nmol. The entire water column is supersaturated with respect to N_2O and in the major peak region it is supersaturated by as much as 600–800%, suggesting this region of the Arabian sea to be an important reservoir of N_2O . During February–March 1995, sea–air flux of N_2O is calculated to be about $0.26 \text{ pg cm}^{-2} \text{ s}^{-1}$, while the flux calculated for April–May 1994 is not significantly different from zero. Methane concentrations were measured only down to 400 m depth. Its distribution shows a peak concentration of 6–8 nmol in the 100–200 m depth region. Supersaturation (up to 200–400% at the peak) is found for CH_4 in most of the profiles. Average sea–air flux of methane during April–May 1994 and February–March 1995 is 0.0001 and $0.033 \text{ pg cm}^{-2} \text{ s}^{-1}$, respectively.

Nitrous oxide (N_2O) and methane (CH_4) are important minor constituents of the earth's atmosphere. Recently, N_2O is being studied with growing interest due to its greenhouse warming potential¹ and as a source of NO radicals in the stratosphere which participates in the catalytic ozone depleting reactions². N_2O emanates from the earth's biosphere due to various natural and anthropogenic activities, the latter include biomass burning, fertilizer use and land use. It is estimated that the oceans also contribute significantly (20–30%) to the global budget¹ of N_2O . Recent studies in the Arabian Sea show a significant ocean to atmosphere flux of N_2O in spite of its relatively small area (0.43%) of the world oceans^{3,4}.

Methane plays an important role in controlling the abundance of atmospheric water vapour and hydroxyl radical⁵, and it also takes part in tropospheric ozone chemistry and greenhouse warming. Major sources of methane to the atmosphere are wetlands, paddy fields and enteric fermentation¹. In general, oceans are a relatively minor source of methane. Sub-surface ocean water has been found to be supersaturated at different loca-

tions^{6–8}. Under the Joint Global Ocean Flux Study (India) programme, these trace gases have been measured both in air and in the water column during April–May 1994 (cruise No. SK-91) and February–March 1995 (cruise No. SK-99) in the north-east Arabian Sea (11°N–22.5°N, 64°E–74°E). In this article we describe the results and provide estimates of the sea–air fluxes of N_2O and CH_4 .

Experimental procedure

Measurements of N_2O and CH_4 were made using two gas chromatographs (GCs) installed on board the ORV *Sagar Kanya*. N_2O was measured using a Varian VISTA series gas chromatograph equipped with an electron capture detector (GC-ECD). The ECD is widely used to measure nitrous oxide and various kinds of halo-carbons^{9–11} due to its high sensitivity and sufficient linear response¹². A $5 \text{ m} \times 0.32 \text{ cm}$ stainless steel column packed with Porapak-Q (80/100 mesh), maintained at 40°C, was used for N_2O analysis. A Shimadzu GC equipped with a flame ionization detector was used for measuring CH_4 . A stainless steel column of dimension $5 \text{ m} \times 0.32 \text{ cm}$, packed with molecular sieve-13X maintained at 60°C was used. Atmospheric pressure inside the laboratory was recorded using an MKS baratron sensor for pressure correction.

Air samples were collected in 50 ml B–D plastic syringes from the bow of the ship while cruising (i.e. between stations). Samples were injected into the GC column after passing through a moisture trap and using a 4 ml loop connected to a 6 port valve. Both these were flushed with the same sample before final injection. Each sample was run 2–3 times to obtain representative concentrations. Sea-water samples were collected from various depths using 1.7 l Niskin bottles during SK-91 cruise and 30 l Go-Flo bottles fitted to a CTD Rosette during the SK-99 cruise. During April–May 1994, water samples were collected down to a depth of 3000 m at several stations, but during February–March 1995 the depth of sampling was restricted to a maximum of 1000 m. Samples were drawn from these bottles into 50 ml glass bottles and stored in a refrigerator until analysis. Most of the sample analyses were completed within 24 hours of collection using standard techniques. 25 ml of water sample and 25 ml pure He were equili-

brated in a B-D syringe for about 5 minutes at room temperature. 4 ml of this equilibrated He was injected on to the GC column after passing through a moisture trap filled with $\text{Mg}(\text{ClO}_4)_2$. A similar procedure was followed for CH_4 analyses except that in this case 30 ml of sea water was equilibrated with 20 ml of pure He. Duplicate samples were analysed periodically to check for reproducibility of results and to evaluate the precision of measurements. The replicate measurements were found to be within 10%. A 50 l cylinder filled with air (from PRL, Ahmedabad) was used as the laboratory standard which was analysed frequently to check for stability of the instruments. This standard was calibrated for N_2O and CH_4 using standard mixtures of known concentrations. The concentrations of N_2O and CH_4 in the standard air were estimated to be 313 ppbv and 1.94 ppmv respectively.

Concentrations and fluxes

Concentrations of N_2O and CH_4 in air are calculated by comparing the GC response with the response obtained from the laboratory standard. The mole concentrations of dissolved gases in sea water are calculated based on the principle of multiple phase equilibrium as given by McAuliffe¹³. For example, the concentration of N_2O in sea water in nmol can be expressed as

$$\text{N}_2\text{O (nmol)} = 0.0409 \times \frac{1}{H_x} \times P_L \times \frac{298}{T_L} \times \text{N}_2\text{O (ppbv)}, \quad (1)$$

where H_x is Henry's law constant, which is a function of temperature and salinity, P_L and T_L are the laboratory pressure (atm) and temperature (K) respectively, N_2O (ppbv) is the mixing ratio of nitrous oxide in the zeroth order equilibrated air with sea water, and the constant (0.0409) is the conversion factor from mixing ratio (ppbv) to concentration (nmol) at STP. This concentration is defined as observed concentration (C_{obs}). A similar equation is used for calculating the methane concentration.

Saturation concentrations (C_{sat}) of the respective gases in water were calculated by multiplying their partial pressure in the ambient marine air with their solubility in sea water at the appropriate temperature and salinity. The solubility of N_2O and CH_4 in sea water was calculated by using the relations of Weiss and Price¹⁴ and Atkinson and Richards¹⁵, respectively. The flux (F) in $\text{nmol cm}^{-2} \text{s}^{-1}$ between air and water was calculated by using the wind speed dependent transfer velocities¹⁶ and can be expressed as

$$F = k \times \Delta C, \quad (2)$$

where ΔC is the difference in concentrations ($= C_{\text{obs}} - C_{\text{sat}}$) and k is the gas transfer velocity in cm h^{-1} . The value of k depends on wind velocity and is evaluated using one of the following equations

$$k = 0.17 U_{10} (660/S_c)^{2/3} \quad U_{10} \leq 3.6$$

$$k = (2.85 U_{10} - 9.65) (660/S_c)^{1/2} \quad 3.6 < U_{10} \leq 13 \quad (3)$$

$$k = (5.9 U_{10} - 49.3) (660/S_c)^{1/2} \quad U_{10} > 13.$$

U_{10} is the wind speed (m s^{-1}) at 10 m height from the sea surface, S_c is the Schmidt number of the respective solute gas, calculated using the expressions given by Wanninkhof¹⁷. Note that the constant 660 which is the Schmidt number of CO_2 at 20°C in sea water has been used instead of 600, which is for the freshwater, as proposed in a more recent analysis¹⁷. A negative flux value suggests ocean as a sink for the solute gas whereas a positive value implies ocean to be a source to the atmosphere.

Results

Latitudinal distributions in the concentrations of N_2O measured in air during SK-91 and SK-99 along 64°E are shown in Figure 1. The data show a significant scatter, from about 300 to 335 ppbv without any systematic trend. The average concentration was found to be 313 ± 7 (1σ ppbv). The spread ($\pm 1\sigma$) is similar to analytical precision (2%), however, the error in absolute concentrations could be larger ($\pm 5\%$) due to calibration uncertainties. Figure 2 shows typical distributions of N_2O in sea water down to 3000 m depth during the SK-91 cruise. The concentration of N_2O increases very sharply from about 6 nmol in the surface water to about 50 nmol at around 150–200 m depth. At depths between 200 and 300 m, there is a decrease in the concentration particularly in the northern latitudes. N_2O concentration increases again to values as high as 60–80 nmol at around 700 m depth; below which it decreases with depth to a value of 20 nmol at around 3000 m. Figure 2 also shows the expected concentrations of N_2O for 100% saturation (dotted line). It is evident from Figure 2 that N_2O is at or above saturation throughout the water column. At the major peak (500–1000 m), supersaturation is in the range of 600% to 800%. Even at 3000 m depth the value ranges between 130% and 160%. Similar general features in the vertical distribution of N_2O have also been observed in the profiles measured during subsequent cruise (SK-99).

Figure 3 shows a contour plot of N_2O concentrations for the latitude region of 11 to 22°N measured during SK-91. The distribution shows three high N_2O concentration regions centered at 13°N , 17°N and 22°N with

values as high as 77 nmol, with the maximum values occurring at deeper depths in higher latitudes; at 13°N it is located around 500 m depth while at 22°N it is at ~900 m depth. Along 64°E longitude the shallower peak is more intense towards northern latitudes. Although

somewhat similar features have been reported during measurements made in December 1988 in the Arabian sea along 67°E longitudinal transect⁴, such detailed structures have not been observed. A comparison of N₂O concentrations in sea water obtained during the two

Figure 1. Distribution of nitrous oxide in the Arabian Sea air measured along the cruise track during April–May 1994 (SK-91) and February–March 1995 (SK-99).

Figure 2. Examples of the vertical distribution of N₂O in the water column along 64°E longitude.

Figure 3. Distribution of nitrous oxide (nmol) showing the latitudinal variability down to 3000 m depth observed during SK-91 cruise.

cruises is shown in Figures 4a and 4b. A broad maximum around 17–18°N latitude and 800 m depth was seen during both the cruises. However, the finer scale features in the shallow depths (0–600 m) are different. The two low N_2O regions which were located around 500 m depth during SK-91 were observed at a shallower depth (300–400 m) during SK-99. During both these cruises higher concentrations of N_2O were observed, centered around 17°N, between these two minima.

Figure 5 shows methane concentrations in air during SK-91 and SK-99 cruises. The results show marginally higher CH_4 concentrations (1.70) during SK-91 than those (1.66) during SK-99, with an average value of 1.69 ± 0.05 ppmv for the combined data of both the cruises. The spread is within the range of analytical

errors. Measurements of methane in the water column were made for the north of 16°N of the cruise track during SK-91 and along the complete track during SK-99. Typical concentration profiles observed during SK-99 are shown in Figure 6. The concentration of methane in the surface water was observed to be about 3 nmol, increasing to value of 4–9 nmol at around 100–200 m. Below this depth, its concentration decreased gradually to 2–4 nmol. Methane is supersaturated at almost all depths from the surface down to 400 m depth. Supersaturation at the maximum concentration varied from 200 to 400%.

There is a large variability in methane distribution from open ocean to the coast. In the shallow coastal waters, the maximum CH_4 concentration was higher. The vertical profiles of CH_4 as depicted in Figure 6 for 16°N and 18°N represent features of the open ocean, the one at 22°N shows characteristics of a coastal region. Prior to these studies, the only other reported measurements of CH_4 in the Arabian Sea were due to Owens *et al.*⁷ These results also showed a supersaturation of CH_4 , however, the nature of the CH_4 profiles, particularly the depth of CH_4 maximum differs in these two studies. Figures 7a and 7b show the spatial and depth variations of methane concentration along the 64°E meridian. The major peak in methane was observed at 19°N around 150 m depth during SK-91 whereas the peak was found to be at shallower depth (~125 m) during the later cruise (SK-99). It can also be seen that the depth of

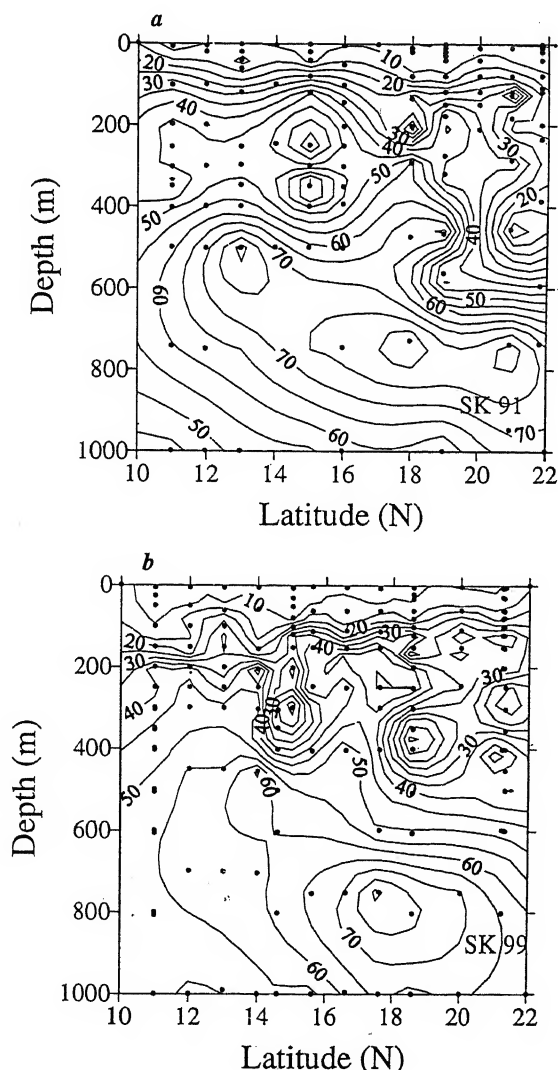

Figure 4. Distribution of nitrous oxide (nmol) showing latitudinal distribution down to 1000 m depth for SK-91 (a) and for SK-99 (b). All contours are shown at an interval of 5 nmol.

Figure 5. Mixing ratios of methane as observed in marine air during SK-91 and SK-99 cruises.

Figure 6. Examples of the vertical distribution of CH_4 (nmol) in the water column during SK-91 cruise.

methane maximum decreases with increase in latitude (Figure 7b). Thus at 11°N the methane maximum occurs at a depth of about 200 m, while at 19°N it is observed at around 125 m depth (Figure 7b).

The sea-air fluxes of CH_4 and N_2O have been computed using equations (2) and (3) described earlier. Fluxes from or into sea water depend upon the degree of saturation in surface water and the wind speed. There is no significant supersaturation of N_2O in the surface water during SK-91 (April–May 1994). The N_2O content in surface water during this period is within $\pm 10\%$ of the concentration expected from the partial pressure in air, however, an average flux of about $0.003 \text{ pg cm}^{-2} \text{ s}^{-1}$ can be calculated. The range of ΔC in surface waters during this cruise is within errors ($\pm 1\sigma$) of measured N_2O concentrations. However, during SK-99 (February–March 1995), there is a distinct supersaturation of N_2O in surface water, leading to an average ocean-air N_2O flux of about $0.26 \text{ pg cm}^{-2} \text{ s}^{-1}$. Our values are within the range of earlier reported values of $0.44 \pm 0.22 \text{ pg cm}^{-2} \text{ s}^{-1}$ (September–October, 1986)³ in north-west Arabian Sea and $0.23 \pm 0.1 \text{ pg cm}^{-2} \text{ s}^{-1}$ in the north-east Arabian Sea⁴.

The average methane flux from the surface water into the atmosphere was estimated to be about 0.0001 ± 0.006 (1σ) $\text{pg cm}^{-2} \text{ s}^{-1}$ during SK-91, while during SK-99 the average flux was found to be about $0.033 \pm 0.046 \text{ pg cm}^{-2} \text{ s}^{-1}$. Owens *et al.*⁷ measured methane fluxes in the range of 0.08 to $0.26 \text{ pg cm}^{-2} \text{ s}^{-1}$ (0.46 to $1.4 \text{ nmol cm}^{-2} \text{ day}$). Low values of both N_2O and CH_4 fluxes measured during April–May 1994 period are due to lesser degree

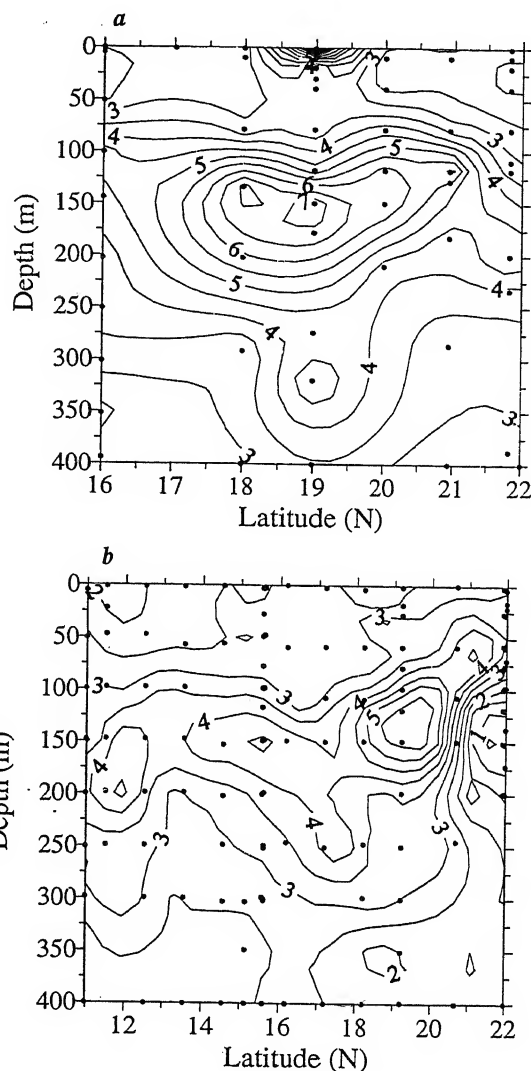

Figure 7. Latitudinal depth contour plots of methane (nmol) observed during SK-91 (a) and during SK-99 (b). Alternate contours are labelled.

of supersaturation and lower wind speed prevailing in the Arabian Sea.

Discussion

The distributions of N_2O with depth in water show two peaks. The shallow peak in the 150–200 m depth region is more pronounced in the northern region, beneath which is a concentration maximum in the 500–1000 m depth. Below this maximum the concentration gradually decreases with depth, down to 3000 m. The low concentrations between the two peaks coincide with the secondary nitrite maximum resulting from denitrification. In this region N_2O itself is reduced by the bacteria. Both nitrification and denitrification are considered to be the processes responsible for the production of N_2O .

in sea water^{4,9,10,18,19}. Besides the supersaturation of N₂O in the entire water column, large latitudinal and longitudinal variations were observed. During the SK-91 cruise (April–May 1994) there is no appreciable N₂O sea–air flux, whereas during SK-99 (February–March 1995) an average flux of about 0.26 pg cms is estimated. During SK-91, the sea surface conditions were more quiet and there was no clear supersaturation in surface water which lead to insignificant flux of this gas across the boundary. During SK-99 period, wind speeds were relatively higher and the waters were relatively more supersaturated. The mixed layer depth (MLD) was much deeper during SK-99, in the range of 70 to 120 m while during SK-91 it ranged between 20 and 35 m (ref. 20). A higher MLD is likely to give rise to higher concentration due to mixing with deeper N₂O and CH₄ rich water. The MLD was observed to be deepest at 16°N during SK-91 and at 17°N during SK-99 where high N₂O concentrations were observed to be protruding upwards. Compared to the results of present measurements Law and Owens³, and Naqvi and Noronha⁴ have observed significantly different fluxes of N₂O to the atmosphere in September–October 1986, and December 1988 respectively which, in general, suggest strong seasonal dependence of its fluxes.

Measurements of CH₄ are made for the first time in the north-eastern part of the Arabian Sea. These data show maximum concentrations in the region of 100 to 200 m depth. Owens *et al.*⁷ in their studies in western Arabian Sea observed the peak to be located at around 60–100 m depth. This difference is attributed to the deeper Chlorophyll *a* layer in the eastern region (~60 m)²¹ than in the western region (30–40 m)⁷ of the Arabian Sea. During both cruises the methane fluxes to the atmosphere have been observed, with higher fluxes in the SK-99 period. Owens *et al.* observed methane fluxes ranging from 0.08 to 0.26 pg cm⁻² s⁻¹ in the western Arabian Sea, considerably higher than those observed in other oceanic regions⁸ and this study.

ACKNOWLEDGEMENTS. This study was conducted as part of the JGOFS (India) programme supported by a grant from the Department of Ocean Development (DOD), Govt of India. We thank Prof. S. Krishnaswami and Prof. B. H. Subbaraya for encouragement and discussions. We are thankful to Messrs T. K. Sunil and M. Dixit for helping in measurements and members of NIO for providing necessary supporting data and help towards sampling. We also thank the referees for their comments and suggestions.

Manganese mobilization from the Western Continental margin of India

D. N. Yadav

Physical Research Laboratory, Ahmedabad 380 009, India

The Western Continental margin of India (WCMI) exhibits distinct features with respect to vertical distribution of manganese in sediments. There is no significant manganese downcore variation in upper slope sediments whereas high concentration (by an order of magnitude relative to bottom sections) has been observed in top sediment cores for the lower slope region. Also, in the upper slope sediments, average manganese concentration is low by a factor of three compared to that (~1000 ppm) transported by the Narbada/Tapti river suspended particles. The low manganese concentration is attributed to its reductive mobilization. Typical value of manganese flux being mobilized into overlying seawater from reducing upper slope sediments covering an area of 5°Lat × 3°Long is calculated to be 3×10^{10} g/y, which is nearly 10% of dissolved manganese supply to the ocean by world rivers. Although calculated flux of manganese mobilized from upper slope sediments is not the highest among the values from other margin regions, yet this shows a potential source for dissolved manganese in seawater. Interestingly, the calculated carbon oxidation flux (based on manganese reduction rate) in the upper slope sediments is found to be less than 1% of primary productivity and, thus it provides a limiting value of organic matter combustion. Contrary to upper slope sediments, there is no significant supply of soluble manganese to overlying seawater, which is expected due to prevailing oxidizing conditions at the sediment-water interface in the lower slope region.

The biogeochemical cycle of Mn in marine environment plays an important role in regulating trace metal distribution, as manganese oxides are potential scavengers of several trace metals¹. In sediments, Mn oxides undergo reduction to soluble Mn^{2+} during anaerobic decomposition of organic matter^{2,3}.

Therefore, in reducing conditions Mn is released from sediments to pore waters and is subsequently transported to overlying seawater by advective-diffusion processes either in part or completely depending on the redox conditions near the sediment-water interface. In this mobilization process, only some fraction of Mn (reactive component) associated with continental/riverine sediment

inputs is mobilized, leaving behind some fraction in the sediments. At some places of margin regions⁴, high concentration of Mn is reported in top oxidizing sedimentary layer as it acts as a cap for Mn^{2+} escape from below the sediments. These are the major pathways of Mn cycling in margin regions. Release of Mn^{2+} from reducing sediments and thereafter supply to overlying seawater generally takes place if manganese oxidation rate at sediment-water interface is slower than that of its reduction rate in the sediment below the surface⁵⁻⁷. Factors controlling release of Mn^{2+} from sediments to overlying seawater and its distribution in various layers within the sediments include not only the bottom water O_2 concentration⁸⁻⁹, temperature and organic input^{3,7} but also depend on precipitation of authigenic carbonate mineral phases such as calcite¹⁰⁻¹² and Mn-carbonate¹³⁻¹⁴ from the pore waters. Carbonate mineral phases in the sediment can act as a sink for soluble Mn^{2+} . Also, sediments characterized by bioturbation show increased supply rate of Mn^{2+} to the overlying seawater^{5-9,15}.

Earlier studies in sediments from the Western Continental margins of India (WCMI) have shown depletion of Mn along the open shelf and slope regions^{16,17}. More recently, Somayajulu *et al.*¹⁸ attributed variations in the concentrations of manganese in sediments from the shelf and slope regions of WCMI to be due to differences in prevailing redox conditions. This paper synthesizes available data on the manganese distribution in WCMI sediments to obtain constraints on its fluxes to the overlying water column and its role in mineralization of organic matter.

Materials and methods

Five spade sediment cores (50 × 30 × 20 cm) from the WCMI region (Figure 1) were collected during December 1988. Of these, three cores (L-8, J-7 and I-5) are from the upper slope region (water depth ranging from 280 to 350 m) where the core of denitrification layer (centered at ~300 m depth)¹⁹ meets the sediment-water interface. The remaining two cores, viz. K-11 and M-12 are from the lower slope region where water depth is ~2500 m. Immediately after collection, sub-cores of ~5 cm diameter and ~30 cm in length were taken from these spade cores. The sub-cores were sampled at 1–2 cm

depth intervals for CaCO_3 , loss on ignition (LOI), major, trace elements and radionuclide measurements. Intense H_2S smell was felt during sectioning of the cores L-8 and J-7 at about ~ 5 cm below the surface, indicating strong anoxic conditions prevailing near the surface of these cores. On the contrary, no H_2S smell was felt from any layer while sectioning the cores from the lower slope region. Chronology of these cores was determined mainly by the $^{210}\text{Pb}_{\text{excess}}$ and ^{137}Cs methods^{17,18}.

Results and discussion

It is well documented that in anoxic marine sediments, where sediment accumulation is relatively high, manganese is mobilized as Mn(II) from the solid phase to solution²⁰⁻²². In margin areas, the primary source of Mn to sediments is land-derived. Hence, one of the approaches to obtain information on Mn mobilization is to compare the abundance of Mn in margin sediments with that in fluvial sediments. Such study has an important implication to elucidate high content of manganese in deep ocean sediments. In fact, early sediment diagenesis leading to recycling of manganese from near-shore region is considered to be an important 'source' for high manganese concentration in deep ocean reservoir. For instance, suggestion has been made by several workers that a 'source' of Mn to the central North Pacific may be from reduced continental shelf sediments²³⁻²⁷. In the following, manganese mobilization that occurs across the transect encompassing both anoxic (upper slope) and oxic (lower slope) sedimentary environments of the Arabian sea are discussed.

Upper slope sediments (L-8, J-7 and I-5)

The depth profiles of manganese in these sediments are

Figure 1. Map showing core locations (*) along the WCMI with water-depth contours in km.

presented in Table 1 and Figure 2a, though they have been published earlier^{17,18}. The manganese concentration in all these cores is generally low (~ 285–350 ppm, Table 1a) compared to that in the Narbada and Tapi river suspended particles (~ 1000 ppm)¹⁶. The low Mn concentration in these sediment cores relative to the source material is attributed to the reductive mobilization of Mn from the sedimentary column. As the upper slope sediments are from shallow water depths, manganese mobilization from fluvial sediments and particulates during their transit through anoxic denitrification water layer is expected to be minimal. With this assumption, a simple calculation is done to estimate the flux of Mn being mobilized from the upper slope reducing sediments.

The flux of manganese mobilized from sedimentary column, F_{Mn} ($\mu\text{g}/\text{cm}^2 \cdot \text{y}$), can be obtained using the relation

$$F_{\text{Mn}} = S \cdot \rho (C_r - C_s), \quad (2)$$

where S is the sediment accumulation rate (cm/y), ρ the in-situ density (g/cm^3) of the sediment, C_r and C_s are the manganese concentrations in river particles (~ 1000 ppm)¹⁶ and in upper slope sediments. The value of F_{Mn} for the three cores L-8, J-7 and I-5 is calculated to be 7.4, 68.7 and 17 $\mu\text{g}/\text{cm}^2 \cdot \text{y}$ respectively using their column average Mn concentration (Table 1a), density (0.44, 0.58 and 0.61 g/cm^3) (refs 28, 29) and rate of sediment accumulation (0.025, 0.183 and 0.039 cm/y)^{18,28}. In this method of flux calculation for manganese, there is some degree of uncertainty associated with the assumption of constant Mn concentration (~ 1000 ppm) in river-borne suspended sediments. Earlier study has shown that Narbada and Tapi rivers which drain into the study region show a slight seasonal variation in manganese concentration of suspended particles (Narbada: 1000–

Figure 2. Downcore variation of Mn abundance in the lower slope sediments. The Mn distribution in the lower slope sediments shows a distinct structure with high values near the sediment–water interface.

1300 ppm, Tapti: 1200–1300 ppm)¹⁶. With this uncertainty, a typical value of manganese flux from upper slope reducing sediments to overlying seawater can be taken as $21 \mu\text{g}/\text{cm}^2 \cdot \text{y}$, which is the geometric mean of Mn fluxes for three cores. If this calculation is extended to an area of $5^\circ\text{Lat.} \times 3^\circ\text{Long.}$, bounded by these cores, the flux of Mn would be $\sim 3.0 \times 10^{10} \text{ g/y}$ which is nearly

10% of the dissolved Mn ($\sim 3 \times 10^{11} \text{ g/y}$) transported by world rivers to ocean²⁷. Such a high flux of Mn out of sediments from the upper slope region of the Arabian Sea emphasizes the importance of mobilization of Mn in the margin region. It is likely that manganese released from these sediments is a source of dissolved Mn maxima reported in the Arabian Sea intermediate waters³⁰⁻³¹. In order to evaluate the importance of manganese mobilization from reducing sediments as 'source' for seawater, benthic chamber study is necessitated³².

Table 2 compares the flux of Mn released from river-borne particles from the upper slope sediments of the Arabian Sea with the fluxes reported from other coastal margin areas of the world ocean. The flux of Mn solubilized is generally related to rates of sedimentation, biological productivity and also to the particle mixing by bioturbation⁴. Sundby and Silverberg³³ have studied manganese cycling in Laurentian trough (water depth, 300–400 m) and applied a diagenetic model and mass-balance calculations to derive the Mn flux. They observed a net flux of $140\text{--}180 \mu\text{g}/\text{cm}^2 \cdot \text{y}$ (Table 2). The magnitude of particle mixing by bioturbation considerably influences the rate of Mn cycling both in the sediment core (internal cycling) and the fraction mobilizing to overlying seawater. Trefry and Presley³⁴ have interpreted the deficiency of Mn in the Mississippi delta sediments, compared to that in the river particulates, as due to its mobilization under reducing conditions. Using the concentration gradient of Mn in sediment pore waters, they calculated the outgoing diffusive manganese flux from sediments (water depth < 100 m) in the range of $30\text{--}850 \mu\text{g}/\text{cm}^2 \cdot \text{y}$ (Table 2). Johnson *et al.*³² have

Table 2. The benthic manganese flux from margin sediments

Margin sites	Mn flux ($\mu\text{g}/\text{cm}^2 \cdot \text{y}$)	Reference
WCMI (upper slope)	~ 35	This study,
Central California coast line	~ 10	Johnson <i>et al.</i> ¹⁴
Gulf of St. Lawrence	~ 140–180	Sundby and Silverberg ³³
Mississippi Delta	~ 30–850	Trefry and Presley ³⁴
Eastern Bering shelf	~ 1	Heggie <i>et al.</i>

reported an average benthic Mn flux of $\sim 10 \mu\text{g}/\text{cm}^2 \cdot \text{y}$ from the central California continental margin.

In the present study, the estimated high flux of manganese, $21 \mu\text{g}/\text{cm}^2 \cdot \text{y}$ from the upper slope region of WCMI (Table 2), points out the importance of WCMI in controlling the overall marine budget of manganese in seawater. In this regard, more rigorous and quantitative information on manganese flux calculation is necessitated by studying concentration gradient of manganese in sediment pore waters.

Lower slope sediments (K-11 and M-12)

The manganese distribution in the two cores, K-11 and M-12, from the lower slope region shows features, which are distinctly different from those observed in the upper slope sediment cores. These two cores have high Mn concentrations (~ 1900 and 10160 ppm on CaCO_3 free basis) occurring in surface sections (Figure 2 b, Table 1 b)^{18,28}. In core M-12 the Mn concentration decreases with depth and attains a value of 900 ppm, for K-11 the Mn concentration shows a shallow depth ($4\text{--}5$ cm) maximum and then decreases to a value of ~ 700 ppm below 10 cm depth. Such a distribution of Mn is typical of the slope sediments where Mn released at depths in the sedimentary column by diagenetic processes is sequestered at the oxic sediment–water interface^{15,33,35}. In contrast to the average value of Mn for upper slope sediments, the median value (Median of Mn concentration has been taken owing to large downcore variations in manganese data, see Figure 2 b) of Mn concentration (on a CaCO_3 free basis) taken over the entire core length for K-11 and M-12, is ~ 1340 and ~ 1270 ppm respectively. These values of Mn are comparable with that of fluvial sediments transported by the Narbada/Tapti rivers¹⁶. These data suggest that there is no net mobilization of Mn, but only its redistribution within the column.

A model calculation has been done to determine manganese reduction rate, which in turn provides carbon oxidation flux for the lower slope sediments in the column itself. For this, out of the two cores, only M-12 could be modelled using the concept of Aller^{5,15}, because required exponential function for manganese distribution could be fitted with this core. In the following, discussion

is made on application of Aller model^{5,15} to elucidate oxidation of C_{org} based on Mn distribution in the core M-12.

In the lower slope sediments, the depth profile of 'excess' Mn concentration can be represented by particle mixing and Mn reduction rate as proposed by Aller⁵. This is represented by

$$\frac{\partial C_s}{\partial t} = D \cdot \frac{\partial^2 C_s}{\partial z^2} - R = 0, \quad (3)$$

where D is the mixing coefficient, C_s is the solid-phase 'excess' Mn concentration and R is the Mn reduction rate. For shorter core length, say about 5 cm, D is generally assumed to be constant^{5,15}. Also, an assumption is made that manganese mobilized by reduction–oxidation process is internal, and there is no leakage of Mn^{2+} to the overlying water. The 'excess' manganese [i.e. total solid-phase Mn minus the average background (background Mn concentration refers to unreactive Mn which remains almost constant after a certain depth from the surface) value in $\mu\text{g}/\text{g}$] in top ($0\text{--}4$ cm) of the core M-12 is converted in units of mass/volume ($\mu\text{M}/\text{cm}^3$) by using *in-situ* sediment density of $0.33 \text{ g}/\text{cm}^3$ and its depth profile is fitted with an exponential function⁴:

$$C_s = C_0 \cdot e^{-\beta \cdot z}, \quad (4)$$

where C_s and C_0 are the solid phase Mn concentration at any depth and at the sediment surface respectively and β is the attenuation coefficient. Attenuation constant

Figure 3. Experimental data for the sediment core M-12 fitted with the exponential function for different values of β (see text for explanation).

Figure 4. Schematic diagram showing Mn cycling between sediment and seawater along the WCMI region that represents $5^\circ\text{Lat.} \times 3^\circ\text{Long.}$ area. C_r is concentration and F_r the flux of Mn transported by riverine suspended matters. C_s and F_s refer to concentration and flux of Mn mobilized from reducing upper slope sediments to the denitrification layer. C_{sl} is the average concentration of Mn in lower slope sediments. Although dissolved riverine Mn input and atmospheric transport are neglected, a reasonable degree of balance is observed between F_r and $(F_s + F_{Mn})$.

(β) controls decay profile of 'excess' manganese concentration with depth which is dependent on particle mixing and bioturbation. The best fit with experimental data by the exponential function (with varying β) is shown in Figure 3. It is clear from the figure that the most suitable β value for Mn distribution in the core is 0.1 cm^{-1} . The only unknown in eqn (3) is D for determining (R), the Mn reduction rate. Assuming that the exponential depth profile of $^{210}\text{Pb}_{\text{excess}}$ in top 10 cm of M-12 is solely due to particle mixing (assumption seems to be reasonable since bioturbation is important for lower slope sediments owing to prevalence of oxic conditions at the sediment-water interface), the mixing coefficient D (ref. 36) is calculated to be $0.18 \text{ cm}^2/\text{y}$ which is an upper limit for particle mixing in the core M-12. This value of mixing coefficient is within the range ($0.04\text{--}0.4 \text{ cm}^2 \cdot \text{y}^{-1}$) (ref. 37) often cited for deep sea sediments.

Using this value of D and exponential function for 'excess' Mn concentration in eqn (4) which results R , the Mn reduction rate, integral of R over the depth interval for which 'excess' Mn is observed, yields an average Mn reduction flux of $0.33 \mu\text{M}/\text{cm}^2 \cdot \text{y}$. This information on Mn reduction flux is related to C_{org} oxidation flux within the sedimentary column, the details of which are given below.

The manganese reduction in nearshore sediments is represented by the following relation⁹

This shows that two moles of Mn^{2+} are generated during the oxidation of one mole of C_{org} . Therefore, it

is possible to estimate the amount of C_{org} oxidized from the Mn^{2+} released based on this stoichiometry. Such an estimate in the present study would be an upper limit for the amount of organic carbon mineralized because of two reasons: (i) uptake of Mn^{2+} by manganese carbonate precipitation in sediments from pore waters^{13,14} is neglected, and (ii) reduction of Mn oxides by abiotic/inorganic reactions³⁸ is ignored.

Considering manganese reduction flux of $0.33 \mu\text{M}/\text{cm}^2 \cdot \text{y}$ and following eqn (5), the flux of organic carbon oxidized in lower slope sedimentary column is $\sim 0.16 \mu\text{M}/\text{cm}^2 \cdot \text{y}$. Similarly, based on estimate of Mn flux (range, $7\text{--}69 \mu\text{g}/\text{cm}^2 \cdot \text{y} \equiv 0.1\text{--}1.0 \mu\text{M}/\text{cm}^2 \cdot \text{y}$) mobilized from the upper slope, the oxidation rate of C_{org} is calculated to be in the range of 0.05 to $0.5 \mu\text{M}/\text{cm}^2 \cdot \text{y}$. Comparing this flux with the primary production ($\sim 1500 \mu\text{M C}/\text{cm}^2 \cdot \text{y}$) as reported for upper slope region³⁹, it implies that the reduction of Mn contributes to $<1\%$ oxidation of C_{org} fixed by the photosynthetic activity. This indicates that C_{org} oxidation up to a stage of Mn reduction in sediments from the upper slope region may be a lower limit for organic matter combustion. More extensive study of this kind is required over the Arabian Sea region to establish relationship between manganese reduction rate and the carbon oxidation flux at the sediment-water interface. The results obtained from this study have direct relevance to the objectives of the ongoing JGOFS (India) programme.

The manganese cycling between solid and aqueous phases along the WCMI has been shown in Figure 4. A reasonable degree of balance is observed between the flux of manganese transported through Narbada/Tapti riverine sediments ($F_r \sim 5.8 \times 10^{10} \mu\text{g/y}$) and the sum of

fluxes that mobilized into seawater and the net burial rate of Mn ($F_s + F_{Mn} \sim 5.3 \times 10^{10} \mu\text{g/y}$) in the upper slope sediments. F_s , the net burial flux of manganese is calculated by assuming typical concentration of ~ 300 ppm, density of 0.5 g/cm^3 and rate of sediment accumulation 1 mm/y for the upper slope region. Furthermore, an assumption is made that contribution of Mn from its dissolved component through rivers and atmospheric transport is negligible. Figure 4 shows that the median value of Mn over the core length for the lower slope sediments is comparable with that of river suspended particles and average crustal rock composition. Thus, isopycnal transport of soluble manganese from upper slope sediments to oxidizing lower slope sediments, as is expected, is not a significant phenomenon. In the lower slope sediments, therefore, most likely the manganese cycling is internal in nature and its depth profile is controlled by microbial diagenetic processes.

ACKNOWLEDGEMENTS. Discussions with Profs S. Krishnaswami, B. L. K. Somayajulu and Dr M. M. Sarin were beneficial to the author during the course of this study. The critical reviews from Drs P. M. Saager and Tom Church greatly helped in improving the manuscript. Finally, I thank the Department of Ocean Development, New Delhi for generous help in funding the project.

Conformation of ATPMg(II) bound at the specific site on bovine serum albumin: ^1H -nuclear magnetic resonance study

Hari Pada Maity and Gotam K. Jarori*

Tata Institute of Fundamental Research, Homi Bhabha Road, Colaba, Mumbai 400 005, India

Bovine serum albumin (BSA) binds one molecule of adenosine 5'-triphosphate (ATP) at one of the fatty acid-binding sites. Interaction of ATPMg(II) with BSA and its conformation in the bound form has been investigated using ^1H -nuclear magnetic resonance (NMR). Binding of nucleotide with albumin results in downfield shift of all the ligand proton resonances, indicating the involvement of adenine as well as ribose moiety in binding interactions. Measurements of change in chemical shifts of H2, H8 and H1' protons of the ATP in the bound form as a function of ligand concentration, has yielded a dissociation constant of $K_d \sim 2$ mM for ATPMg(II) with albumin. Two dimensional transferred nuclear Overhauser spectroscopy (TRNOESY) was used to determine the inter-proton distances in ATPMg(II) bound to BSA. In order to select a concentration range of the ligand where binding occurs exclusively at the specific site, we have measured the NOE intensities for H1'-H2' protons as a function of ATP concentration. For determining the conformation of bound ATPMg(II) at the specific site, NOE intensities have been measured for several mixing times ($\tau_m = 40$ –200 ms). The resulting NOE buildup curves were analysed using complete relaxation matrix calculations to determine various inter-proton distances. Examination of amino-acid sequence of BSA has led to the identification of a region GVKGLSRS (aminoacyl residues 425–432) which is very similar to the consensus sequence present in several ATP-binding proteins. On the basis of observed similarities in the conformation of bound ATP with that of other ATP-utilizing enzymes and the presence of the nucleotide binding consensus sequence, we propose that the specific ATP binding site is located on Domain-III of BSA.

SERUM albumin is one of the most abundant non-glycosylated proteins in the blood plasma. It contributes about 80% of the colloidal osmotic pressure which provides the driving force to keep fluid within blood vessels^{1,2}. The most unique feature of the albumin is its ability to bind a wide variety of biological materials. This includes divalent cations, a variety of metabolites, hormones, drugs, free fatty acids, etc.^{1,3,4}. Several of these functions depend on the extraordinary ability of albumin

to bind hydrophobic as well as hydrophilic compounds. Recent X-ray studies on human serum albumin complexed with different ligands have shown that the principal ligand binding sites were located in subdomains IIA and IIIA (ref. 5). Several aromatic compounds bind at these two sites. Their general orientation in the binding cavity depends upon the nature of substitutions in the aromatic ring.

In a recent study Bauer *et al.*⁶ used a number of spin labelled derivatives of ATP and studied their binding to bovine serum albumin (BSA) using the electron spin resonance method. It was found that ATP binds at a specific site on BSA with a stoichiometry of 1:1 and a dissociation constant in the range of 50–100 μM . BSA is known to bind about 4–5 moles of fatty acids per mole of protein^{7,8} and it is proposed that nucleotide interacts at one of these amphipathic regions on the surface of the protein⁶. ATP with an aromatic ring (adenine), a hydrophilic sugar moiety (ribose) and a highly charged triphosphoryl tail, appears to be an excellent probe to characterize the specific binding site on the albumin. With this in view, we have studied the interaction of ATPMg(II) with BSA using NMR. The ability of NMR to observe every ligand proton has allowed us to identify the regions of the ligand which are in direct contact with the protein in the protein-ligand complex. Further, the conformation of the bound nucleotide has been determined, using proton transferred nuclear Overhauser effect spectroscopy (TRNOESY)^{9–11} in 2D-NOESY mode¹² and has been compared with those of other nucleotide-binding proteins^{13–23}.

Materials and methods

Materials

Bovine serum albumin was purchased from Armour Pharmaceutical Company. ATP, 4.9 M – MgCl_2 solution and D_2O (99.96 atom% D) were obtained from Sigma. Chelex-100 was supplied by Bio-Rad. Tris(hydroxymethyl)aminomethane- d_{11} (99.0 atom% D) (Tris- d_{11}) was purchased from ISOTEC Inc, USA. All other chemicals were of Analar grade and used without purification.

*For correspondence.

Sample preparation

Bovine serum albumin was dissolved in 20 mM sodium phosphate, pH 7.5, and dialysed against the same buffer. The solution was treated with Chelex-100 to remove trace metal ions. H₂O was exchanged with D₂O by dialysing the sample against 20 mM sodium phosphate, pH 7.5, (without any isotopic correction) in a dialysis cell. At least ten changes of buffer were made for solvent exchange. This was lyophilized once and then dissolved in 99.96% D₂O. The concentration of BSA was determined spectrophotometrically with $A_{280} = 0.66 \text{ mg}^{-1} \text{ ml cm}^{-1}$ and molecular weight of 66,000 Daltons²⁴. Nucleotide solution was also passed through Chelex-100 column, lyophilized and dissolved in D₂O. The concentration of ATP was determined using $A_{259} = 15.4 \text{ mM}^{-1} \text{ cm}^{-1}$.

NMR measurements

¹H-NMR measurements were made on a Bruker-AMX500 NMR spectrometer. In all the measurements, sample temperature was maintained at 10°C. Chemical shifts were measured relative to the internal standard, sodium trimethylsilyl propionate-2,2,3,3-d₄ (TSP). 1D-¹H NMR spectra were recorded with 16 K data points, 6024 Hz spectral width, 2 s relaxation delay and 64 transients were averaged for each spectrum. NOESY time domain data were acquired with 256 t_1 increments and 2 K t_2 points in the phase sensitive mode with the use of TPPI²⁵. Sixty-four scans were averaged for each t_1 increment. Measurements were made with mixing times 40, 80, 120, 160 and 200 ms. The carrier frequency was placed at the HDO resonance in all the experiments. The solvent resonance was suppressed by irradiation using the decoupler channel during intervals of relaxation delay, the t_1 period, and the mixing time. The acquisition parameters were, 1.5 s relaxation delay, 0.17 s acquisition time, and 6024 Hz sweep width.

Data were processed on an Aspect-X32 computer with Bruker software. All the data were processed identically with a two-dimensional Fourier transformation along both dimensions with a Gaussian apodization and a zero filling in t_1 to obtain 1 K (F1) × 2 K (F2) real data points. The spectra were phased to pure absorption mode. The volume of the cross peaks was determined by integration. Percentage of NOEs was derived by dividing the observed cross peak volume by the diagonal peak volume of H1' extrapolated to zero mixing time and then multiplying it by 100. In experiments where measurements were made only for a single mixing time, the diagonal intensity of H1' in the same spectrum was used to determine the per cent NOE.

Determination of binding constant

In an equilibrium between a macromolecule E and ligand L ,

the dissociation constant is given by

$$K_d = [E][L]/[EL].$$

For a given value of K_d , E_T and L_T , where E_T and L_T are the total concentrations of the macromolecule and the ligand; the mole fraction of the bound ligand (P_M), i.e. $[EL]/[L_T]$ can be derived easily. Further, if the binding of L to E results in a change in chemical shift of L resonance by $\Delta\omega$, then under conditions of fast exchange it can easily be shown that

$$\Delta\omega = P_M \Delta\omega_M,$$

where $\Delta\omega_M$ is the chemical shift of the fully bound form of the ligand with respect to its position in unbound form²⁶. Thus, the measurement of the change in the chemical shift where a fixed concentration of macromolecule is titrated with varying concentrations of the ligand, can be analysed by two parameter iterative fit to derive the values of K_d and $\Delta\omega_M$.

Relaxation matrix calculations

Simulations of complete NOE buildup curves in a TRNOESY experiment are greatly simplified if the fast exchange condition prevails²⁷, i.e. the 'on' and 'off' rates of the ligand must be faster than the typical cross relaxation rates^{21,28}. In the limits of fast exchange, the intensity of the $i \leftarrow j$ cross peak represents a polarization transfer from spin j to i , for a mixing time τ_m and is given by^{18,20,21}

$$m_{i \leftarrow j}(\tau_m) = (e^{-R\tau_m})_{ij} M_{oj} \quad (1)$$

$$= [1 - R\tau_m + \frac{1}{2} R^2 \tau_m^2 - \frac{1}{6} R^3 \tau_m^3 + \dots]_{ij} M_{oj}, \quad (2)$$

where M_{oj} is the equilibrium value of the j spin magnetization and R is an average relaxation matrix given by

$$R = p_b W^b + p_f W^f, \quad (3)$$

where p_b and p_f are bound and free fractions of ligand each containing n -spins^{27,29,30}, W^b and W^f are the dipolar interaction^{27,31-34} terms between two protons in bound and free form respectively and are given by

$$W_{ij} = W_{ji} = \frac{\gamma^4 \hbar^2 \tau_c}{10 r_{ij}^6} \left[-1 + \frac{6}{1 + 4\omega^2 \tau_c^2} \right] \quad (4)$$

and

$$W_{ii} = \frac{\gamma^4 \hbar^2 \tau_c}{10} \left[1 + \frac{3}{1 + \omega^2 \tau_c^2} \frac{6}{1 + 4\omega^2 \tau_c^2} \right] \sum_{k \neq i} r_{ik}^{-6}, \quad (5)$$

in which γ and ω are the gyromagnetic ratio and Larmor frequency of the protons, r_{ij} is the distance between spins i and j , and τ_c is the isotropic rotational correlation time. Equations (4) and (5) assume that the spin system is in a single conformation characterized by distance r_{ij} , and undergoing isotropic rotational diffusion characterized by the τ_c . Equation (2) shows that, for short mixing times, the build-up of the intensity of a cross peak in a TRNOESY spectrum, given by $m_{i \leftarrow j}(\tau_m)$ vs τ_m , is a polynomial in τ_m , and the initial slope of the build-up which is just the linear term, yields R_{ij} . Since usually $\tau_c^b > \tau_c^f$, p_b/p_f is 0.1–0.15, the last term in equation (3) is negligible so that

$$R_{ij} = P_b W_{ij}^b. \quad (6)$$

From equations (4) and (5) it can easily be shown that the ratio of initial slopes for different spin pairs is related to the corresponding internuclear distances in the bound conformation as

$$(R_{ij}/R_{ik}) \approx (r_{ik}^b/r_{ij}^b)^6. \quad (7)$$

Here $r_{ij}^b = 2.90 \pm 0.2 \text{ \AA}$ is the calibration distance between H1' and H2'. This distance is known to be independent of the nucleotide conformation^{15,35}. The inter-proton distances derived using equation (7) were used as initial distances and a comprehensive analysis of data was done using equations (1) and (2) to obtain an iterative fit between theory and experiment.

Energy minimization and molecular modelling

Molecular modelling and restrained energy minimization were performed using Insight II (V2.3.0) in the software package, Discover (V2.9.5) supplied by Biosym Technologies. The software was run on Iris Indigo work station supplied by Silicon graphics computer systems. The calculations were performed on adenosine molecule in vacuum. The inter-proton distances derived after complete relaxation matrix calculations were used as restraints allowing $\pm 10\%$ variation in the distance. The energy was minimized using steepest descent method followed by conjugate gradients method available with the software package.

Results and analysis

Binding of ATPMg(II)

In $^1\text{H-NMR}$ spectrum of ATPMg(II), resonances due to H2, H8, H1' (see Figure 1 for nomenclature of various protons in ATP) are observable at 8.51, 8.22 and 6.14 ppm respectively. Binding of ATPMg(II) to BSA results in downfield shift of all the three resonances. The H2 proton resonance of adenine ring exhibits the largest shift. A sample containing 0.50 mM BSA in 25 mM Tris- $\text{d}_{11}\text{-Cl}$, pH 7.5, and 25 mM MgCl_2 , was titrated with ATP in the concentration range of 0.43–4.73 mM. The observed change in the chemical shift of a proton was measured in Hz, from the corresponding resonance of ATPMg(II) in the absence of BSA. Largest downfield shift was observable at the lowest concentration of ATP. With increasing concentration of ATP, the resonances tend to shift towards the unbound ATP positions. Such behaviour is characteristic of a fast exchange condition where the rate of exchange of a ligand between bound and free environment is faster than that of the difference in chemical shift in two states. The data from this experiment have been analysed (as described above) to determine the dissociation constant for ligand binding (K_d) and the change in chemical shift for various protons in the bound form ($\Delta\omega_M$). Figure 2 presents the observed change in chemical shift measured from the respective free ligand resonance as a function of mole fraction of the bound ligand. The dissociation constant (K_d) derived for ATPMg(II) is $2.00 \pm 0.15 \text{ mM}$. Downfield shift of H2, H8 and H1' resonances in bound form with respect to free form are 191 ± 12 (0.382 ppm), 76 ± 6 (0.158 ppm), and 66 ± 5 (0.132 ppm) Hz respectively. In a simple case of two site exchange, if ω_A and ω_B are the resonance frequencies at the two sites (free and bound respectively) in the absence of exchange and τ_A and τ_B are the corresponding lifetimes at the two sites when exchange occurs, the fast exchange condition³⁶ can be defined by

$|\omega_A + \omega_B| = \Delta\omega_M < \tau_A^{-1}, \tau_B^{-1}$. Since the τ_B is the lifetime of ligand in *EL* complex, τ_B^{-1} represents the rate of dissociation of ligand (k_{off}) from the complex. Thus, it can be shown that under fast exchange condition, $\tau_B^{-1}(k_{\text{off}}) > \Delta\omega_M (2\pi\Delta\nu)$. The largest change in chemical shift of H2-proton in the bound form allows us to set the lower limit for the rate of dissociation of ligand from the complex (k_{off}), that is $k_{\text{off}} \gg 1200 \text{ s}^{-1}$.

Dependence of NOE on ligand concentration

Figure 3 presents a typical NOESY spectrum of BSA.ATPMg(II), where several ligand inter-proton NOEs are observable as off diagonal peaks. To observe the site-specific NOEs arising due to interaction of ligand at the site of interest, appropriate sample conditions must be determined¹⁸. We have measured TRNOESY spectra with a mixing time of 120 ms at several different concentrations of the ligand. In each case the ratio of protein to ligand was maintained at 1:10. Note that protein concentration will also vary along with the ligand. Separate samples were prepared for each ATP concentration to avoid errors due to dilution. Figure 4

Figure 2. A plot of observed downfield change in chemical shift (Hz) of H2, H8 and H1' protons of ATP measured from the respective free resonances, as a function of bound ATP mole fraction ($[\text{BSA.ATPMg(II)}]/[\text{ATP}]_T$). Sample contained 0.50 mM BSA; 20 mM MgCl_2 ; 25 mM Tris-(d_{11})-HCl pH 7.5 and the ATP concentration was varied from 0.43 to 4.73 mM. The spectra were recorded at 500 MHz, 10°C with a digital resolution of 0.35 Hz. The points are experimental and the solid curves are computed with a $K_d = 2.0 \text{ mM}$ for BSA.ATPMg(II) complex and the difference in chemical shift for bound and free resonances to be 191 ± 12 , 76 ± 6 and $66 \pm 5 \text{ Hz}$ for H2, H8 and H1' protons respectively.

shows a plot of per cent NOE for H'-H2' (distance between these two protons is invariant, irrespective of the nucleotide conformation) as a function of ATP concentration. Initial increase in per cent NOE to ~2% for a ligand concentration of 5 mM is indicative of gradual saturation of specific nucleotide-binding site. Observed increase in per cent NOE at ligand concentrations >5 mM may arise due to weak binding of ATPMg(II) at some adventitious site(s). Similar behaviour has been observed in case of rabbit muscle creatine kinase¹⁸ and yeast pyruvate kinase²⁰. From these data it is clear that for the determination of bound nucleotide conformation, measurements must be performed on a sample with a ligand concentration <5 mM.

Structure-dependent intramolecular NOE measurements

For the determination of conformation of adenosine moiety bound to BSA, measurements were made on a sample containing 4.0 mM ATP. Such sample composition maximizes the binding of ligand at the specific site and restricts interaction at low affinity non-specific sites.

Figure 3. TRNOESY spectrum of BSA.ATPMg(II) complex recorded at 500 MHz and 10°C. The sample contained 0.572 mM BSA; 4.0 mM ATP; 20 mM MgCl_2 in 20 mM sodium phosphate, pH 7.5. The sample volume was 600 μl . NOESY time domain data were collected with $256 \times t_1$ increments and 2 K points during each accumulation in t_2 . The mixing time of 160 ms and a relaxation delay of 2 s were used for the spectrum presented here. Two-dimensional Fourier transformation was performed along both the dimensions with a Gaussian apodization and zero-filling to obtain 1 K (F1) \times 2 K (F2) data set. The spectra were phased to pure absorption phase.

The mole fraction of bound ligand (P_b) was also within the range (~ 0.1 – 0.25) as suggested by Campbell and Sykes^{30,37} on the basis of theoretical considerations. The final sample composition chosen for NOE measurements was 0.572 mM BSA, 4.0 mM ATP and 20 mM MgCl_2 in 20 mM sodium phosphate, pH 7.5. Under such sample condition and for a $K_d = 2$ mM, P_b is ~ 0.1 . The experimentally measured NOE buildup curves are shown in Figure 5, where per cent NOE is plotted as a function of mixing time for different proton pairs. The points represent experimentally measured values, while the solid curves were theoretically simulated as described below.

NOE buildup curves (shown in Figure 5) were analysed to obtain the inter-proton distances. The data analysis was performed in a similar way as was done for creatine kinase and arginine kinase^{18,19}. Initially, the experimental NOEs were fitted with a second order polynomial in τ_m , including (0, 0) point as a part of data. Two distinct resonances are observed for $\text{H5}'$ and $\text{H5}''$ of free ATP. However, in the presence of Mg(II) , these two resonances overlap. In the analysis of data here, these two protons were treated as a single proton and observed cross peak intensities involving $\text{H5}'$ and $\text{H5}''$ were divided by a factor of two before fitting them with the polynomial. Using a calibration distance of 2.9 Å for $\text{H1}'\text{H2}'$ (refs 15, 20) in conjunction with equation (7) and the initial slopes obtained for different proton-pairs, a set of inter-proton distances were determined. NOE data for $\text{H1}'\text{H2}'$ with the calibration distance of 2.9 Å, also yields a value of $P_b\tau_c^b$ [see equations (4) and (6)]. These two parameters were separated by determining the P_b from the known dissociation constant. The set of initial slope distances, P_b and τ_c^b , obtained in this manner were

used as a starter for complete relaxation matrix calculations. The cross peak intensities were calculated for each spin pair as a function of mixing time (τ_m) according to equations (1), (3) and (4). To account for the contribution of free ATPMg(II) [see equation (3)], a τ_c^f of 0.3 ns (ref. 38) and inter-proton distances from an energy minimized structure were used. To obtain a better fit for the data at larger mixing times, a leakage term was added to account for the contributions arising from any external relaxation mechanism (see legend to Figure 5). The buildup curves computed theoretically on the basis of these parameters were then compared with the experimental data. At this stage any of the parameters, i.e. τ_c^b , r_{ij} and leakage terms could be adjusted to obtain the best fit for the experimental data. The bound correlation time, τ_c^b , chosen for the best fit of experimental data was 53 ns. The inter-proton distances determined from the analysis of TRNOE data are given in Table 1 along with the initial slope distances. The solid curves were computed using this set of distances along with other parameters mentioned in the legend of Figure 5. The distances derived from initial slope approximation and relaxation matrix calculations are plotted in Figure 6a. It is interesting to note that initial slope approximation underestimates the inter-proton distances which are > 3.5 Å. However, distance < 3.5 Å shows a good agreement between the two methods.

Bound nucleotide structure

The inter-proton distances derived from analysis of NOE data (see Table 1) were used as restraints in energy minimization calculations using Discover (V2.9.5) in conjunction with Insight II (V2.3.0). During minimization, experimentally obtained distances were used as target distances and a variation of $\pm 10\%$ was allowed. A symmetrical simple harmonic function with a force constant of $50 \text{ kcal mol}^{-1} \text{ \AA}^{-2}$ was used to restrain the inter-atomic distances within the range. Since there were no distances determined in the triphosphate chain region of ATP, calculations were performed only on adenosine molecule. Distance restraints were applied sequentially²¹, starting with H8 and all other protons. In the second step, the distances between $\text{H1}'$ and all other protons were used. In the third and the final step, all the distances were used. Each time, the energy minimization was performed using conjugate gradient method. The initial structure obtained in this manner fitted well with target distances. However, the energy of such structure was quite high compared to the energy of the free adenosine molecule. To further refine the initial structure, all the distances were used but the force constant was reduced to $25 \text{ kcal mol}^{-1} \text{ \AA}^{-2}$. This resulted in a structure with significantly lower energy with minor changes in inter-proton distances. Inter-proton distances between

Figure 4. Concentration dependence of per cent NOE for $\text{H1}'\text{H2}'$ proton pair in $\text{BSA}.\text{ATPMg(II)}$ complex for a mixing time of 120 ms. The ATP concentration was varied between 2 and 10 mM. The ATP:BSA ratio was kept at 10:1. The sample contained 2–10 mM ATP; 0.2–1 mM BSA; 20 mM MgCl_2 in 20 mM sodium phosphate, pH 7.5. The experimental points are represented by circles and the solid curves represent smooth interpolation through the experimental points.

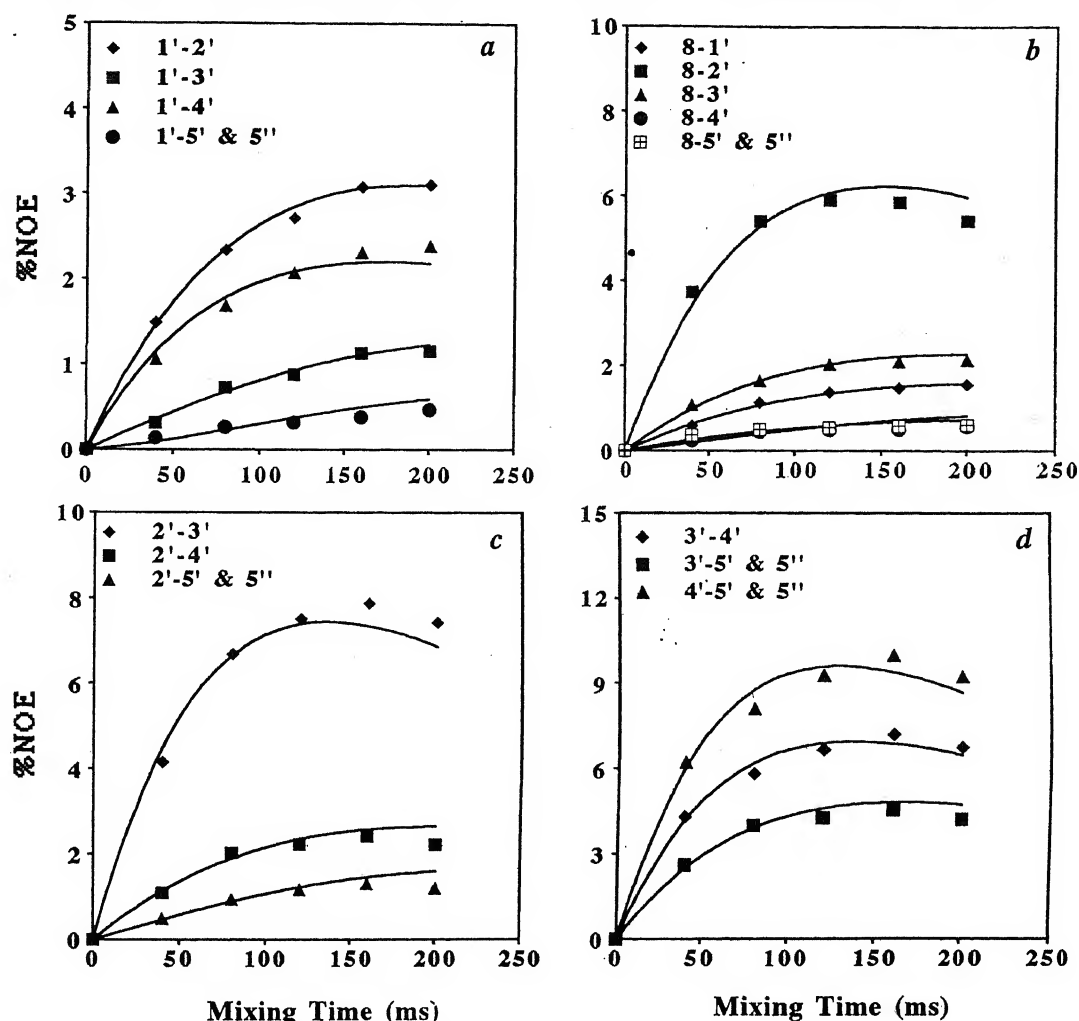

Figure 5. Per cent NOE for different pairs of ATP protons as a function of mixing time for BSA.ATPMg(II) complex. 600 μ l of the sample containing 0.572 mM BSA, 4.0 mM ATP, 20 mM MgCl_2 in 20 mM sodium phosphate, pH 7.5 was used. Spectral acquisition and processing parameters are described in 'Materials and methods'. The points represent experimentally measured cross peak volumes and the solid curves are the simulations based on the relaxation matrix distances given in Table 1. External relaxation rates for H8, H2, H1', H2', H3', H4', H5' and H5'' used in the fitting routine are 4.6, 2.0, 3.33, 3.33, 3.33, 2.86, 4.0 and 4.0 s^{-1} respectively. The rotational correlation time used for the bound ligand is 53 ns.

various pairs of protons in energy minimized structure are listed in Table 1. There are three violations in upper bound (between proton pairs H2'-H4', H2'-H5' and H3'-H5') and two in lower bound distances (between proton pairs H2'-H3' and H1'-H5') (see Figure 6b). Note that in these five violations, three involve H5' whose distance from other protons is difficult to determine accurately. The sum of upper bound violations (SUV) is 1.03 Å and sum of lower bound violations (SLV) is 0.14 Å. Thus the distances in energy minimized structure match reasonably well with those determined by NOEs. The structure of the nucleotide bound to BSA derived above is schematically represented in Figure 7. It has a glycosidic torsion angle $\chi = 48 \pm 5^\circ$, indicating an *anti* configuration of the adenine ring with respect to ribose. The values of various dihedral angles for the sugar ring are given in Table 2. In the notation of

Altona and Sundaralingam³⁹, the phase angle of pseudo-rotation is about 150° corresponding to an unsymmetrical C2'-endo-C1'-exo twist (2T_1) sugar pucker. The amplitude of the sugar pucker, τ is about 16° .

Discussion

Binding of ATP to BSA at a specific site was first reported by Bauer *et al.*⁶. Using appropriate spin labelled nucleotide analogues, these authors determined the binding constant for ATP to be in the range of 50–100 μM . Competitive displacement of bound spin probes by stearic acid suggested that the nucleotide binds at the site where the fatty acids interact. BSA is known to have about five fatty acid sites⁷, with a binding constant $\sim 10^6$ – 10^8 M^{-1} . Differential nature of these sites is evident

Table 1. Inter-proton distances determined for ATPMg(II) bound to bovine serum albumin. The uncertainty in distances is about ± 0.20 Å. Also note that distances of H5' and H5'' from any other proton are not determined separately as both protons resonate at the same frequency. Only in restrained energy minimization, this differentiation is made and separate distances are obtained

Proton pair	Inter-proton distances (Å)		
	Initial slope	Relaxation matrix	Energy minimized
H8-H1'	3.29	3.37	3.66
H8-H2'	2.49	2.50	2.36
H8-H3'	3.05	3.12	3.38
H8-H4'	3.86	4.35	4.11
H8-H5'	3.73	3.90	3.70
H8-H5''	3.73	3.90	4.12
H1'-H2'	2.90	2.90	2.93
H1'-H3'	3.59	3.80	4.00
H1'-H4'	3.06	3.00	3.23
H1'-H5'	4.29	5.50	4.86
H1'-H5''	4.29	5.50	5.19
H2'-H3'	2.42	2.37	2.08
H2'-H4'	2.96	3.05	3.58
H2'-H5'	3.36	3.66	4.39
H2'-H5''	3.36	3.66	4.05
H3'-H4'	2.46	2.40	2.67
H3'-H5'	2.66	2.65	3.36
H3'-H5''	2.66	2.65	2.35
H4'-H5'	2.32	2.25	2.49
H4'-H5''	2.32	2.25	2.51

from the fact that ethanol binds only at three of these sites. Ethanol binding fatty acid sites appear to be the same where 1-anilino-8-naphthalenesulfonate (1,8-ANS) also interacts^{24,40,41}. Further differences in binding determinants at these fatty acid sites are evident from the fact that ATP binds at only one of these sites. This region on the surface of BSA is likely to be amphipathic, i.e. aminoacyl residues present at this site are likely to be apolar and cationic. In the experiments presented here, we have determined the dissociation constant for binding of ATPMg(II) with BSA which is about an order of magnitude larger than that of free ATP (ref. 6). At pH > 7, free ATP has four negative charges whereas ATPMg(II) complex has only two. Adenosine 5'-monophosphate (AMP), which has two negative charges (resembles ATPMg(II) in this respect), also binds weakly with a dissociation constant in the millimolar range⁶. Binding affinity of a ligand to fatty acid binding region of BSA seems to be critically dependent on the number of negative charges on the ligand molecule. The observation of significant changes in the chemical shifts (see Figure 2) of the adenine and the ribose ring protons, indicate that these two rings along with triphosphate chain are involved in direct interaction with the BSA. Although binding of nucleotide to BSA has no known physiological function, interaction of all three regions of ATP with protein suggests that binding domain may resemble other ATP utilizing proteins. We examined the amino-acid sequence of BSA for the presence of a consensus sequence found in several ATP-binding pro-

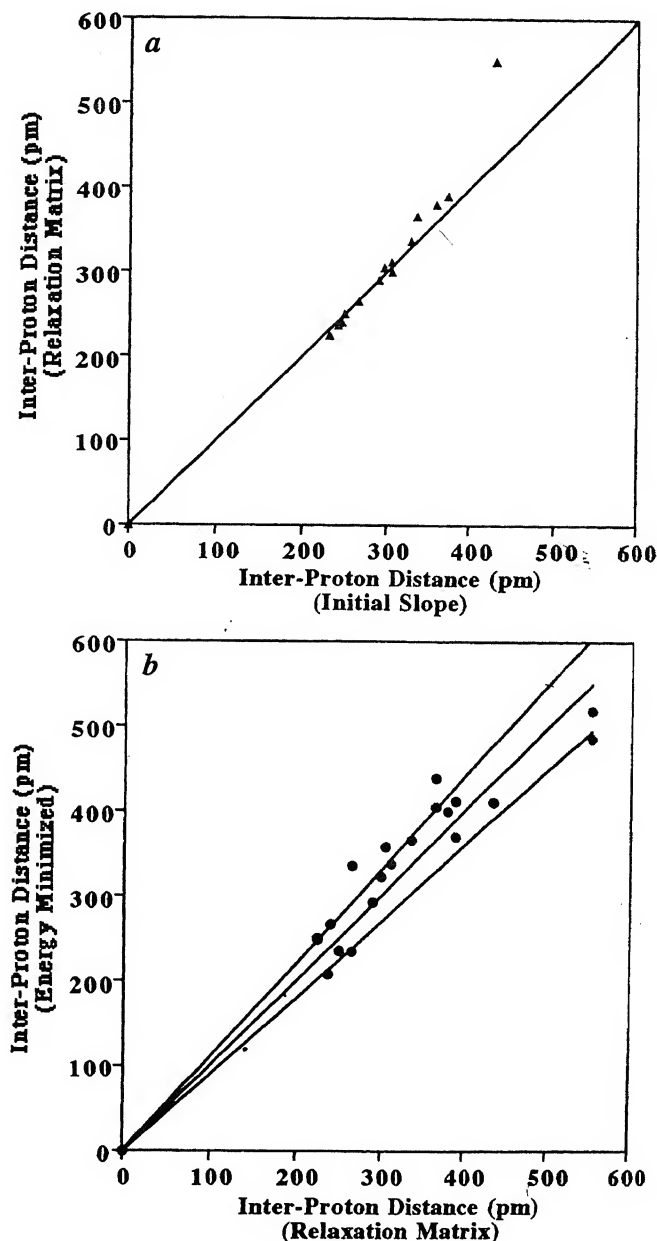

Figure 6. *a*, Comparison of inter-proton distances determined by initial slope approximation and complete relaxation matrix calculations. Fourteen different inter-proton distances determined for ATP in BSA.ATPMg(II) complex are presented. *b*, Comparison of relaxation matrix distances with the model distances derived from the final energy minimized structure of the bound nucleotide.

teins⁴². Aminoacyl residues 425-432, which have a sequence GVKGLSRS, is very similar to ATP-binding consensus sequence. This sequence is part of Domain-III which is known to have one high affinity fatty acid-binding site⁴³. It is quite likely that the specific ATP-binding site is located in Domain-III of the BSA.

In the titration experiment where chemical shifts of ATP protons were measured, we observe that at low

Figure 7. Schematic representation of ATPMg(II) structure bound at the specific site on the BSA (a) the glycosidic torsion angle (χ) and (b) the sign of various torsion angles defining the ribose conformation as well as the phase angle of pseudorotation (p) is mentioned.

Table 2. Different torsion angles and phase angle of pseudorotation (p) for the ribose when bound at the specific site on bovine serum albumin*

Torsion	Angle (degree)
χ (O4'-C1'-N9-C8)	48.0
ν_0 (C4'-O4'-C1'-C2')	-11.6
ν_1 (O4'-C1'-C2'-C3')	15.9
ν_2 (C1'-C2'-C3'-C4')	-13.5
ν_3 (C2'-C3'-C4'-O4')	6.6
ν_4 (C3'-C4'-O4'-C1')	3.3
γ (O5'-C5'-C4'-C3')	68.0
$p = \tan^{-1} \frac{(\nu_4 + \nu_1) - (\nu_3 + \nu_0)}{2\nu_2(\sin 36^\circ + \sin 72^\circ)}$	149.9**
$\tau = \frac{\nu_2}{\cos p}$	15.6

*The definition used for various torsion angles is the same as that described by Sanger⁴⁶.

**Since ν_2 is negative, 180° was added to the p value computed³⁹.

ligand concentration all proton resonances are shifted downfield to different extents. With increasing ligand concentration, the resonances shift progressively, approaching the chemical shift of free ligand at high ligand concentrations. Such behaviour is characteristic of a ligand resonance being in fast exchange²⁸. The largest chemical shift change observed for H2 proton of adenine ring allows us to determine the upper limit for the inverse of life time of BSA. ATPMg(II) complex, i.e. $k_{\text{off}} \gg 1200 \text{ s}^{-1}$. Decrease in binding constant with decreasing negative charges on triphosphoryl chain and observation of downfield shift of proton resonances of adenine and ribose ring suggest that all three regions of nucleotide are involved in binding interactions with the BSA.

The measurement of TRNOE between the H1'-H2' proton pair of ATPMg(II) as a function of ligand concentration (Figure 4) shows that at the higher concentration of ligand, large contributions to observed NOE may arise due to binding at adventitious site(s). In this respect BSA behaves similar to creatine kinase¹⁸ and pyruvate kinase²⁰. Experimental evaluation of the extent of non-specific binding is essential for selection of proper sample composition where site-specific TRNOE measurements could be made. Theoretical analysis of TRNOE data collected under appropriate sample conditions (to maximize specific site binding) implicitly involve the following assumptions. Firstly, the fast exchange conditions prevail, i.e. the inverse of the life time of the ligand in the macromolecular complex should be larger than the typical proton-proton cross relaxation rates. Secondly, it is assumed that all proton pairs have a single effective rotational correlation time (τ_c^b). It is, therefore quite instructive to estimate relaxation rates and compare with the 'off' rate for ATPMg(II) from the protein complex. The 'off' rate for bound ATPMg(II) obtained for BSA. ATPMg(II) complex from chemical shift measurements is $\gg 1200 \text{ s}^{-1}$. Bovine serum albumin, having a molecular weight of 66000 Daltons, may have a rotational correlation time as large as 60–70 ns. The cross relaxation rate between the two protons is given by $\gamma^4 \hbar^2 \tau_c / 10 r^6$ [see equation (4)]. For an inter-proton distance of 1.90 Å and $\tau_c = 70 \text{ ns}$, the cross-relaxation rate is 85 s^{-1} . The cross-relaxation rate computed here is much less than the 'off rate' (k_{off}) of the ligand from the protein complex. Thus, our analysis of TRNOE data using the formulation evolved for fast exchange condition is valid. Further, use of a single rotational correlation time, $\tau_c^b = 53 \text{ ns}$ for all the proton pairs is justified by the fact that the binding of nucleotide with protein involves all three regions of ATP. This will rule out any differential segmental motion for the ligand. The correlation time, $\tau_c^b = 53 \text{ ns}$ which gives the best fit for the experimental data, is in close agreement with the value computed on the basis of Stokes equation (~ 60 – 70 ns). In most of the ATP utilizing enzymes, τ_c^b obtained from the analysis of TRNOE data are much smaller (by a factor of 2–10) compared to Stokes equation estimates^{18–21,44,45} and this has been attributed to unaccounted spin diffusion in bound complexes.

The final structure determined for ATPMg(II) bound to BSA has a glycosidic torsion angle $\chi = 48 \pm 5^\circ$. This value is in general agreement with that obtained for several ATP-utilizing enzymes, viz. creatine kinase ($\chi = 51 \pm 5^\circ$)¹⁸, arginine kinase ($\chi = 50 \pm 5^\circ$)¹⁹, pyruvate kinase (active site $\chi = 44 \pm 5^\circ$, ancillary site $\chi = 46 \pm 5^\circ$)²⁰, phosphoribosyl pyrophosphate synthetase ($\chi = 50 \pm 5^\circ$)²¹, Mut T ($\chi = 53 \pm 9^\circ$)²³ (for AMPCPP). The sugar pucker, which is described by the phase angle of pseudorotation, $p = 149.9^\circ$, determined here is unsymmetrical C2'-endo

RESEARCH ARTICLE

C1'-exo twist (2T_1). The value of p differs greatly for different enzymes, e.g. 42.4° for pyruvate kinase (active site), 70.5° for creatine kinase, 114.9° for phosphoribosyl pyrophosphate synthetase, 130.8° for arginine kinase. Although the binding of ATPMg(II) to BSA has no known physiological function, it is interesting to note that the bound nucleotide has a conformation very similar to that at the active site(s) of several ATP-utilizing enzymes.

Digitized images of dimyristoyl phosphatidylcholine (DMPC) vesicular clusters, obtained from ordinary bright field microscopy were studied. The clusters followed certain scaling behaviour and could be characterized by the mass fractal dimension D and the porosity value P . Structural perturbations caused by the presence of the cytoskeletal protein, spectrin and hydrodynamic perturbations caused by dilution resulted in change in the above mentioned parameters. The results suggest that the collective behaviour of phospholipid vesicles can serve as an important tool to detect minor alterations in the microenvironment.

CLUSTER formation is a phenomenon which has drawn substantial interest from a wide variety of disciplines¹⁻⁷. Clusters can either be spanned (finite) or unspanned depending on whether the aggregate is bound or unbound within a given spatial domain. Contrary to the notion that the clustered assemblies are non-classifiable due to their random formation, it is now believed that minor changes in local interactions or initial conditions may lead to systematic changes in the geometric properties of clusters. Phospholipid vesicles, liposomes, have been widely used as a model system for the study of problems associated with the bilayer membranes, but clusters of spontaneously formed phospholipid vesicles are yet to be classified. We have studied such vesicle clusters under a brightfield microscope by image processing and subsequent analysis of such images to obtain the characteristic parameters for the clusters. In this report we examine the effect of dilution and structural perturbations caused by a cytoskeletal protein, spectrin, known to provide morphological integrity to the erythrocyte membranes.

Dried films of dimyristoyl phosphatidylcholine (DMPC) (Sigma) were hydrated in a buffer containing 5 mM phosphate, 20 mM KCl, 1 mM EDTA, 0.2 mM DTT, pH 8.0, with and without spectrin (200 µg/ml) to form multilamellar DMPC (4 mM) vesicles. White ghosts from goat blood were prepared by hypotonic lysis in 5 mM phosphate, 1 mM EDTA containing 20 µg/ml of PMSF at pH 8.0, following the procedure of Dodge and co-workers⁸. Spectrin was removed from the ghosts in a buffer containing 0.2 mM sodium phosphate, 0.1 mM EDTA, 0.2 mM DTT, 20 µg/ml of PMSF, pH 8.0

at 37°C. Spectrin dimers were purified after 30% ammonium sulphate precipitation by following published protocols⁹.

The DMPC vesicles, after an hour of incubation at room temperature, were spread on a glass slide, and were visualized through the bright field of an ordinary microscope (Model Diastar, Reichert Scientific Instrument, USA). At least four different fields of view were visually scanned to test the gross uniformity of the resultant clusters. The computer-grabbed images were imported into Windows environment (Microsoft Corporation, USA) using MATLAB under Windows (MathWorks Inc., USA). Figures 1 *a* and *b* show the digitized grey images of the DMPC vesicles in absence and presence of spectrin.

Image processing was performed by Image Processing Toolbox procured from MathWorks. In most cases, however, routines specific for the problem, were developed. For processing the indexed images, the first step was thresholding. The optimal choice for threshold grey value was made following the reported method with minor modifications¹⁰⁻¹², where the histogram of grey value of each pixel was taken with 50 number of bins. Then, the overall extraction was carried out with the grey value corresponding to the bin which is 4th in position regarding frequency.

Once the thresholded image is obtained, one may obtain two classes of information. Firstly, one might ignore the porosity space and observe the cluster contour. Secondly, one might be interested in following up how the image pattern changes by rescaling (i.e. by sampling the image points in frame, with an altered grid distribution). Thus the original grey level image in Figure 1 *a* is subjected to thresholding in Figure 2 *a*, which contains the binary information about the porous region as well as the cluster contour. Figure 2 *b* represents the clusters without any indication to the porous region. Rescaling has been illustrated in Figure 2 *c*, which shows how scaling alters the thresholded image (Figure 2 *a*).

To measure the cluster area including pores (A) from the binary image (i.e. to generate Figure 2 *b* from Figure 2 *a*, the image was first fixed in a rectangular frame). To include the porous region in the calculation of area, the following overlay method was followed. Eight separate images were generated by unit pixel translation parallel to positive and negative directions of abscissa keeping the ordinate fixed, parallel to positive and negative directions of ordinate keeping the abscissa fixed and parallel to the four diagonal of the image frame respectively. The translated image points were layered on top of one another and the union of all such points was called the image O' (data for Figure 2 *b*). To obtain rescaled image (Figure 2 *c*), the image co-ordinates were subjected to suitable scaling transformations.

To get the mass fractal dimensions of the clusters we

*For correspondence

Figure 1 *a, b*. Clusters of DMPC vesicles in (*a*) absence and (*b*) presence of spectrin.

Figure 2 *a-c*. Different stages of processed images (*a*) binary image conversion after thresholding, (*b*) image showing the area within the total cluster contour and (*c*) rescaled image with length scale elongated two-fold (10 pixels = 13.9 μm).

resized all the input thresholded binary images. For this, the input image was scanned blockwise (size of each block was assumed as $a \times a$) each time checking the total grey value, G of each block with the following rule:

if,

$$G(i, j) > 0 \text{ then } R(i, j) = 1; \text{ else } R(i, j) = 0,$$

endif,

where the scale length was represented by a , the size of the input image matrix was m and the size of the output image, R (Figure 2 *c*) was, $L = m/a$. The cluster mass, M (number of white pixels, or occupied sites) of the resized images was measured at different lattice sizes, L ($L = 4, 6, 8, 10, 12, 16, 20, 24, 28$ and 32

pixels). The exponent, D , could be obtained from the equation given by¹³:

$$M = L^D, \quad (1)$$

where the slope of the linear fit of $\ln(M)$ plotted against $\ln(L)$ gives the measure of D , shown in Figure 3.

To evaluate the porosity of the clusters from their two-dimensional view, the expression of the porosity in the three-dimensional space^{14,15} might be modified as

$$P = 1 - A_i/A, \quad (2)$$

where A is the overall cluster area and A_i is the area excluding the pore space.

DMPC films upon hydration with the aqueous buffer

formed large multilamellar vesicles, which upon incubation at 25°C formed stable clusters. When spread on the microscopic slides, spanned clusters were observed without any relative movement between the cluster components. The clustered patterns remained visually similar even when the microscopic slide was physically shifted in the x - y plane. We have obtained a good linear fit in the plots of $\ln(L)$ and $\ln(M)$ (Figure 3), both in absence and presence of spectrin. In the initial stock solution the D value was notably higher in presence of spectrin than that in the absence. After two-fold dilution, a decrease in D was observed in presence of spectrin (200 $\mu\text{g/ml}$), while the D remained unchanged in its absence (Table 1). However, a gradual increase in D , at 2-fold dilution, was evident with the increasing concentrations of spectrin (Figure 3 *b*). Data for evaluation of porosity P , were collected from the threshold-image using eq. (2). For stock solutions we found the mean value of P for clusters of DMPC vesicles to be much lower in the absence of spectrin than that in the presence of spectrin. After two-fold dilution the mean value of P significantly increased for the clusters without spectrin. But on contrary, after 2-fold dilution P remained almost unchanged in the presence of spectrin.

As we see from Table 1, the mean mass fractal dimension, D for the stock DMPC vesicular suspension was significantly lowered (≈ 1.662) in the absence of spectrin than in presence of spectrin (≈ 2.0). The magnitude of D implied that for the DMPC vesicular clusters including the cytoskeletal protein, spectrin, the cluster formation is above the limit of percolation threshold. The cluster formation is below the limit of percolation

threshold when spectrin was not included in the phospholipid vesicles¹³. A gradual increase of D was observed with the increase in spectrin concentration (100–400 $\mu\text{g/ml}$), implying retention of stability in presence of spectrin (Figure 3). Furthermore, for stable clusters one would expect conservation of the geometric properties even in presence of hydrodynamic perturbation. In presence of spectrin the porosity coefficient P , remains relatively insensitive to dilution. This provides an additional support to the earlier conjecture.

Spectrin is the cytoskeletal protein known to provide morphological integrity to the erythrocyte membranes¹⁶. Earlier studies have shown altered vesicular geometry in presence of structural proteins^{17,18}. Most of such studies were confined to the analysis of individual liposomes. Spectrin is known for its membrane adhesive properties and results presented here do support that spectrin confers more stability to the overall cluster characteristics formed by multilamellar DMPC vesicles. The simple methodology presented here might be useful in characterizing clusters from their geometry, despite ambiguity and variety in the microscopic appearances

Table 1. Mean and standard deviation of fractal index and porosity in absence (–) and presence (+) of spectrin

Fractal index (D)		Porosity (P)	
– Spectrin	+ Spectrin	– Spectrin	+ Spectrin
1.66 ± 0.02 (1.69 ± 0.01)	2.02 ± 0.03 (1.75 ± 0.01)	0.16 ± 0.02 (0.45 ± 0.04)	0.44 ± 0.01 (0.39 ± 0.005)

Values in parenthesis correspond to the same after two-fold dilution.

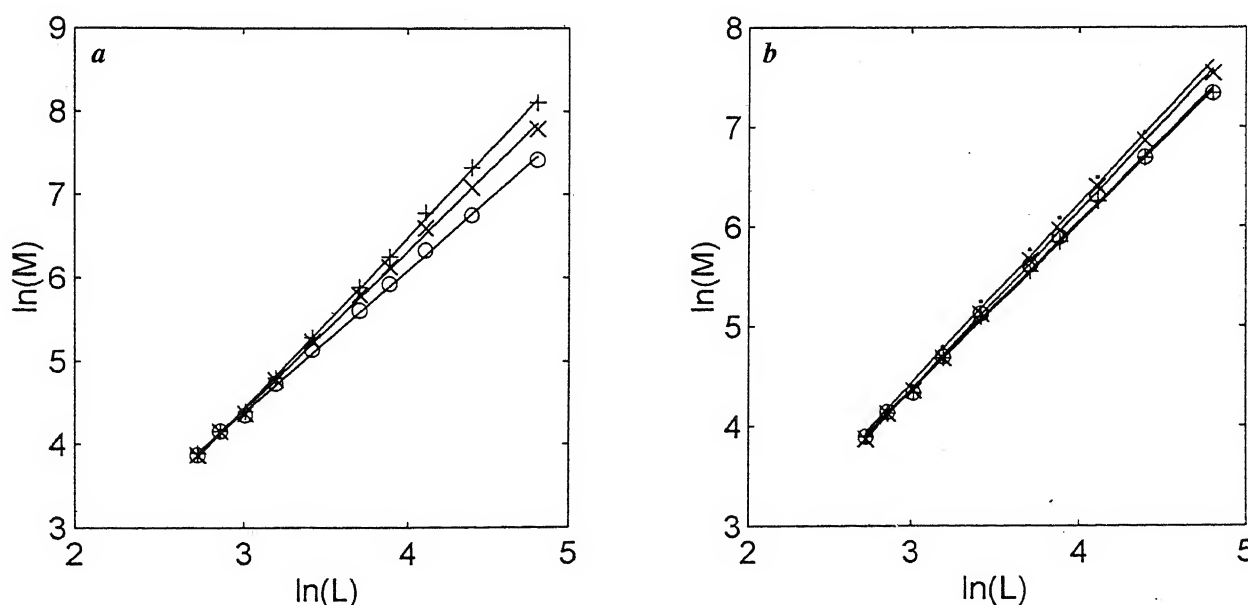

Figure 3 a, b. Plot of $\ln(M)$ against $\ln(L)$. Stock vesicular suspension and two-fold dilution of the same are represented by *a* and *b* respectively. The symbols 'O', '+', 'x' and '*' represent spectrin concentration of 0, 100, 200 and 400 μg per ml respectively.

of their individual vesicular forms. The property of clusters responding to the minute perturbing changes in the individual constituting members, might be, in our view, an important tool in the study of cellular or vesicular assembly processes.

Received 20 July 1996; revised accepted 25 October 1996

The plant Banjauri (*Vicoa indica*) exhibits antifertility activity in adult female bonnet monkeys (*Macaca radiata*)

A. J. Rao*, N. Ravindranath[†] and N. R. Moudgal

Primate Research Laboratory, Center for Reproductive Biology and Molecular Endocrinology, Indian Institute of Science, Bangalore 560 012, India

[†]Department of Anatomy and Cell Biology, George Town University Medical Center, 3900 Reservoir Road, NW, Washington DC 2007, USA

The antifertility activity of the plant *Vicoa indica* was tested in proven fertile bonnet monkeys. The dry powder of the whole plant was fed to the cycling monkeys on day 1 to 14 of menstrual cycle or day 9 to 14 of cycle or on day 2 to 5 after delivery and the fertility was evaluated in the following cycle in cycle fed monkey or after weaning the young one in the post-partum fed monkeys. Results indicated that while feeding in the post-partum monkeys did not confer any protection against pregnancy feeding during day 1 to 14 of cycle, protected from pregnancy. The monkeys did not become pregnant even after exposure to the proven fertile male monkeys for 13 ovulatory cycles while all the vehicle fed monkeys became pregnant within 3 cycles.

BANJAURI is the colloquial name for the plant *Vicoa indica* which belongs to the family Compositae. It is a

small plant of about 1-2 feet height with slender stem, long leaves and small yellow flowers. The plant grows wild in the months of July/August and fully mature plants with flowers are seen during September/October. It is reported¹ that the Adivasi tribes in Bihar use Banjauri as a contraceptive. According to the practice followed by Adivasis, the freshly collected plant is sun-dried and the whole plant equivalent is powdered along with seven pepper seeds and consumed each day as a suspension in water by woman on the second to fifth day after delivery of the child or from day 1 to 14 of three consecutive menstrual cycles. Such treatment reportedly induces permanent sterility. In view of the nonavailability of scientifically documented clinical study on the use of Banjauri, we have attempted to verify the activity profile of this plant product by determining the effect of feeding dried Banjauri powder both during post-partum period and early phase of the menstrual cycle on fertility of proven fertile adult female bonnet monkeys.

The procedures adopted for care and maintenance of bonnet monkeys have been reported in detail earlier². The serum levels of estradiol-17 β , progesterone and chorionic gonadotropin were determined according to methods described earlier³.

Dried plant material was powdered and passed through a metal sieve (500 μ mesh) to remove coarse fibrous material. The finely powdered material was mixed with groundnut seeds and brown sugar in a ratio of (1:4:8) and thoroughly ground in a mortar and the resulting paste was fed to the monkeys. Care was taken

*For correspondence

to see that the entire material was consumed by the animal and those animals where uncertainty existed regarding intake were discarded from the study. In a separate study, a suspension of Banjauri plant powder in water was deposited in the stomach of female monkeys using a Riles tube.

The first set of experiments were carried out to determine whether the extract is toxic to the monkeys. To a set of monkeys, a total dose of 26 g/monkey (2 g of powder/day) was fed over a period of 13 days. A control set of 3 monkeys received only brown sugar and groundnut powder. The initiation of the feeding of the plant powder to each monkey was done on different days of menstrual cycle as the study was primarily aimed to examine whether the material has any toxic effects on the monkeys. Blood samples were collected before and after the feeding of the powder and analysed for haematological parameters. After feeding the animals were sacrificed and brain, liver, kidney, gonads, muscle and other tissues were collected for histological examination. The blood samples were subjected to haematological, biochemical and endocrinological studies.

Two regimens were employed to ascertain the anti-fertility effect of Banjauri. The first consisted of feeding Banjauri on the 2nd, 3rd, 4th and 5th day following delivery of the young (Group I). In the second, Banjauri

was fed daily from day 1 to 14 of a menstrual cycle (Group II). The post-partum monkey study consisted of two subgroups. While group IA received a total dose of 6 g (1.5 g/day) for 4 days starting from 2nd to 5th day post-partum group IB monkeys were fed a total dose of 60 g (5 g/day given in two doses, one in the morning and one in the evening) over a period of 12 days from day 2 to 14 after delivery. The cycling monkey study was again made up of 2 subgroups. While monkeys in group IIA were given 1.0 g/day for 14 days from day one of the menstrual cycle, those in group IIB were given 2.0 g/day for 14 days from day one of menstrual cycle. A third group (IIC) was given a total dose of 50 g (5 g/dose) from day 1 to day 10 of menstrual cycle.

In the case of monkeys which were fed Banjauri during post-partum period, their fertility was tested following weaning of babies (done six months after delivery) and return to cyclicity (approximately 9–12 months after parturition). In the case of monkeys fed Banjauri during menstrual cycle, the animals were tested for fertility from second cycle onwards.

Female monkeys which had received the drug were placed with proven fertile breeder males (1 : 1) between days 9 and 14 of a menstrual cycle. Those monkeys which did not become pregnant during the first cycle

RESEARCH COMMUNICATIONS

exposure were exposed to fertile males during subsequent cycles.

The ovulatory nature of the cycle and establishment of pregnancy were determined by assaying serum for estradiol 17- β and progesterone and CG by methods standardized earlier in this laboratory³.

Feeding trials revealed that the groundnut powder and brown sugar are very good additives as they completely masked the leafy odour. However, attempts to feed beyond 5 g/day were not successful as the monkeys wasted considerable quantities of the material fed.

Tables 1 and 2 show that there are no gross changes in the haematological, biochemical and histological parameters and as such the plant powder at the dose tried was considered to be non-toxic. Though a detailed study was not carried out even in the monkeys fed 5 g

of Banjauri per day for 10 days no deleterious effects were observed.

Table 3 shows that feeding of 50 g of Banjauri had no significant effect on the serum estradiol on day 9 and 11 and progesterone on day 18, suggesting that Banjauri had no gross effect on the menstrual cyclicity. However, it should be noted that decrease in serum progesterone levels (less than 2 ng/ml Banjauri fed in monkeys compared to >2 ng/ml in control monkeys) did not result in any alteration in the length of the menstrual cycle.

Table 4 also shows that all the control monkeys fed vehicle become pregnant within 2.2 cycle exposures to proven fertile male monkeys, an observation which is in agreement with the earlier results⁴.

Table 5 shows that the monkeys fed either 6 g or

Table 3. Serum estradiol from day 1 to 10 of menstrual cycle and progesterone levels in vehicle fed ($n=3$) and *Vicoa indica* (50 g/day $n=4$) fed monkeys

Group	Duration of cycle (days)	Serum estradiol (pg/ml) on		Serum progesterone (ng/ml)
		Day 9	Day 11	Day 18
Control	29 \pm 3	136 \pm 17	236 \pm 21	1.52 \pm 0.2
<i>Vicoa indica</i>	27 \pm 5	242 \pm 50	178 \pm 18	1.60 \pm 0.5

Mean \pm SE.

Table 4. Effect of feeding dried Banjauri plant powder during post parturition period on fertility in the female bonnet monkey

Group	n	Total dose (g)	No. of ovulatory cycles/ total no. of cycles exposed	Mean no. of cycles needed to become pregnant	Parameter
Control	5	6 (vehicle)*	11/16	2.2	All delivered live young
IA	6	6 (Banjauri)	18/30	3.0	All delivered live young
IB	5	50 (Banjauri)	6/9	1.2	All delivered live young

*A mixture of groundnut powder and brown sugar was used as vehicle. The total dose was given orally in 4 equal portion on days 2, 3, 4 and 5 of lactation.

Each animal was exposed to a proven fertile male during day 9–14 of each cycle. The cycle was considered ovulatory if serum estrogen on day 8/9 was at least 200 pg/ml (range 200–960 pg/ml) and serum progesterone on day 18/19 was at least 2 ng/ml (range 2–9.6 ng/ml).

Table 5. Effect of feeding dried Banjauri plant powder during menstrual cycle in proven fertile female bonnet monkeys on their ability to conceive during subsequent exposure to fertile males

Group	n	Dose (g/day)*	No. of ovulatory cycles/ total no. of cycles exposed	Mean no. of cycles needed to become pregnant	Parameter
IIA	4	1.0	14/16	3.5	All delivered live young
IIB	6	2.0	82/126	–	None became pregnant even after 13.7 ovulatory cycle exposures
IIC	3	5.0	17/	–	One became pregnant after 6 cycles One became pregnant after 10 cycles One showed erratic cycles

Each animal was exposed to a proven fertile male during day 9–14 of each cycle. The cycle was considered ovulatory if serum estrogen on day 8/9 was at least 200 pg/ml (range 200–960 pg/ml) and serum progesterone on day 18/19 was at least 2 ng/ml (range 2–9.6 ng/ml).

*Mean cycle length of 28 g Banjauri fed monkeys computed from 54 cycles was 29.2 \pm 4.4 days.

*Whereas groups IIA and IIB received treatment from days 1 to 14 of the first cycle, group IIC received treatment for days 1–10 of the first cycle.

50 g of Banjauri during post-partum period were not protected against pregnancy and all the animals became pregnant within 2 to 3 cycle exposures to proven fertile males.

To test the efficacy of Banjauri to block fertility of regularly cycling monkeys totally three different regimens were employed. Monkeys which were fed 1 g/day over 14 days ($n=4$) became pregnant within 3 exposures to males. However, monkeys which were fed 2 g/day for 14 days remained non-pregnant even after 22 (mean) exposures to proven fertile male monkeys (Table 5). The number of ovulatory cycle exposures varied from a minimum of 14 to a maximum of 25. Out of these cycles 65% were ovulatory as judged by serum estradiol levels on day 9/10 and progesterone levels on day 18 of cycle. In the group which received 5 g/day over a period of 10 days one became pregnant after six cycles, one conceived after 10 cycles while one exhibited very erratic cycles and as such breeding studies with this were discontinued. It was also noticed that the animals which were fed 2 g Banjauri/day did not cycle properly during later part of the study (i.e. 18 months after termination of feeding) as judged by serum steroid (E_2 and P_2) hormone levels. A comparison of the number of exposures needed for pregnancy in our colony revealed that while in the control monkeys an average of 2.2 cycle exposure is needed to become pregnant, in the monkeys fed Banjauri during the menstrual cycle the animals remained non-pregnant even after 20–22 cycle exposures.

Indian folklore has several claims of medicinal plants having contraceptive efficacy. The majority of the claims, however, have not been subjected to strict scientific verification. The present study reveals that the dried powder of *Vicoa indica* administered as suggested by the folklore, i.e. in post-partum monkeys is not effective in conferring protection against pregnancy during subsequent exposures to proven fertile males. The dose administered was based on that claimed to be effective in the human. However, the animals which were fed a total dose of 28 g during days 1–14 of menstrual cycle, remained non-pregnant even after 150 ovulatory cycle exposures. It should be emphasized that the colony data suggest that an average of 3 ovulatory cycle exposure is adequate for pregnancy establishment and the fertility index of the female colony is fairly high. Also of the total number of cycles exposed, only ovulatory cycle was considered and even this is 5 times more than the number required for the control and in spite of so many exposures the animals have remained non-pregnant. A similar effect was observed in animals fed Banjauri by intragastric deposition. In view of the fact that the administration of plant powder is effective only when fed during the menstrual cycle, it is possible that the

active principle in the plant induces some irreversible changes in the reproductive tract (fallopian tube or uterus) resulting in infertility. Although this is only a preliminary study providing evidence only for the efficacy of the plant and not identifying the active principle, we feel that this observation needs attention in view of the possible potential as safe oral contraceptive. It is pertinent to note here that in a recent clinical trial conducted with Banjauri on 362 lady volunteers who were given 50 g of powder in a single dose on 2nd day of abortion along with water and eleven black pepper seeds only 14 cases of drug failure were reported⁵. It is currently unclear if the active principle of this plant product is affecting implantation or early embryonic development in the fallopian tube itself. Three compounds (sesquiterpene lactones) designated as Vicolide A, Vicolide B and Vicolide C have been isolated and characterized from the plant *Vicoa indica*. Of these, vicolide B was found to have antifertility activity in Wistar rats when administered at a dose of 100 mg/kg body weight⁶ and this was ascribed to the compound having antiestrogenic activity⁷. The possibility of these compounds bringing about occlusion of the fallopian tube has also to be considered. In this connection, the ability of quincarine to bring about occlusion of the fallopian tube may be of significance⁷. Considering that this plant extract provides extended protection against contraception following ingestion for one cycle only, it is felt that further controlled studies with the crude plant extract and few of the vicolide derivatives in non-human as well as human primates are warranted.

Plantlet regeneration from leaf explants of oil palm seedlings

Anitha Karun and K. K. Sajini

Central Plantation Crops Research Institute, Kasaragod 671 124, India

Plantlet development was achieved from leaf explants of 18-month-old *dura* and 6-month-old *tenera* oil palm seedlings. Callus induction was noticed after 100–120 days in *dura* and 150–180 days in *tenera* on culturing in half strength Murashige–Skoog basal medium supplemented with 25 mg l⁻¹ 2,4-dichlorophenoxyacetic acid. Seven per cent of the cultured explants in *dura* and 10% in *tenera* produced embryogenic calli. These were transferred to regeneration medium containing 1 mg l⁻¹ zeatin riboside. Plantlet development from calli was achieved through both somatic embryogenesis and organogenesis. Histological studies on developmental stages were also reported.

CLONAL propagation of oil palm has commercial importance¹⁻³. Being a recalcitrant tree crop, the success of micropropagation of oil palm is chiefly related with the choice of explants; tissues from juvenile trees are found to be more responsive⁴. The tender leaf tissues of oil palm seedlings offer good source of explants for reasons of easy availability and sampling. Micropropagation will enable large-scale production of *tenera** hybrids from the performance tested *Dura* × *Pisifera* crosses. Here we describe the various stages of plantlet regeneration by using tender leaf explants of 18-month-old *dura* and 6-month-old *tenera* seedlings.

The sprouts of *dura* and *tenera* were collected from the Central Plantation Crops Research Institute, Regional Centre, Palode and maintained as pot cultures at CPCRI, Kasaragod. The *dura* seedling sampled for the present study is from the cross between 3D × 266D and the *tenera* hybrid from 333D × 609P. The seedlings were sampled destructively by removing the outermost leaves and retaining a few interior leaves with the middle column and surface sterilized by alcohol flaming inside a laminar flow. Subsequently, the outer leaf whorls were removed and only the central portion with meristematic region was used for culturing. Leaf lamina and leaf base were cut into small pieces (0.5 to 1 cm). A total of 60 leaf explants of *dura* and 30 leaf explants of *tenera* were initially inoculated into callus induction medium.

The details of the culture media are given in Table 1. The cultures in the callus induction medium were first incubated in controlled conditions (temp. 27 ± 2°C; rela-

tive humidity 55–60%) in dark till callus induction was noticed. Subsequently, the cultures were maintained in illuminated conditions with 16 h photoperiod (2500 lux) for further differentiation. Subculturing was done at monthly intervals.

The specimens selected for histological studies included developmental stages of somatic embryos and meristemoids. These were fixed in Carnoy's B fixative (60% absolute alcohol; 30% chloroform; 10% acetic acid) for 24 h and were dehydrated in alcohol–butanol series before embedding in paraffin wax. Serial sections of 10 µm were taken using a microtome. After deparaffinization, they were stained with 0.1% toluidine blue (TB), periodic acid Schiff's reagent (PAS) and mercuric bromophenol blue (MBB) respectively for the detection of total nucleic acids, total insoluble polysaccharides and total proteins^{5,6}.

Nodular calli were produced from leaf veins after 100–120 days of inoculation in *dura* (Figure 1) (4/60 cultures), while it took 150–180 days in *tenera* (3/30 cultures). No direct embryogenesis was observed. The actively dividing cells in culture medium are dominated by callus-forming habits⁷ and so was the case with the leaf explants excised from the basal parts. On transfer to the somatic embryogenesis/organogenesis medium the primary calli regenerated into somatic embryos and fast growing calli (Figures 2 and 3). The frequency of various developmental stages is shown in Table 2. Compared to *dura*, the regeneration process was slow in *tenera*. In this case the supplementation of zeatin riboside to the medium was delayed for 50–60 days and might have slowed down the regeneration process. The quantity of calli and the regeneration capacity were found to reduce on increasing the interval between subculturing (45–50 days). Somatic embryos developed into complete plantlets in the regeneration medium (Figures 4 and 5) whereas, fast-growing calli directly gave rise to a large number of meristemoids (Figures 6 and 7). Shoot development from meristemoids took 90 to 100 days. It may be seen that a larger share of plantlets was derived through organogenesis than somatic embryogenesis. However, plantlet regeneration through somatic embryogenesis with a minimum callus phase was also reported in oil palm⁸. Shoots with 3–4 leaves and having a height of 10–12 cm were subsequently transferred to rhizogenesis medium. Sufficient roots were produced (Figure 8) within 3–4 weeks. In some cases, filter paper bridges were provided to prevent the complete immersion of shoot for a long time. Plantlets with balanced roots and shoot were obtained within 60–80 days of culturing in rhizogenesis medium (Figures 9 and 10) and were transferred to pots.

At the time of transferring to pots, the plantlets were treated with Bavistin (1%) and thereafter with IBA solution (1000 ppm) for an hour. The potting mixture

*Based on the fruit structure, oil palm is classified as *Dura* (thick shell; less mesocarp), *Pisifera* (shell less; embryos rarely formed) and the commercially cultivated *Tenera*, the D × P hybrid (thin shell; more mesocarp (60–95%), with high oil content).

used was sterilized with autoclave soil, sand and coir dust in equal portions. Initially, high humidity was provided to the plantlets by covering them with polythene bag; humidity was then gradually reduced by providing perforation to the bags and later by removing the bags during night. After 4 weeks, the bags were removed completely. The *ex vitro* establishment of plantlets was observed to be satisfactory (Figure 11). After 18 months from the start of the experiments, there were 175 plantlets established in pots. Comparable results were observed on repeating the experiments in three *dura* seedlings and two *tenera* seedlings.

Histological studies were done in *dura* palm cultures and the following observations were made. The primary calli were nodular and originated from the perivascular region of the vein, similar to the type obtained by

Schwendiman *et al.*⁹ in oil palm. These adventitious nodules could be easily separated from each other at the fragmentation lines (Figure 13). This physical isolation of calli from the explants is a prerequisite for somatic embryogenesis¹⁰. The fragmentation lines that demarcate the meristematic locus were also reported in the case of date palm¹¹ and oil palm¹². The nodular structures derived out of pale yellow coloured calli that tend to differentiate were found to be rich in nucleic acids (Figure 13). Cell differentiation was found to be very rapid in these fast-growing calli. In this stage, a combination of increased divisions and decreased differentiation confers a meristematic state on the cell nodules, which is an essential prerequisite for embryogenic competence of its cells¹³. It was observed in the present study that the origin of somatic embryos/mer-

istemoids was from a group of cells (multicellular) (Figure 13). The proembryogenic nodules were found to be present towards the periphery of the calli, the rest of the cells in the calli probably acting as nurse tissue to the emerging embryoids. These observations are in confirmation with those made by Schwendiman *et al.*⁹.

Continued meristematic activity was observed in the calli which led to the formation of a central zone of the embryonic shoot apex (Figure 14). Subsequently, the apex became well defined as a rounded dome (Figures 15–17). After 6 weeks of culture in the regeneration medium, green-coloured structures were observed on the surface of the calli. All these structures were highly vascularized and they play the role normally attributed to the haustorium by taking up nutrients from the culture medium. Cross sections of these structures showed a large number (10–25) of meristemoids and shoot primordia (Figure 12). A representative series of developmental stages is shown in Figures 14–20.

Differentiating conductive and resistive inhomogeneities: A new approach in groundwater exploration

P. N. Ballukraya

Department of Applied Geology, University of Madras, Guindy Campus, Madras 600 025, India

Lateral inhomogeneities, such as dykes or shear zones give rise to false low-resistivity layers in vertical electrical sounding curves which are likely to be misinterpreted as a water-bearing zone at depth. In groundwater exploration it is necessary that such anomalies be identified, i.e. a near-horizontal discontinuity, a conductive (probably water-bearing) lateral inhomogeneity or a resistive (e.g. a dyke) vertical feature. Lateral effects can be distinguished from those due to depth effects by offset soundings or crossed azimuth soundings, while conductive lateral inhomogeneities can be differentiated from resistive ones by a modified azimuthal sounding technique. Under favourable geoelectric conditions it may be possible to determine the direction and amount of dip of the vertical feature as well so that well sites could be located at a suitable distance in the down dip direction of the feature.

In the predominantly crystalline rock terrains of south India, groundwater occurs in two distinct zones, namely the near-surface weathered and decomposed rock material (regolith) and the joints and fractures that may extend to a few hundred metres depth in the underlying bed rock. Shear zones are also often found to contain substantial amounts of groundwater, as such zones are generally highly fractured and jointed, a condition conducive for storage and movement of groundwater. Over-exploitation of groundwater in several parts of southern India has resulted in the drying up of the weathered rock horizon, restricting the availability of groundwater to the fractured rock zones, which extend to relatively deeper levels. The success of a borewell under these conditions depends on the presence of such deep water-bearing zones, and therefore, it is essential that they be identified to successfully locate sites for constructing water wells.

Availability of groundwater in these fractures, joints, shear zones, etc. is facilitated by weathering of the parent rock along them, increasing their porosity, and hence, water holding and transmitting capacity. It must be emphasized here that below a certain depth the weathering of the parent rock is confined mainly to the joint planes of the fracture and shear zones, leaving the bulk of the rock body un-altered and relatively fresh. The weathering renders such zones electrically more conductive in comparison to the country rock, and hence, at first glance, it may appear to be an easy target for

exploration through geo-electric techniques. However, these weak zones in the country rock, often having narrow widths and with dips ranging from vertical to near-horizontal, are likely to be missed during investigations. But, in view of the importance of identifying them for a successful groundwater development programme, detailed investigations were carried out to develop a suitable exploration technique. From these studies, a field methodology has been evolved to identify vertical and near-vertical features, differentiate them as geo-electrically conductive or resistive and then approximately determine the direction and dip amount of these lateral inhomogeneities.

The vertical and near-vertical joint/fracture zones, narrow shear zones, dykes and veins can essentially be considered as lateral inhomogeneities in the country rock. Their presence in an area may be recognized by the resistivity anomalies they generate, provided that these inhomogeneities are sufficiently wide, and also that adequate resistivity contrast exists between them and the country rock. Resistivity profiling using alpha-, beta- and gamma Wenner arrays^{1,2} or vertical electrical soundings (VES) such as Barker's³ offset Wenner soundings and crossed azimuth soundings⁴ are helpful in identifying lateral inhomogeneities. However, these techniques are used only when one is specifically looking for the presence of lateral inhomogeneities and rarely

otherwise. In groundwater exploration using resistivity methods, the normal practice is to carry out a few vertical soundings in the area of interest and select the best out of them for constructing wells. The problem is therefore to identify the presence of vertical features, if and when present, from an analysis of these VES curves without resorting to the above additional techniques. It is known that a lateral inhomogeneity, be it resistive or conductive, gives rise to a false low-resistivity geo-electric layer in the VES curve, when one of the current electrodes is in contact with it^{4,5}. A low-resistivity layer in a VES curve may also be caused by a relatively more conductive lithological unit at depth. The problem is shown in Figure 1, wherein three instances of diverse geological conditions giving rise to essentially identical VES curves are shown. This underlines the need for a technique to differentiate between the causes of these anomalies.

The objective of identifying a lateral inhomogeneity is achieved by the so-called offset sounding method described by Ballukraya *et al.*⁴, wherein a series of closely spaced soundings are carried out along a common electrode spread direction. Schlumberger electrode array has been found to be preferable for this purpose as it minimizes errors in the measured values that may be introduced by the shifting of potential electrodes for each and every measurement, as with Wenner electrode

Figure 1. Shape of the VES curves that may be obtained over three different geological sections.

RESEARCH COMMUNICATIONS

configuration. The presence of a lateral inhomogeneity will be generally reflected in the form of a false low-resistivity layer in the ascending part of the VES curve. Once such an anomaly is noticed, two or more soundings are carried out, close to each other, along the same electrode spread azimuth at distances of about 10 to 15 m from each other. If the low-resistivity layer noticed in the VES curve is caused by a horizontal discontinuity (Figure 1a) at some depth, the current electrode separation (AB) at which the curve starts its

downward trend will essentially be the same in two or more of the offset VES curves. On the other hand, if it is due to a lateral inhomogeneity (Figure 1b and c), the electrode separations at which the low-resistivity layer begins will be offset by the respective distances between the sounding stations. The AB separation at which the low-resistivity layer occurs in these VES curves will thus clearly indicate its cause (lateral or horizontal) and its location (distance or depth).

Figure 2 shows a set of four VES curves obtained

Figure 2. Effect of a resistive lateral inhomogeneity on VES curves.

near a dolerite dyke in Veerapuram village, Tamil Nadu ($12^{\circ}44'30''\text{N}$, $80^{\circ}0'05''\text{E}$). This 20 m wide dyke is found exposed for over one km length. Three soundings are to the west of the dyke, with electrode spread direction normal to the strike of the dyke. As seen from the VES curves, a low-resistivity layer is generated whenever one of the current electrodes crosses the dyke. The $AB/2$ separation at which the anomaly begins is equal to the distance between the VES site and the dyke-country rock contact. As observed from the figure, the low-resistivity layers begin at $AB/2 = 63, 33$ and 24 m respectively in VES curves - 1, 2 and 3, thus offset by

the inter-VES station distances (9 and 30 m). This clearly illustrates the effect of a resistive lateral inhomogeneity on the shape of VES curves and the generation of a low-resistivity layer therein.

Once the presence of a lateral inhomogeneity is thus established, its strike direction can be found out by carrying out two or more sets of offset soundings along azimuths parallel to that of the first set, and joining the inferred contact zones (inset, Figure 3).

A lateral inhomogeneity thus identified can be any one of the features such as joint/fracture zone, dyke, vein, fault or shear zone. In geo-electric terms, it can

Figure 3. VES curves from Athur study area with an inferred conductive lateral inhomogeneity.

RESEARCH COMMUNICATIONS

be a resistive or a conductive layer in relation to the host rock. Both give rise to a false low-resistivity layer and differentiating the two in the field, on the basis of geoelectric parameters alone is generally difficult if not impossible. In groundwater exploration, however, it is essential that we establish the true nature of the inhomogeneity. For, a conductive zone may be water-bearing, hence the target of exploration, while a resistive body could be a massive dyke, to be avoided while locating well sites. The problem is solved by carrying out another set of soundings, but this time over the inferred inhomogeneity and with the electrode array parallel to the strike direction of the inhomogeneity. These VES curves, obtained at stations located directly over the inhomogeneity, are likely to indicate the nature of the body, by the presence or absence of geo-electric layers corresponding to relatively thick, decomposed or weathered rock zones. A resistive body (say, a massive dyke) will normally have a very thin weathered rock layer, whereas a conductive body (say, a water-bearing fracture or shear

zone) will have a comparatively thicker weathered rock layer at the top. Thus, VES curve-4 in Figure 2 shows a three-layer section with very thin weathered rock layer as expected over a dolerite dyke. VES curve-6 in Figure 3 on the other hand, shows a five-layer section, with substantially thick overburden as well as weathered and partly weathered rock horizons, indicating that underlying it is a comparatively conductive zone. This is helpful in differentiating a resistive from conductive lateral inhomogeneity.

It is possible that the lateral inhomogeneity is inclined in which case the direction and amount of the dip have to be estimated to locate the well site at a suitable distance away from the surface trace of the inhomogeneity. The ground distance to a favourable location in the down dip direction will depend on the dynamic water levels prevailing in the area—deeper the levels, larger the distance to the prospective well site for a given dip.

An empirical method of estimating the dip of the

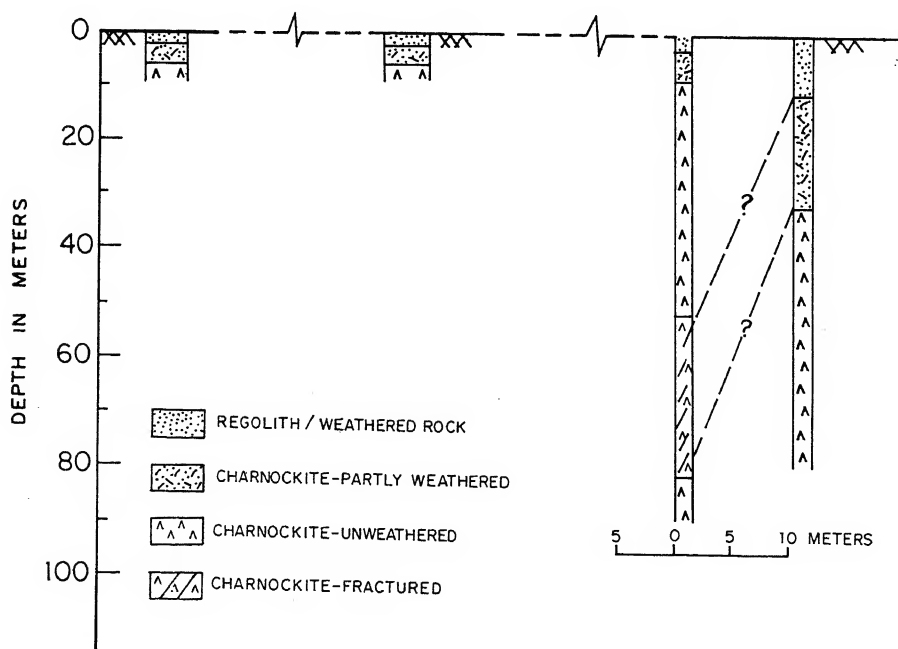

Figure 4. Subsurface geology of the Athur study area showing steeply dipping fracture/shear zone.

vertical feature is by conducting a series of soundings, in a direction normal to the strike of the inhomogeneity and with the electrode array parallel to the strike direction (Figure 3 a,b,c). A conductive zone dipping in the direction of these soundings is likely to give rise to a low-resistivity anomaly in the VES curves, and from the depths at which they are indicated in two or more VES curves, the approximate amount of dip can be estimated. Though dipping bodies can be recognized by theoretical analyses of resistivity data⁶, the methods are not unambiguous nor can they be easily adopted in field. Therefore, the empirical method suggested above is far more advantageous.

The proposed technique was tested in the field near Athur town (11°34'40"N, 78°35'14"E) in Tamil Nadu. The area is underlain by charnockite rock with a thin regolith and weathered rock zone near the surface. Several vertical electrical soundings were carried out in a grid pattern using Schlumberger electrode array, in a small plot of land for the purpose of locating a site for the construction of an agricultural borewell. Six of the VES curves obtained from this are shown in Figure 3, along with their relative locations in the inset. The presence of a lateral inhomogeneity is indicated by the false low-resistivity layers in the offset VES curves 1, 2 and 3 and confirmed in VES curves 4 and 5 from a second profile. From the position of the anomalous low-resistivity geo-electric layers in each of the VES curves, the contact of the inhomogeneity was fixed at distances of 75, 27 and 18 m respectively to the east of stations 1, 2 and 3 along the first profile and 12 m from station 4 along the second profile. The approximate strike of the inhomogeneity was established by connecting the contacts along the two profiles (inset of Figure 3). In the next step, VES-6 was carried out over the inferred inhomogeneity with the electrode spread direction parallel to the strike of the anomalous body. The results of the analysis of these six VES curves, using Auxiliary Point Charts⁷ and refined by computer simulation are given in Table 1. The quantitative interpretation is partial and approximate in the case of VES curves influenced by the effects of the lateral inhomogeneity. A marked difference is observed in the geoelectric sections indicated by curves 1 to 5 and that of curve 6. While a thick overburden ($h_1 + h_2 + h_3 = 8.6$ m) and a comparatively thick partly weathered rock layer ($h_4 = 32$ m; $\rho_4 = 135 \Omega\text{m}$) is indicated from VES-6, the depths to bed rock layer at stations 1 to 5 are much smaller, less than 2 m on an average. This sharp contrast indicates the existence of a conductive lateral inhomogeneity in the area of VES-6 which could be interpreted as a water-bearing shear/fracture zone.

The sub-surface lithology as observed from the dug well sections in the area (Figure 4) confirms the geological interpretation of geoelectric data in respect of

VES stations 1 to 5. Two borewells were drilled, one at station-6 and the second at a distance of 12 m, from station-6, towards station-3. The location of the second well was on a trial basis. The lithological sections of the two borewells are shown in Figure 4 and the drilling of the second well provided useful information.

Both borewells yielded substantial quantities of groundwater, 95 lpm (litres per minute) at VES-6 and 140 lpm from the second well. Of greater interest, however, is the lithological section thrown up by the two borewells. At VES-6 a thick overburden (10 m) is present underlain by a 24 m thick partly weathered rock zone, followed by the bed rock. In the second well, fresh bed rock was encountered at a relatively shallow depth of 9 m. In addition, a fractured rock horizon extending from 49 m to 78 m depth was also encountered in this second borewell. Much of the groundwater in case of the first well is from the weathered rock zone between 25 and 34 m, while in the second well it is mainly from the fractured rock zone, extending between 49 and 78 m depth. It has been reported that in the summer months, following the commissioning of the wells, the discharge from the first borewell reduces sharply while that from the second well sustains to a large extent. The drill cuttings obtained from the fractured rock zone in the second borewell showed distinctive polished surfaces as well as microscopic fractures, indicating that it may be a shear zone, steeply dipping from the area of VES-6 towards VES-3. The interpretation of the geoelectric data as to the presence of a conductive lateral inhomogeneity has been thus proved correct. The higher yield and its sustained nature, in the second borewell are due to the shear zone being at a deeper level, and thus remaining fully saturated even in summer compared to the near-surface aquifer zone in borewell-1. This also underscores the need for determining the dip of the lateral inhomogeneity to locate the well site at an optimum distance from the surface contact.

The methodology suggested in this paper for identifying water-bearing zones in areas underlain by crystalline rock formations is a simple, field-friendly yet effective technique, which can be applied in groundwater investigations quite successfully.

Bimal Kumar Bachhawat

An obituary

B. K. Bachhawat, one of India's leading biologists, passed away peacefully on 23 September 1996. He was immersed in scientific activity till the very end.

Bimal Bachhawat was born on 26 August 1925 at Calcutta in a large family living modestly and consisting of five brothers and three sisters. All his brothers rose to high academic and social positions in the country. His tenacity and determination for education can be gauged from the fact that he used to swim across the river Hooglee to go to school. With a Master's degree in applied chemistry from Calcutta and inspired by B. C. Guha's work in biochemistry, Bachhawat obtained his Ph D degree in 1953 from the University of Illinois. Subsequently he worked at the school of Biological Chemistry, University of Michigan, Ann Arbor, where he discovered HMGCoA lyase with M. J. Coon—a fundamental contribution to the understanding of the formation of ketone bodies in mammals.

In 1957 he joined the Christian Medical College, Vellore where he established an internationally recognized school in the area of neurochemistry and glycobiology. Bachhawat began his studies on complex and difficult problems such as glycolipids, glycosaminoglycans and glycoproteins *vis-à-vis* neural development and neurological disorder. His efforts fructified in a short duration of few years only when he and his colleagues showed that the glycolipid storage disease metachromatic leucodystrophy is caused due to the absence of the enzyme arylsulphatase A. Until then the molecular basis for about 50 glycolipid storage disease had defied understanding. Soon this pathbreaking study set the pace for the elucidation of the enzymatic defects in other glycolipid storage diseases such as Gaucher's disease and Tay-Sachs disease, which led not only to the development of their prenatal diagnosis, but also to strategies for treating such genetic afflictions. His group also elucidated the mechanism for the biosynthesis and the degradation of cerebroside-3-sulphate, the lipid stored to abnormally high levels in the metachromatic leucodystrophy patients. Subsequently, his discovery of CMP-*N*-acetyl-

neuraminic acid was crucial to defining the turnover of *N*-acetylneuraminic acid at cell surfaces. His demonstration of glycosaminoglycans in neuronal development was also far ahead of its time just as the elucidation of the role of glycolipids as biological receptors was. He also pioneered sugar-bearing liposomes as a molecular trojan horse for the site-specific delivery of drugs and enzymes to the diseased organ only. He dedicated the

last decade of his life to the development of liposomal formulations for treating systemic fungal infections which have already benefited several human beings in the country. His research was respected widely—he was one of the most cited biologists of the country.

He was the recipient of numerous awards and honours which included Shanti Swarup Bhatnagar award (1962), Golden Jubilee Medal of IISc (1976), Birla Smarak Kosh (1986), FICCI award (1982), to name a few. He was honoured with the Padma Bhushan in 1990. He was elected to all the scientific academies in India and several of them conferred many honours and medals on him over

the years. He was the first Indian to be elected to the Presidentship of the Federation of Asian and Oceanian Biochemists (1983–85) and had the rare distinction of leading the Society of Biological Chemists twice as its President (1970–72 and 1990–94). During the latter period of his presidentship, he was responsible for successfully organizing the International Union of Biochemistry and Molecular Biology. He had also organized at least ten international conferences in India for the younger scientists to have the opportunity to interact with acclaimed authorities of their field. He was also deeply involved with ethical and socio-economical issues of human genome studies and was busy organizing an international symposium to be held in New Delhi in February 1997.

Bachhawat was a great builder of Institutions as is apparent from the setting up of the neurochemistry laboratory in 1957 at the Christian Medical College Hospital, Vellore—the first of its kind in the world until recently and the Department of Biochemistry at the University of Delhi. He was responsible for making the Indian Institute of Chemical Biology, Calcutta a leading centre in the area of contemporary biology in the country. He nurtured a large number of institutions in India and was untiring in his efforts to support younger scientists. He was an inspiring researcher with a clear mind and an elephantine memory. He was fond of daily discussions with his colleagues on latest developments in science. He was always compassionate and composed even during adversity. He would enthuse his colleagues beyond their expectations even when a string of experimental failures were narrated to him and for which almost always he would apportion blame to himself for his inability to anticipate the same.

He helped, advised and encouraged younger scientists throughout the country, influenced and hastened the advent of modern biological disciplines in the country. He had a very informal and unorthodox style of administration and anyone could meet him at anytime and often obtain instant help or solutions to their

problems. He could become a youngster in the midst of young people and enjoy their jokes with boisterous laughter. He took a great delight in inviting and feeding his students and friends.

A large number of his students have earned academic distinctions both within India and outside. Bachhawat excelled in bringing people from different disciplines together to facilitate generation of novel ideas. As the Chairman of the Technical Advisory Board (Biological Sciences) of the Council of Scientific and Industrial Research, for example, he organized a large number of brain-storming sessions, on topics such as on fats and oils, membrane biology, cell surface, drug delivery, protein engineering and molecular immunology. This, in turn, led to the establishment of the molecular immunology forum which meets once a year and which has given a great impetus to the research in this area in the country during recent years. His imprint on the agencies which foster the growth of biological sciences in India will be felt for a long time.

Bachhawat was fond of Louis Pasteur's 'in the field of experimentation chance

favours only the prepared mind' and the words of Frederick Gowland Hopkins 'the biochemist should remember that his data gain their full significance only when he can relate them with the activities of the organism as a whole. He should be bold in his experiments, but cautious in his claims. His may not be the last word in the description of life, but without his help the last word will never be said.'

It is indeed difficult to describe completely an outstanding humanist like him but his warmth, affectionate and adoring nature which knew no boundaries will be missed in abundant measure by his colleagues and students for a long time to come.

Bachhawat is survived by his wife Kamala, daughters Kalpana and Kiran and son Anand.

BOOK REVIEWS

Advancements in Iron Nutrition Research. A. Hemantranjan, ed. Scientific Publishers, 5A, New Pali Road, P.O. Box 91, Jodhpur. ISBN: 81-723385-5. 1996. Price: Rs 650. 303 pp.

Agronomists and crop physiologists in India have focussed their attention since long on research in plant nutrition especially, on studies relating to mineral deficiencies in crop plants. These studies were mostly directed to the analyses of symptoms of the deficiencies.

However, little effort was made to investigate the physiological/biochemical basis of the deficiencies of macro- or micronutrients. As a result, in spite of many institutions in India working on mineral nutritions in crop plants in the past, there has been no cumulative effect on our understanding of the biochemical processes involved in mineral deficiencies in plants.

Of all the micronutrients, iron plays a vital role in plant growth and development. Fe-deficiency causes chlorosis, and this deficiency is uniquely related to the mobilization and uptake of iron by plants rather than its availability in the soil. The book *Advancements in Iron Nutrition Research* is primarily aimed at focussing this aspect of iron nutrition in plants. The editor has collected 12 review articles which mostly address soil-plant iron deficiency and control, plant root and soil contacts for iron mobilization, phytosiderophore production and siderophore-mediated iron uptake. Besides these, there are short reviews on the role of iron in symbiotic nitrogen fixation and also mycorrhizae-based iron uptake. The modes of iron-mobilization in 'graminaceous' and 'non-graminaceous' plants have been adequately emphasized. While the book contains some useful information on Fe-chlorosis, and on methods for amelioration of iron deficiency in legumes and other plants, it is neither comprehensive nor authoritative. The editor seems to have put little effort in having all the reviews in uniform style and format in presentation, avoidance of unnecessary repetitions and critical treatment of contents. While there are three articles on phytosiderophores (even though one relates to N_2 -fixing cyanobacteria), there is no in-depth discussion on the genetic and molecular-biological aspects of iron

transport across the membranes; regulations of haeme-proteins and iron-sulphur centres and flavodoxins and ferredoxin. Collecting a number of articles even though they are contributed by the leaders in the field, does not produce a good reference or a good textbook. The book *Advancements in Iron Nutrition Research* suffers from this inadequacy. The topic selected by the editor is an important one; it is quite topical. We need books that deal with plant nutritions for courses in soil biology, crop physiology, plant biology and biotechnology. Although this book contains some valuable information on iron nutrition relating to its mobilization and uptake by plants, it does not meet the needs of students and teachers or the requirements of researchers interested in basic and applied aspects of plant nutrition. The Scientific Publishers, Jodhpur, have been publishing a series of books on plant physiology and related topics. While the readers of plant sciences welcome such publications, it is quite disheartening to see poor quality of illustrations, inadequate indexing, besides printing errors.

In spite of these shortcomings, the book is a timely publication. As stated in the beginning, despite having had a lead in studying mineral deficiency symptoms in plants in India, we have lagged behind in focussing our attention to biochemical and genetic basis of the developments of iron deficiency-symptoms. We need to know the signal transduction mechanisms by which iron controls transcriptional and translational processes; iron-regulation of electron transfer and energy transduction processes. It is hoped that the readers of this book would get sufficient hint that use of cyanobacterial systems offers promises for making advances in these directions.

In short, the book therefore serves an useful purpose but it is rather costly. One hopes to see a copy of this book in college and university libraries.

The Archaean and Proterozoic Terrains of Southern India within East Gondwana – Textbook and Field Guide. M. Santosh and M. Yoshida, eds. Gondwana Research Group Memoir No. 3, Field Science Publishers, Osaka, Japan. 1996. pages xii + 403.

Gondwana Research Group (GRG) was founded recently by Masaru Yoshida of Osaka University, Japan with active participation by M. Santosh of the Centre for Earth Science Studies, Thiruvananthapuram. The GRG has already published two memoirs (Memoir 1, *Granulites of India, Sri Lanka and Antarctica*, and Memoir 2, *India as a Fragment of East Gondwana*) which have made the geological community, particularly the granulite specialists, to sit up and take notice. The Memoir 3 of the series includes a textbook (Part I, 325 pp) and field guide (Part II, 78 pp) and is a contribution to the International Geological Correlation Programme's (IGCP, UNESCO, Paris) Project No. 368: Proterozoic Events in East Gondwana.

The textbook is organized into sixteen chapters, each chapter presenting a review of some aspects of the main theme. The volume commences appropriately with Mohana Kumar's historical account of the fascinating concept of Gondwanaland from Ptolemy to Yoshida. The linkage of southern India with the Gondwanic neighbours of Sri Lanka and Antarctica (Yoshida and Santosh) and with Madagascar (Windley and Razakamanana) is the next main topic. A brief summary of the deep continental crust of India is given by Mahadevan. Jayananda and Peucat have compiled the isotopic dates of southern India. Remote sensing studies of the Proterozoic, crustal scale shear zones in southern India have been outlined by Chetty. An overview of alkaline magmatism of southern India is provided by Rajesh and Santosh. Genesis of gold, gemstone, graphite and molybdenite in Kerala is discussed with modern laboratory data by Rajesh-Chandran.

A spate of metamorphic studies follows: Karnataka-Tamil Nadu transition zone (Janardhan and Anto), Dharmapuri area (Rameshwara Rao and Narayana), Nilgiri hills (Srikantappa), Madurai Block (Anand Mohan), Trivandrum Block (Chacko, Lamb and Farquar; Santosh;

Satish Kumar and Santosh). The volume concludes with an unrelated paper on evolution of Central Indian craton by Divakara Rao and co-workers.

The field guide describes ten excursion stops chosen on the basis of easy accessibility and availability of good amount of data. Sketch maps with up-to-date descriptions of state-of-the-art laboratory information enhance the value of the field guide, which is perhaps among the best produced in recent years.

The papers are heavily weighted in favour of thermobarometry including recent studies on fluid inclusions and stable isotopes. Geochronology is also a favourite topic. While the enormous output of laboratory data will be useful for interpreting geological evolution of the region, a broad regional map showing tectonic blocks with a brief write up would have provided a good backdrop for discussion. An instructive abstract with each paper will surely have helped a rapid reader, especially in the absence of a well-organized summary. The concluding remarks or summaries given in some papers are so sketchy as to serve the author's only purpose of somehow completing his piece. A large number of papers from Kerala, particularly from Santosh's group may add to the local flavour, but may affect the reach, unless it is more broad based. When we integrate all laboratory data, it may still be necessary to verify them through field relations for which one needs more field work, which does not sadly form a significant part of new research projects.

It is to the credit of the editors and authors that the drawings are neatly and attractively done. Generally, the photographs which substitute for textual description, are not reproduced well enough. Spelling and syntax mistakes could have been reduced by more rigorous proof reading. The reference list is up-to-date, exhaustive and useful to an avid researcher. Addresses of the authors if given in the paper itself would have been very helpful. On the whole it is a

valuable compilation, useful for professionals, teachers and students.

M. RAMAKRISHNAN

*Geological Survey of India,

Calcutta 700 016, India*

Annual Review of Physiology 1996.
Joseph F. Hoffman, ed. Annual Reviews Inc., 4139 El Camino Way, P.O. Box 10139, Palo Alto, California, 04303-0139, USA. Vol. 58. Price: USA \$ 54, Elsewhere \$ 59. 815 pp.

The Annual Reviews have always been heavy reading. Each volume every year has contained several chapters; each chapter dealing with one particular branch of physiology – respiration, blood, digestion, nervous system, etc. The pattern of presentation is that each chapter is under the charge of a section editor. The section editor then decides on the particular small topic that seems to be of immense current importance in that particular branch of physiology. The current volume concentrates on molecular phenomena that affect the particular branch of physiology that is being reviewed. Thus for example, when the nervous system is being reviewed, in point of fact, the study of one specific ionic channel in the nerve cell membrane is reviewed. The whole volume is devoted to such specific molecular phenomena that are important to the various branches of physiology. Though this is an index of the importance of molecular biology in modern biological thinking, it does tend to give a very lopsided view of the subject concerned.

Given this limitation, one must view this Journal (*Annual Review of Physiology*), as meant for senior researchers, who are already working intensively in the field. Such people will find the annual reviews very useful and the reviews written by very erudite thinkers in the field. This particular issue will be of immense

value to those researchers who concentrate on molecular phenomena. Others will find the volume heavy reading and difficult to digest.

One aspect of the Annual Reviews requires special mention. The first chapter is always written by a senior researcher, who writes an informal biographical chapter, on the particular field that has been his absorbing interest throughout his life. The first chapter should be read by all youngsters (graduate or undergraduate), who intend to devote their lives to academic research. They will find themselves being introduced to the excitement and fascination of science. In this volume, the first chapter is written by H. E. Huxley. This is the man who introduced the concept of the 'sliding filament' in skeletal muscle contraction. He introduces the reader to his desire to study nuclear physics, explains why he became disenchanted with nuclear physics (the use of nuclear bomb in the Second World War), his introduction as a physicist to the study of X-ray diffraction and how he came to use this to define the molecular structure of the contractile elements of skeletal muscle. It exemplifies how a strict physicist can unravel biological secrets and positively direct the thinking of biologists. As far as this volume of the *Annual Review of Physiology* is concerned, this particular chapter by H. E. Huxley focusses the reader's mind onto the need for understanding many biological phenomena at the molecular level.

By and large, this journal contains reference material, useful to the senior researcher. It also contains one chapter that will inspire the youngster. This journal should be stocked by every library that deals with biology. Individuals should only buy those volumes that are of particular interest to them.

GOVERNMENT OF INDIA

DEPARTMENT OF SCIENCE & TECHNOLOGY

Programme on Nonlinear Phenomena, Complex Matter and Biologically Inspired Physics

The importance of nonlinear science, soft condensed matter (such as colloids, powders, polymers and membranes) and biologically inspired physics has emerged very clearly in recent years. In view of this and given the large mutual overlaps of these disciplines as well as their interdisciplinary nature, the DST has considered it fit to constitute a separate Programme Advisory Committee (PAC) specifically to foster research in these areas. Suitable project proposals are invited in the above general fields.

Research proposals should pay particular attention to the development and application of ideas and techniques that cut across disciplines and/or seek to elucidate and provide insight into the general paradigms of complexity and nonlinearity.

Proposals that come under this general purview include:

Dynamical phenomena far from equilibrium, driven systems, chaos, especially spatiotemporal. This encompasses both model systems such as sandpiles and driven lattice gases as well as 'real' examples such as colloids in shear flow and sedimentation, turbulence, kinetics of phase ordering, granular matter (powders), earthquakes, pattern formation, etc.

Physics of soft condensed matter. Membranes (biological and model), Langmuir monolayers and Langmuir-Blodgett films, micelles, vesicles, lamellar structures, microemulsions, emulsions, foams, and other structures in surfactant solutions: liquid crystals, both thermotropic and lyotropic, polymer solutions, gels, and melts: colloidal suspensions, including ferrofluids, electro-rheological fluids, etc.

Biologically inspired physics. Models in evolutionary biology and population genetics, evolution of complexity, neural networks, optimization, protein folding, motor proteins and molecular ratchets, etc.

Qualified researchers interested in submitting project proposals to be considered for funding may write to the following address for further details:

INDO-AUSTRALIAN SCIENCE & TECHNOLOGY COLLABORATION PROGRAMME

Department of Science & Technology (DST), Government of India invites applications from scientists for financial support under the Indo-Australian Science & Technology Research Programme for exploratory visit of up to 14 days with an objective to develop joint research projects in the areas of Medical Science and Human Nutrition; Food Technology; Energy (including Renewable Energy); Environmental Management and other theme areas which might meet national interest.

2. While considering proposals, particular importance will be given to the scientific gains for India & Australia and where these could be applied to industry. Preference will be given to the proposal which has the consent of both Indian and Australian partners and is likely to result in a joint research project for a period of 2-3 years.

3. Financial support will be limited to return international airfare travel from DST. The Australian Department of Industry, Science & Tourism (DIST) would provide A\$ 150/- per day towards accomodation, boarding and out of pocket expenses to the visiting Indian scientists under this programme. Funding for equipment, bench fees, institutional overheads, etc., will not be provided under this programme. Application forms along with guidelines for such collaboration may be obtained from the following address:

Shri S. K. Varshney, Senior Scientific Officer, International Division,
Department of Science & Technology, Technology Bhavan, New Mehrauli Road,
New Delhi 110 016

TEL: (011) 662135, 6962819; FAX: (011) 6862418, 6863847

E-mail: apk@alpha.nic.in. or apk@udst.sirnetd.ernet.in.

4. Requests for applications may be made latest by **15 February 1997** alongwith a *self-addressed unstamped envelope*. The visit proposal completed in all respects should be submitted latest by **28 February 1997**.

COVER. The queen and her 'court' – a honey bee queen surrounded by a retinue of worker bees who lick and feed her and while doing so receive and redistribute pheromones produced by her (Photo by Kenneth Lorenzen, University of California, Davis). What makes the queen special appears to be a keto group in the major component of her pheromone blend. See page 975.

Indexed in CURRENT CONTENTS/GEODATABASE/CHEMICAL ABSTRACTS

In this issue

Chemistry, caste and honeybees

Does chemistry determine behaviour? Undoubtedly so, but rarely do chemists and behavioural biologists find a common meeting ground. In a speculative paper in this issue, Gadagkar (page 975) asks a provocative question, 'What is the essence of royalty' that determines the queen in a honey bee colony? The answer appears to be provided by a recent paper by Plettner *et al.* (*Science*, 1996, 271, 1851-1853), which examined the mandibular gland secretions of queen bees and workers. Interestingly, the secretions which contain hydroxylated, unsaturated fatty acids differed only in the position of the carbon atom that is hydroxylated. The differences arise because of a 'caste-specific bifurcated pheromone biosynthetic pathway' for the production of these compounds. The major pheromone produced by queen bees is 9-keto-(E)2-decenoic acid (9-ODA), a compound with a name far more formidable than its chemical structure. This substance differs from the major component of the worker pheromones, which lack the carbonyl group at position 9; tempting Gadagkar to state emphatically that the 'essence of royalty is just one keto group'.

Caste-specific biochemistry in social insects like honey bees provides a chemical rationalization of the differentiation between the queen and workers in a colony. The remarkable phenomenon of colonies that contain 'thousands of sterile workers, a few hundred drones and a single fertile female, the queen' has fascinated sociobiologists for a long time. Several questions remain to be addressed,

the most obvious being - who came first, the queen or the worker? In considering this problem Gadagkar returns to the reactions of pheromone biosynthesis and argues that pathways in workers appear to be more 'ancestral' while that in queens which result in 9-ODA appear to be more 'derived'. His thesis is based on the argument that the production of the keto acid (9-ODA) is 'energetically unwise', thereby suggesting a more important motivation than mere production of energy by oxidative metabolism. There are many fascinating issues to be considered, not the least of which is the evolution of sociality. Queen bees can indeed 'be thought of as an invention of sociality'.

Gadagkar uses this essay on the essence of royalty to emphasize that the failure to make distinctions 'between proximate physiological explanations and ultimate evolutionary explanations' leads to 'unnecessary confusion as to what constitutes a valid answer to the question of why an animal does what it does'. The biochemical analysis of 'caste-specific' pheromones in honeybees by Plettner *et al.* is a marvellous example of the interplay between 'proximate and ultimate factors'. Gadagkar concludes with an Utopian vision where evolutionary biologists become biochemists and vice versa. It would appear that there is still life in lipid biochemistry.

Revolutionizing life science education

Most scientists and educationists appear to agree that all is not well

with the state of university science education in India. Academies have pondered over the issue and there have probably been many eminently forgettable reports commissioned by successive generations of planners and governments. The National Science University proposal which aroused an extended debate in this journal, highlighted the widespread concern that science education in universities needs a dramatic reorientation. In an article on page 960, Modak details a proposal for an integrated 5-year M Sc course in life sciences. The growing importance of the biological sciences and the high hopes that have been raised by the ongoing biotechnology revolution, emphasize the importance of focussing on this area. Modak's proposal for integration of various subdisciplines will find an echo in other areas of science. Few will quarrel with the synthetic approach espoused by Modak and none will argue with the need for favouring inventiveness in students. However, a sobering thought is that we have rarely been short of good solutions on paper to important problems. The real difficulty lies in implementing any new programme, cutting through thickets of resistance to change. In a strongly worded postscript, Modak argues that his suggested experiment in education should be supported 'because it is revolutionary and original. It is a direct attempt to replant the cured soil of higher education in science with an epigenetically modified and better-yielding variety.' Deeds must follow words.

SUBMISSION IN ELECTRONIC FORM

Authors who have been informed of acceptance of their manuscripts may send the final version in electronic form on floppy diskette (3.5" preferred; IBM PC format only, *not* Macintosh). The text of the manuscript only should be supplied as a plain ASCII file with no formatting other than line and paragraph breaks. (Wordstar 5.5 or 7.0 and Microsoft Word for Windows 6.0 are acceptable, but ASCII is preferred.) A hard copy of the text, with all typesetting information (italics, bold, mathematical type, superscripts, subscripts, etc.) must accompany the electronic copy. Tables and figures must be supplied only as hard copy. The diskette must be labelled clearly with the following: manuscript number, file name, file information (ASCII or Wordstar, version number, etc.).

Text may also be transmitted as ASCII only by e-mail to currsci@ias.ernet.in.

We expect that electronic submission will result in quicker processing for publication.

CORRESPONDENCE

Observation on urban rhesus monkeys

Certain ecological aspects and behaviour patterns of urban rhesus monkeys (*Macaca mulatta*) that I observed as an amateur might be of interest to some of your readers and those interested in investigating related problems in nature.

For more than four years, two rhesus monkeys (1 male and 1 female) inhabited certain localities of north Calcutta and exhibited some interesting foraging patterns.

While raiding my roof-top Bonsai garden every day during two seasons each year (just prior to the monsoon and again just before winter), they fed on the fleshy inner side of exposed roots of *Salmalia*, the bark of *Terminalia arjuna*, and all parts of *Ocimum sanctum* except its roots. *Andrographis panicu-*

lata, which has a bitter taste, was also taken by them.

It is interesting to note that all these plants are medicinally important. Moreover, they also appeared to specifically consume those parts of the plants that are known to be medicinally useful. It is also noteworthy that none of the plants on which the monkeys fed died as a result of injury. They did not totally destroy any plant during any of their visits and also did not attack any particular plant on consecutive days. The fact that, in the course of 4 years, these limited resources were not exhausted is possibly significant. It should be of interest to note whether free-ranging monkeys display such sustainable exploitation of natural resources.

In course of their feeding, the monkeys also dispersed the seeds of *O. sanctum* and *A. paniculata*, thus compensating to some extent the loss that was inflicted.

Last year, the local police took away my study subjects. Soon, however, the empty niche of the rhesus was filled by human langurs (*Presbytis entellus*) who had not invaded the area during the last 4 years. In comparison with the rhesus monkeys, the langurs were far more destructive and did not exhibit any of the features of limited resource exploitation shown by the former.

Technological advances in the biological control of insects

Biological control, the corner stone of Integrated Pest Management (IPM), along with host-plant resistance is central to the pest management paradigm. To be more effective, it has to integrate diverse programmes involving natural enemies and microbials (bacterial, viral and fungal), besides kairomonal elements from host insects. With the advent of efficient, high quality mass rearing and delivery system and the ecofriendly, biorational techniques involved in microbial control, biological control has come to be considered as a

technology-oriented exercise. Timely production of the highest quality material supported by adequate research, development and technology transfer become very relevant to efficient biological control. Interest in these aspects has led to increased commercialization of biocontrol production highlighting the need for a healthy competition among entrepreneurs. With this background, a symposium on 'Technological advances in the biological control of insects' was organized at the Entomology Research Institute on October 11

and 12, 1996 to take stock of the existing technologies and suggest modifications where needed.

M. S. Swaminathan (MSSR Foundation), in his inaugural address, highlighted the advances and progress made in the 'Green Revolution' era in increasing the food production in India particularly during the last 30 years. Swaminathan cautioned the entomologists on the use and abuse of chemical pesticides and the current problems with high input, high tech agriculture. He desired that a blend of host-plant resis-

tance and biological control would sustain in checking the pests of crops and that a relook into the whole gamut of pest management would be rewarding in the years to come. Swaminathan also emphasized the need for integrating information technology with Integrated Pest Management (IPM) to fill the gap in spreading the IPM. He suggested that use of computers to educate and spread the knowledge among farming community must be given due consideration. This would result in group action and would educate the farmers and bio-environmental management of agroecosystems.

T. N. Ananthakrishnan (Entomology Research Institute, Loyola College, Madras) in his introductory remarks indicated that though mass rearing has become a routine technology, increased efficiency and mechanization of beneficial arthropod production are important for future success of augmentation. To be effective the natural enemies have to be retained in target areas with prospects of efficient location of hosts and as such technology for managing the environment becomes equally important. Future challenges for developing augmentation technology exist in such areas as mass rearing, quality control, storing and application. Quality control has such components as production standard, production facility and monitoring the performance in the field. Production efficiency and field performance of natural enemies depend upon diverse parameters such as survival of immatures, size, fecundity, sex ratio, longevity and host-seeking ability. Maintenance of genetic variability is another component of quality control in mass rearing involving, hybridization of field collected material with that from laboratory line. Interinstitutional co-operation is vital for the success of commercial natural enemy production as well as maintenance of ethics in the production and distribution of natural enemies.

T. M. Manjunath (Pest Control (India) Ltd. Bangalore) emphasized that with the increasing significance of biological control as the foundation of integrated pest management, there is a growing demand for biocontrol agents. The success of such programmes depends mainly on the efficient and economic mass-production, ready availability, timely application and adequate releases of quality biocontrol agents.

Recent advances made in the *in vivo* and *in vitro* rearing technology for biocontrol agents like *Trichogramma* and other parasitic wasps, *Chrysoperla*, ladybird beetles, phytoseiid mites, indicated this trend. Progress has been made in the methods of packing, storage and application techniques of natural enemies and the role of commercial insectaries and other organizations, including extension agencies, in transferring and popularizing the biocontrol technology and IPM, is commendable.

Speaking on the commercial production of biopesticides, M. Swamiappan (Tamil Nadu Agricultural University, Coimbatore) indicated that about 35 biocontrol agents comprising predators, parasitoids and insect pathogens have been found to be very promising and amenable for mass production and field use. A healthy competition among entrepreneurs is required so that biopesticide production units will be playing, an effective role in making available quality and cost-effective products for the farming community. Quality control norms are to be standardized for each and every product as they are living biocontrol agents. Streamlining is necessary in this new line of entrepreneurship by generating documents for registration, data for quality control, consideration of certain ethics and code of conduct for the production so that the real concept of biological control is perceived in order for the goals and aims to be achieved.

Highlighting the need for improved technology for mass rearing of Trichogrammatids and their factitious host *Corcyra cephalonica*, Navarajan Paul (IARI, New Delhi) opined that mass production of suitable factitious host is an important component in any biological control programme so as to ensure timely production of sufficient quantity of natural enemies for field releases. Among the factitious hosts, the Rice Meal Moth is an important factitious host that is multiplied all over the country for production of various natural enemies including Trichogrammatids. Studies indicated that the progenies of *Trichogramma chilonis* and *T. exiguum* reared on the eggs of *C. cephalonica* recorded higher fecundity and longevity as compared to those reared on *Sitotroga cerealella*. The present method of mass production of *Cor-*

cyra cephalonica is labour intensive and the labour involved in the mass production is amenable for exposure to the moth scales which are known to cause allergic reactions in many individuals. A Close Type Rearing System has been developed in which exposure of the workers to moth scales is minimized and the manual moth collection is totally eliminated. Among the rearing media used for larval rearing, maize was found to be the best, resulting in high productivity moths and better quality of the egg parasitoids. A simple cleaning device for removal of scales from *C. cephalonica* eggs was developed with a cleaning efficiency of 95%. With the use of modified oviposition cage that could be fitted below the Closed Type Rearing System, eggs could be cleaned directly without exposing the worker to scales with a cleaning efficiency of 99%. A manual operated egg card making machine has been fabricated in which *Corcyra* egg cards containing approximately 1 ml of eggs, could be prepared in six seconds. Exposure of *Corcyra* egg cards containing 0-24 h old eggs for 2 minutes to UV radiation from a 30 W lamp from a distance of 5 cm sterilized the host eggs completely, thereby eliminating the larval hatching from unparasitized eggs. A suitable illumination chamber to provide 100 lux light intensity was developed for efficient parasitoid rearing. A parasitization chamber, in which 20 ml of eggs could be exposed simultaneously for parasitization, was developed which resulted in uniform parasitization and lesser proportion of runts at 1:7 mother to daughter card ratio with an exposure period of 48 h. The economics of mass production of *T. brasiliensis* both by conventional and improved methods was worked out considering an average production of 70 ml *Corcyra* eggs per day.

D. N. Yadav (Gujarat Agricultural University, Anand) discussed the mass rearing techniques for the predators *Chrysoperla cornea* and *Mallada boninensis* developed by using eggs of rice moth *Corcyra cephalonica*. The techniques involved (1) Larval rearing in a group in a round galvanized iron sheet cage, (2) Two-phase larval rearing in multicelled plastic louvers, (3) Single phase larval rearing in Biotech Bioassay trays. The feasibility of these rearing

techniques was tested for both the species. Results revealed that larval rearing in bioassay trays and two-phase larval rearing in multicelled plastic louvers proved effective for both the species. In the case of *C. carnea*, the percentage adult recovery was maximum (90.23) when larvae were reared in biotech bioassay tray followed by two phase larval rearing in multicelled plastic louvers (75.64%) and group rearing of larvae in round galvanized iron sheet cage (55.7%). In the case of *M. boninensis* when larvae were reared in biotech bioassay tray, the adult recovery was 71.56% followed by larval rearing in multicelled plastic louver (67.09) and group rearing (13.91). The data on fecundity, longevity, genetic deterioration, egg production, storability of the predator at low temperature are given. Advantages and disadvantages were also discussed.

Referring to the role of entomopathogenic nematodes in the biological control of insects, C. V. Sivakumar (Tamil Nadu Agricultural University, Coimbatore) indicated that species of *Steinernema*, *Heterorhabditis bacteriophora* and *H. indicus* have established in Tamil Nadu, and the bacterial symbiont associated with *Steinernema* sp. closely resembles *Xenorhabdus poinarii*, while *X. luminescens* is associated with *H. indicus*. The virulence of *S. carpocapsae* and the native isolates has been established against a number of major insect pests. Plant host-induced variation in the susceptibility of *Spodoptera litura* larvae to *S. carpocapsae* exist. Virulence of *S. carpocapsae* is altered by the host insect on which it multiplies.

Foliar application of *S. carpocapsae* has been found effective against the groundnut leaf miner, *Aproaerema modicella* on groundnut and *Spodoptera litura* on sunflower. Addition of a phagostimulant to nematode spray suspension increases the effectiveness of *S. carpocapsae* against *S. litura*.

K. S. S. Nair (Director of Kerala Forest Research Institute, Peechi, Trissur) discussed the new design of a light trap, in view of biological control operation requiring more accurate monitoring of pest populations. An indigenously designed novel light trap, powered by a Solar Photovoltaic (SPV) System for use in remote areas where electricity is not available, was discussed. The light

source is a 20 V 'black-light' tube which is switched on automatically at dusk, controlled through the SPV system facilitates automatic operation for pre-set periods. The insect can be trapped into a bottle or a net-covered, walk-in chamber from where live insects can be selectively collected. Efficiency of the trap is reported on the basis of taxa of insects collected. The trap has several advantages over conventional light trap-facility to operate without electricity, operation for specific time periods, use of a black-light tube for greater effectiveness and facility for collection of live insects. A portable model with a 12 V black-light tube has also been developed and is under test.

S. Jayaraj (MSSR Foundation, Madras) highlighted the importance of Nuclear Polyhedrosis Virus (NPV) isolated from two ecosystems in Tamil Nadu, from the points of view of its pathogenicity, safety, bioefficacy, shelf-life, mass culturing techniques and field release. The virus biopesticide shows great promise in *Helicoverpa* management. Various methodologies concerning the establishment of laboratory colony of the pest, insect culturing techniques, equipments and materials needed for (a) Adult handling, (b) Egg collection and storage, (c) Egg sterilization, (d) Egg/larval handling, and (e) Pupal harvest and storage were discussed. The ingredients and methods of preparing semi-synthetic diet for the larvae were highlighted. Egg surface sterilization techniques and adult handling methods were explained, and methods of culturing NPV in the host insect and the extraction, purification and formulation of the virus also discussed. The standardization and quality control of the NPV were given much emphasis (Figure 1).

N. Ramakrishnan (Indian Agricultural Research Institute, New Delhi) discussed the growth of polyhedrosis virus in silk worm tissue culture, which provides a useful technique involved in tissue culture and difference cell lines can be developed and employed for various forms of biological research besides production of insect viruses. To date a total number of 1600 viruses have been reported, causing diseases in about 1100 species of insects and mites. About ten insect viruses (nuclear polyhedrosis viruses and granulosis viruses)

are used in large scale which are produced on the living host. The accompanying technological development in this form of production are (i) effective and cheap mass rearing media for host insect, (ii) automation in mass rearing of the host including inoculation and collection of viruses, (iii) quality control, standardization and formulation, (iv) the application technology and (v) marketing strategies. The possibilities of increasing the production of the virus by administering the host larvae with methoprene and improving the efficacy by genetic manipulations are discussed. Constraints in *in vivo* production were also explained.

R. J. Rabindra (TNAU, Coimbatore) explained that insect culture technology along with molecular techniques is currently being extensively used in developing improved viral pesticides which can give a boost to biocontrol. The successful development of baculovirus expression vector systems has given an impetus to the development of cell culture technology and consequently baculoviruses have emerged as promising ecofriendly pest management agents. Insect cells are routinely used for cloning of viruses, development of mutants and viral strains with desirable attributes like enhanced virulence and persistence. Recent advancements in molecular techniques have enabled the construction of recombinant viruses with greater pest control potential. The most crucial process of cotransfection of the cloned DNA and the wild type viral DNA takes place in insect cells grown in a suitable medium. Commercial application of the baculovirus expression vector system has opened the avenue for large-scale production of insect cells through liquid fermentation technology and *in vitro* production of viruses in insect cells. Various *in vitro* techniques have been developed for increasing cell yields and optimising virus production. Cell fusion techniques may provide hybrid cells capable of yielding greater amounts of virus.

P. Narayanasamy (Annamalai University, Annamalai Nagar) highlighted technological aspects of mycoinsecticides. Fungi, in particular, are reportedly very effective against the brown planthopper (BPH) and other pests of rice as field ecosystem is quite conducive for the fungal parasite. The fungi which were predominant included,

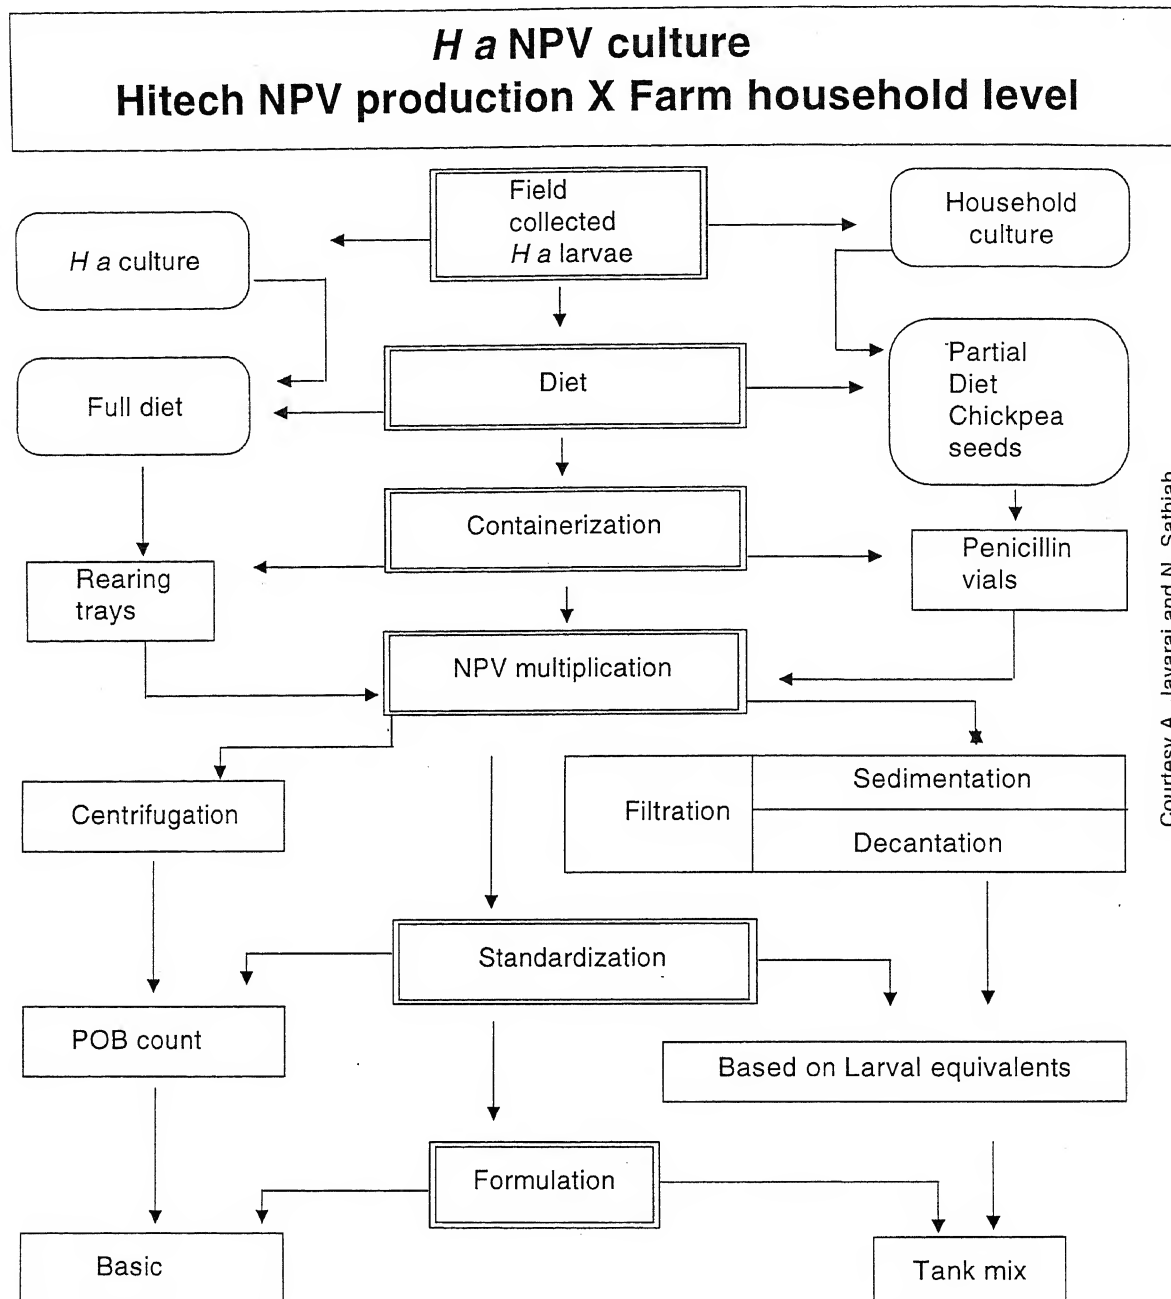

Figure 1.

Pandora delphacis, *Metarrhizium flavoviride* var. *minus*, *Beauveria bassiana*, *Zoophthora radicans*, *Nomourea rileyi* and *Paecilomyces farinosus*. The fungus *Pandora delphacis* which occurs in many districts of Tamil Nadu is a potential cure to the BPH menace. Hence the pathogen, after checking for various cultural characteristics was subjected to development as mycoinsecticide.

Two mycoinsecticide formulations such as dust (10%) and wettable powder

(70%) were prepared with broken sorghum. These formulations were evaluated under field conditions. Of these, mycoinsecticide 70% WP was found to be more potent in killing the BPH to 66.15% than other treatments tested. Moreover, efficacy of the formulation was found uniform when tested at Coimbatore, Mandya and Hyderabad. It is significant that the cost of a kilogram of the product is only Rs. 10/-, which is far less than the chemical insecticides. The potential for the use of mycoinsecticide

appears more valuable for pest problems of rice plant and hence it needs encouragement and mass use by the farming community.

S. Uthamasamy (Tamil Nadu Agricultural University, Coimbatore), coordinating the discussions, laid stress on such aspects as quality control in biological control; improvement of technology; new area of research; registration of biocontrol products/laboratories; training and implementation technology and industry/institute inter-

actions. S. Jayaraj presided over the concluding session which generated newer ideas in the area of biocontrol technology.

Quality control in biological control

Spurious materials, adulterations, substandard and poor genetic stocks are being marketed and it was suggested that there should be a network system within the All India Coordinated Research Project on Biological Control of Crop Pests of ICAR, State Agricultural Universities (SAUs), ICAR Institutes to monitor the quality of the biocontrol products marketed in our country. Further, the ICAR, Department of Biotechnology (DBT) and State Departments of Agriculture should enforce this aspect of biological control which would go a long way in improving the quality of biocontrol products.

Improvement of technologies

The urgent need for improving the existing technologies was also stressed, variations in the effectiveness of existing biocontrol products, arbitrary recommendations and very poor impact of such products on target pests are re-

ported. Hence, an earnest effort should be made to refine the technologies which would sustain the momentum gained in this area of biocontrol.

New area of research

A very large number of natural enemies are available for exploitation in the management of pests. The biocontrol potential of reduviids, anthoreids, spiders need to be studied. Further, new pathogens such as fungi, bacteria, nematodes offer scope for research and a need to be studied. Recent reports indicate that poly DNA viruses suppress the immunological reactions of the host and hence there is need for initiation of research in this area.

Registration of biocontrol products/laboratories

There is need for regulating the mass production of biocontrol agents to enable the farmers to get quality products from registered laboratories. A guideline on quality parameters, storage, transport and field release should be supplied along with the products for the benefit of users. This would educate the farmers on proper handling of these

products for effective check of the target pests.

Training and implementation technology

Farmers, involved in the production and use of biocontrol agents should be trained by institutional trainings, farm-based trainings and other innovative approaches would spread the message of biointensive approach in pest management. The communication media and computers should be utilized to the maximum extent in educating the people. Software for biological control targeting crop-based approaches *vis-à-vis* pest-based approaches would pay rich dividends.

Industry/institute interactions

An effective interaction between agro input industries and research organizations in promoting the concept of biological control would be useful, as we enter a new era of pest management in the 21st century.

T. N. Ananthakrishnan, Entomology Research Institute, Loyola College, Madras 600 034, India

Discovery of a new effect: CFM effect

S. K. Ghosh

A report on the discovery¹ of a new effect, named Continuous Frequency Modulation Effect (CFM effect) is reported here. The CFM effect occurs in the power spectrum of oscillators undergoing a continuous modulation of the vibrational frequency. Agrawal *et al.*¹ have shown that a single sharp line, normally characteristic of an oscillatory system, broadens and exhibits a wealth of fine structure components when the system undergoes a continuous frequency modulation. Then also gives the relationship between the fine structure and the frequency modulation rate. The fine structure so observed has been termed as the 'CFM fine structure'.

For an analytical justification of the CFM effect, the authors present a detailed mathematical treatment of a pulse, $Y = A \sin \omega t$, of duration T such that ω is continuously varying with time:

$$\omega = 2\pi\nu_0 (1 - kt).$$

If the pulse duration T and the frequency modulation rate constant k are such that $2kT < 1$, then it is shown that the power spectrum of such a pulse exhibits CFM effect – the existence of a wealth of fine structure components. Further, it is shown, numerically as well as analytically, that the position of the fine structure extrema depends linearly upon the initial oscillator frequency and the square root of the absolute value of the modulation rate. The peak-to-peak spacing is shown to be proportional to the square root of the absolute value of the modulation rate.

Such CFM effect has been experimentally observed by the authors while the resonant frequency in the NMR studies

is continuously changed by varying the main magnetic field B with time. In this connection, the authors also suggest a method of identifying the electronic transients in an NMR spectrum by using the CFM effect. The authors write: 'This observation suggests a method for identification of such transients in a complex NMR spectrum. One simply removes the field lock and takes an NMR spectrum with B varying. All the NMR lines will broaden and split, but the electronic transients will be unaffected. Once identified they can be safely subtracted from the NMR spectrum.'

The CFM effect has also been verified by a computational study of different types of oscillators such as harmonic system with an exponentially modulated frequency with and without amplitude depression.

In several classical trajectory studies of chemical reactions, it has been observed in the past by different research groups that the power spectrum of a molecule transferring vibrational energy during a reaction contains unexplained fine structure. Agrawal *et al.* point out that with the help of the CFM effect not only is the fine structure explainable, but one can also deduce the rate of energy transfer by the molecule from the knowledge of the CFM fine structure.

Such a point has been presented in detail by correlating the rate of vibrational energy transfer with the rate of frequency modulation rate and the computed CFM fine structure for different diatomic molecules vibrating under the influence of the Morse potential.

For the application of the CFM effect to the molecular reaction dynamics, the

authors discuss three examples: (1) Determination of vibrational relaxation rate coefficient from the knowledge of the CFM fine structure in a computational study of HONO in a cryogenic rare gas matrix, (2) The use of CFM effect to extract the rate of energy transfer from a diatomic molecule to a surrounding matrix cage of Ar atoms, (3) The instantaneous energy transfer rate from the knowledge of the CFM fine structure. However, the CFM effect may not be applicable in the molecular systems if the vibrational frequencies cannot be continuously modulated due to the constraints imposed by quantum mechanics.

Since the CFM effect is applicable whenever there is a continuous frequency modulation of a vibrating system, it becomes an effect of fundamental importance and its application cannot be limited to a few cases. It may be of importance in Physics, Chemistry, Electronic-engineering, Astrophysics, and many such disciplines where the vibrational frequencies are continuously modulated even for a short duration of time. Further, from the point of view of research in mathematics, the CFM effect widens the scope of research in the Fourier transform of different types of functions representing vibrations with continuous frequency modulation.

Research Snippets (compiled by A. V. Sankaran)

The parting of Indo-Australian plate

In the past two decades, scientists have been noticing certain abnormalities in the lithosphere south of India which forms part of the northward drifting

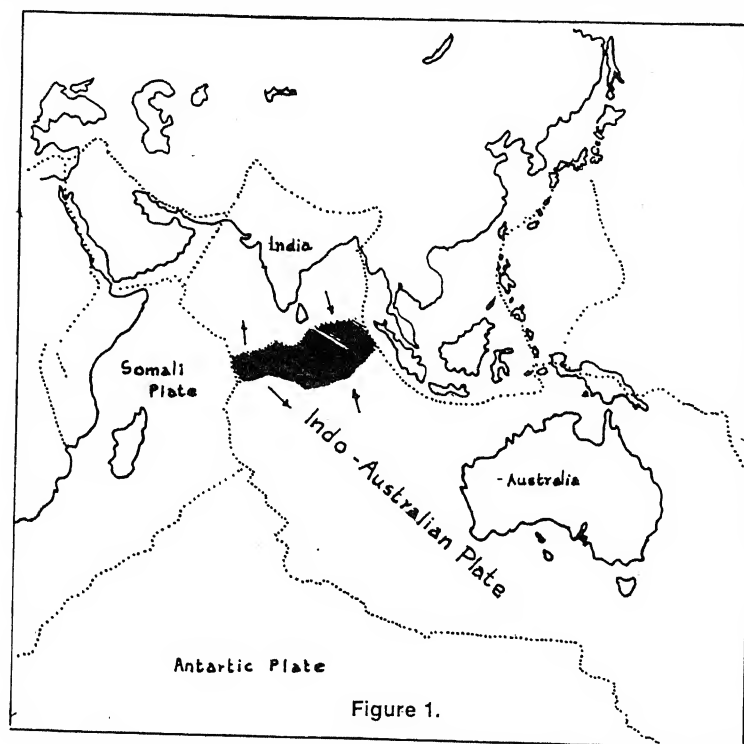

Figure 1.

Indo-Australian plate. This area, which is almost in the central portions of this plate, was exhibiting signs of deformation or crumpling – a feature normally associated with tectonic plate edges only (Figure 1). A team of workers – James R. Cochran (now in MIT), J. K. Weissel of Lamont-Doherty Earth Observatory and Florence Jestin of Ecole Normale Supérieure (Paris) investigated data¹ gathered during oceanographic expeditions in 1986 and 1991 and from a study of faults in the ocean bottom, they have calculated that India and Australia are currently moving in different directions and hence must be sitting on separate plates. They have even calculated that the deformed lithosphere is nearly 900 km across – wider than the borders between other tectonic plates and that the split was formed during the last 8 million years. If confirmed, the new studies would bring the number of major plates to 17.

1. Lamont-Doherty, *Sci. News*, 1995, **148**, 123.

Archaeopteryx – No more oldest known bird

Some new finds of avian fossils from Liaoning Province (NE China) and nearby Korea dating back to the Jurassic have shed fresh light on trends in bird evolution. These fossil finds described¹ by Chinese and US palaeontologists, are believed to pre-date *Archaeopteryx*, the oldest bird fossil discovered in 1861 from shales in Bavaria (Germany). The new fossil bird, about the size of a pigeon, named *Confuciusornis sanctus* has features which are a blend of modern and Jurassic times. Its toothless, horny beak, feather-covered legs which are short above and long below the

knee – features that were thought to have developed in birds only during Cretaceous and later times – make this Chinese fossil find closer to modern birds. But the design of the forelegs and long recurved claws on the feet suggestive of its arboreal habit are more allied to *Archaeopteryx*. These discoveries are considered to be very exciting inasmuch as they have questioned existing views of *Archaeopteryx* ancestry to modern birds and have pointed to possibilities for other side branches to the avian tree of which *Archaeopteryx* branch, perhaps, is one, but which apparently met

with a dead end. These finds lead to an obvious conclusion that if birds were already diverse in Jurassic, the still more primitive of the species must have taken to wings as early as late Triassic – some 60 million years before *Archaeopteryx* flapped in the Jurassic skies.

Yellow fever threat?

In the wake of dengue and dengue hemorrhagic fever (DHF) epidemic in Delhi and neighbouring states, there is a heightened concern among the public health experts of the possible outbreak of yellow fever in the Indian sub-continent. This lurking fear emerges from the global experience in the emergence and re-emergence of at least 30 infectious diseases¹. Yellow fever virus belongs to flavivirus group, and other members of this group have already entered India and gradually assumed epidemic proportions as exemplified by the appearance of DHF in Calcutta in 1963 and Japanese encephalitis (JE) in North Arcot Dist., Tamil Nadu in 1958. These diseases moved from east towards west, and have now occupied vast territories throughout India, thus raising an alarm of the possible future scenario of communicable diseases and exposing the public health preparedness and monitoring capabilities. Other examples are the re-emergence of once-decimated diseases like kala-azar and malaria, the recent epidemic of plague, and emergence of drug-resistant parasites, vector resistance, and ecological succession of vectors with better adaptations. Tropical climate and environmental degradation makes India a hot bed of new infections and, therefore, warning signals for yellow fever are already there. Vector control which was so successful in the control of communicable diseases has unfortunately taken a back seat. The entomological component in most public health programmes in the endemic countries is the weakest and often non-existent, whereas vector control still remains the most effective and rational approach to vector-borne disease con-

trol. Endemic countries will do well by giving entomology its due place in the public health programmes. What makes India vulnerable to yellow fever are an unprecedented increase in *Aedes aegypti* populations due to urbanization, industrialization, water storage practices, rural water supply and population migration. *Aedes aegypti* 'type form' and var. 'queenslandensis' are sympatric² and both are potential vectors as demonstrated by transmission studies³. Similarly *Ae. albopictus* is susceptible to yellow fever virus⁴. *Ae. aegypti*, breeds in containers, rain water collections and invades new territories through used tyres and solid waste dumps and finally diffuses through piped water supply and then proliferates, whereas *Ae. albopictus* is sylvatic and native to India. This mosquito invades peripheral wooded areas and gardens in urban areas. Indian are susceptible to yellow fever as they lack antibodies⁵. Virus invasion is a possibility through the large volume of traffic from yellow fever endemic countries in Africa and South America. Although yellow fever has not moved to any other continent, there is a geographical spread from west coast to east coast of Africa, south of Sahara. There is, therefore, a possibility that large-scale population movement, ecological upheavals, population explosion and developments for better living may break these barriers. Furthermore, quarantine health checks and special sanitation measures introduced under the International Health Regulations⁵ to prevent yellow fever entry through air and sea ports into India are not functional. Once the virus enters India either through infected humans or the vector, it can spread through

the local vectors. Indian monkeys, viz. *Macaca mulatta mulatta* and *Macaca radiata* are susceptible to yellow fever virus and *Ae. albopictus* can maintain a zoonotic cycle and become a lasting source of infection. To prevent this from happening, quarantine health checks and *Aedes* control measures should be applied rigidly and introduced at all ports of entry in the Indian sub-continent. A surveillance system should be developed to monitor vector populations and the antibody profile in the indigenous populations. Municipal and building bye laws should be adapted and implemented uniformly throughout the country to control vector breeding on sustainable basis. Solid waste disposal should be managed professionally. Emergency strategic planning and adequate stocks of vaccines and drugs should be at hand to fight the accidental entry of new diseases such as the yellow fever.

Occurrence of a 'fossil' crocodilian vertebra from Hassan District, Karnataka State – A preliminary report

The fossils were recovered accidentally during levelling operation by a bulldozer prior to the agricultural activities in Mosale Hosahalli village, Hassan

Taluk and District (Figure 1). This was brought to our notice by one of our students of the same area who also helped us in collecting the samples.

From our observation about the material, it is unlikely that the material was originally in the present place and that it was found *in situ*. It might have been

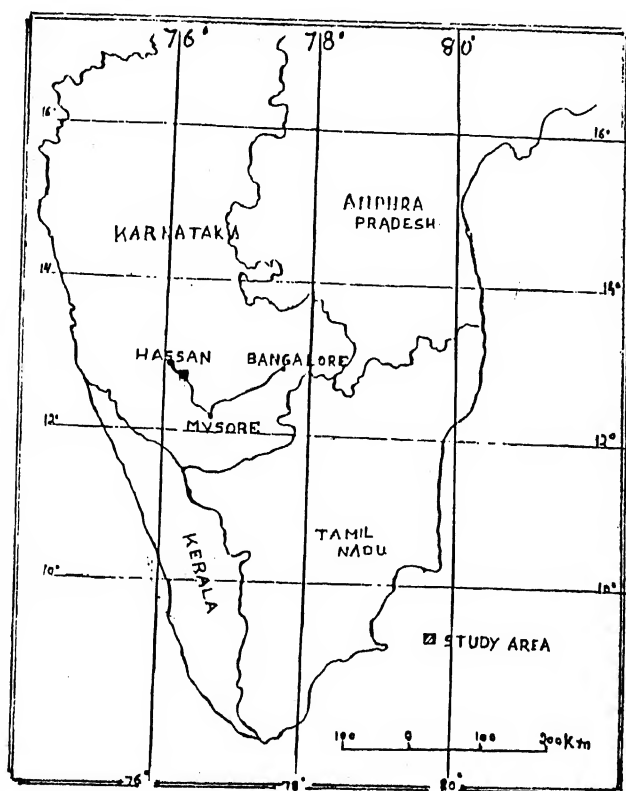

Figure 1. Location map of Mosale Hosahalli.

Figure 2. Left lateral view of vertebra. ce, centrum; di, diapophysis; n. sp, neural spine; pr. zy, pre zygapophysis; pt.zy, post zygapophysis; ve.c.c., vertebrocostal canal.

carried by water currents to the place from where it was collected.

The country rock of the area is peninsular gneiss enclosing schistose rocks of

Figure 3. Anterior view of vertebra. ce, centrum; ex, extraneous part; hy, hypapophysis; n.a., neural arch; n.c., neural canal; n.sp., neural spine; pa, parapophysis; pr.zy, pre zygapophysis; ve.c.c., vertebrocostal canal.

Bababudan group, Dharwar Supergroup spanning an age of 2600 to 3000 m.y. in the Archean¹. These rocks are highly metamorphosed and are commonly devoid of any fossil remains^{1,2}. This brief geological account covers a general

Figure 4. Posterior view of vertebra. ce, centrum; ex, extraneous part; hy, hypapophysis; n.a., neural arch; n.c., neural canal; n.sp, neural spine; pa, parapophysis; pt.zy, post zygapophysis; ve.c.c., vertebrocostal canal.

Figure 5. Left lateral view of vertebra.

study of the entire Bababudan group as a whole which also includes Mosale Hosahalli from where the collection of our material was made. The soil of the area is grey in colour and contains clay and mica particles. Kankar nodules are abundant below this mantle of soil.

The vertebra measures a length of 9 cm, height of 14 cm and width (in the region of zygapophyses) of 9 cm. The material is cement grey in colour and weighs about 670 g, which is quite heavy when compared to the modern crocodilian vertebra, which is pale yellow in colour and relatively lighter also.

Figure 6. Anterior view of vertebra.

Figure 7. Posterior view of vertebra.

The vertebra shows the centrum, neural arch and accessory structures. The centrum is procoelous, being broad and low anteriorly and narrow and high posteriorly. Dorsolaterally it bears a pair of vertebrocostal canals for the passage vertebral arteries. The diapophyses have been partly preserved. Feeble traces of hypapophysis and parapophyses are also seen.

The neural spine arises as a dorsal median vertical ridge from the neural

Figure 8. Dorsal view of fibula. ar.f.1, facet for articulation with astragalus; ar.f.2, facet for articulation with calcaneum; sh., shaft.

Figure 9. Ventral view of fibula. ar.f.1, facet for articulation with astragalus; ar.f.2, facet for articulation with calcaneum; sh, shaft.

arch. The zygapophyses extend as lateral flattened horizontal processes from the sides of the neural arch. The pre- and post-zygapophysis have broad and shallow articulating facets³ (Figures 2-7).

Figure 10. Dorsal view of fibula.

Figure 11. Ventral view of fibula.

In view of the above details regarding the fossil vertebra, the same has been identified as a cervical vertebra of the order, Crocodilia. However, there is an extraneous part attached to the zygapophyses on the right side of the vertebra, whose identity and presence are not clear.

From the above description, it is clear that our material is distinctly different from the corresponding modern crocodilian vertebra.

In the fibula the length of the shaft measures 12 cm and its diameter is 3 cm. The articulating surface of the distal end has a diameter of 5.5 cm. The material is cement grey in colour and weighs 250 g which is quite heavy when compared to the corresponding fragment of modern crocodilian fibula.

The fossil bone shows a thick shaft and a terminal expanded portion showing a central shallow depression and articulating surfaces. It also shows a conical process posteriorly.

The above remains are probably the distal part of fibula of the order Crocodilia. Probably the proximal two-thirds of the bone is wanting⁴.

The fibula articulates with the tarsus at its distal end. In the living crocodile, there are two proximal tarsal elements articulating with tibia and fibula. These are the astragalus and calcaneum. Fibula articulates with the astragalus at its inner articulating surface and with the calcaneum at its outer articulating surface at the region of bony projection (Figures 8–11).

From the study of the crocodilian 'fossil' vertebra and fibula, it seems that a very small area of sedimentary fos-

siliferous rocks is lying over the non-fossiliferous schistose rocks which cover most of the area.

This is the first report of the occurrence of crocodilian 'fossil' skeletal remains from this place which incidentally gets the name Mosale Hosahalli. The term Mosale in Kannada means a crocodile. Perhaps, because of occurrence of crocodiles in this place in the distant past in a large body of water, probably a river, the village might have obtained its current name, Mosale Hosahalli.

There are reports of similar 'fossils' being found in the late Pleistocene gravel beds of peninsular Indian rivers (Ashok Sahni, pers. commun. 1995).

ACKNOWLEDGEMENTS. We are indebted to Prof. Ashok Sahni, Director, Centre of Advanced Study in Geology, Panjab University, Chandigarh for his invaluable help in identification of the 'fossil' material and his encouragement. Thanks are also due to Sri M. S. Shivashankar, Geologist, Department of Mines and Geology, Government of Karnataka, Hassan for helping us in furnishing the details pertaining to the geological aspects of the locality from where the specimen was collected. We are grateful to Dr T. V. Shivarudrappa, Retired Professor, Department of Geology, University of Mysore, Mysore, for his help in identifying the material as a fossil. Our thanks are also due to Mr Dayananda Prasad of Banavasi Village, Hassan Taluk for his help in bringing to our notice about the existence of fossil material and collecting the same for our study.

Agnostid trilobites from the Cambrian Sequence of Zanskar and their stratigraphic significance

The Zanskar area forms a vast mountainous region between the great Himalayan range in the south-west and Indus Valley in the north-east and occupies the southern part of Zanskar region lying between lat. 30°00–33°08'N and long. 77°15' to 77°25'E (Figure 1). Srikantia *et al.*¹ have given a detailed geological map of the Zanskar region. Gaetani *et al.*² also discussed the significant stratigraphy and sedimentology of the Zanskar. Dungrakoti *et al.*³ also recorded trilobites from Zanskar Valley and assigned an upper Cambrian–Ordovician age. Whittington⁴ described some trilobites from Kurgiakh section of the area. Nanda and Singh⁵ worked on the sedimentology¹ of the area. Since Zanskar Basin shows continuity with the Spiti Basin, the lithostratigraphic nomenclature adopted here

is identical to the one adopted for Spiti Basin. A complete succession of Palaeozoic–Mesozoic rocks is exposed along the right bank of Zanskar river in the Lingti valley (Figure 1). Rocks of Cambrian to Permian age exposed in the Valley are rich in fossils. The sequence in the southwestern part of Zanskar is represented by Giambal, Haimanta and Kanawar groups. In Kurgiakh valley the rock formations found at the base belong to the Batal Formation and Kunzam La Formation of Haimanta Group, consisting of greyish or greenish micaceous schists which attain a huge thickness. The upper Kunzam La Formation according to Hayden⁶ corresponds to the Parahio 'series' of Spiti from where Middle Cambrian trilobites have been recorded. The Haimanta

group of the Zanskar is overlain by the Kanawar Group which is divided into three formations, namely Lipak, Po and Ganmachidam formations. Kanawar Group directly overlaps the Thango Formation in most of the Zanskar Basin.

The fossiliferous Cambrian sequence in this valley has a faulted contact with Gumbranj Granite. A diversified trilobite fauna was collected from this sequence. The fauna signifies a Middle Cambrian age. The lowermost bed of this sequence consists of a laminated micaceous shale chiefly attaining a great thickness and is devoid of fossils. Gaetani *et al.*² grouped this shale under Phe Formation of Precambrian to Early Cambrian age.

The trilobite fauna obtained from this area include the following taxa.

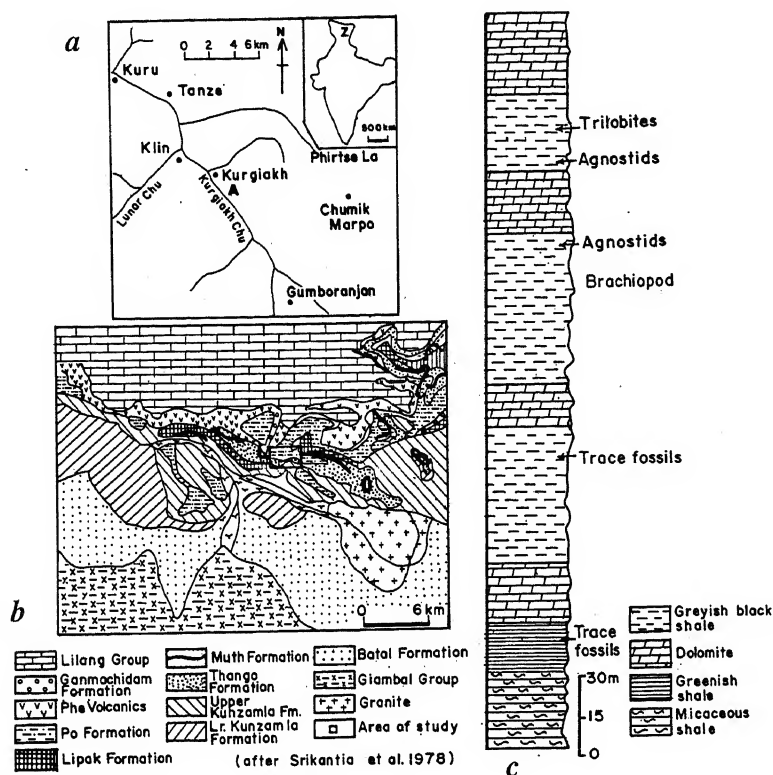

Figure 1. a, Location map of Zaskar area showing Kurgiakh section; b, Geological map showing the area studied (After Srikantia *et al.*¹); c, Stratigraphic column.

Repository. The fossils have been deposited in the Palaeontology Museum, Geology Department, Jammu University. Fossil specimen numbers are indicated for each taxa after the figure number in the explanation to Figure 2.

Acadagnostus scutalis, Salter, 1886 (Figure 2: 1, 2, 5).

The specimens correspond with *Acadagnostus scutalis* in its evenly curved cephalon and pygidium and well preserved axial pygidial node. The specimens differ from *Hypagnostus cf. clipcus* in the absence of subquadrate pygidium, short axis and width being greater than length.

Peronopsis tramitis, Opik, 1979 (Figure 2: 8, 9, 10, 21).

The specimens resemble *Peronopsis tramitis* in a number of morphological characters such as subcircular cephalon, small and circular frontal glabellar

lobe, well-preserved pygidial axial node. They differ from *Peronopsis rakuroensis* Kobayashi in the shape of the cephalon and strong median glabellar node.

Peronopsis cf. longinqua Opik, 1979 (Figure 2: 7, 11, 17).

The specimens differ from *P. prolixa* in the shape of the posterolateral spines. They also differ from *P. (Itagnostus) elkedraensis* in the shape of the glabella and presence of small node on the anterior glabellar lobe. The form is known to have three lobes in the axial region which is not clear in the present specimens and hence they are tentatively referred to this species on the basis of subrounded cephalon, presence of prominent pygidial axial node and its placement.

Peronopsis (Itagnostus) cf. elkedraensis (Etheridge Jr.) Opik, 1979 (Figure 2: 14, 16, 19).

The specimens are comparable with *P. (Itagnostus) elkedraensis* because of the angularity at the anterolateral cephalic margins, absence of preglabellar furrow, position of the pygidial node and subrounded shape of the pygidial marginal furrow. The specimens differ from *P. montis* Mathew in the presence of the glabellar node and absence of posterolateral angularity of the pygidial rim.

Peronopsis sp. (Figure 2: 22, 24, 25).

The specimens contain a number of pygidial and cephalic characters of that of the genus *Peronopsis*, such as nearly circular cephalon with parallel acrolobes, glabella divided by a transglabellar furrow, in the ratio of 2:3, pygidium semicircular to rectangular shaped, pygidial axis gently narrowing posteriorly, etc. Because of their poor preservation they have been identified only up to generic level.

Peronopsis amplexa Robison, 1982 (Figure 2: 3, 4, 6, 13).

The specimens correspond to *P. amplexa* in the cephalic and pygidial characters especially in their smaller average size, wide axial lobes, weak segmentation in the pygidial axis and in the absence of marginal spines. Robison⁷ has discussed in detail the comparative morphology of *P. amplexa*.

Diplagnostus floralis Opik, 1979 (Figure 2: 18, 23).

The specimens compare with *Diplagnostus floralis* on the basis of wide pygidial axis at the anterior side and abruptly pointed rear side, rapid widening of the marginal furrow and two faintly-preserved furrows dividing the pygidium into three lobes.

Doryagnostus magister Whitehouse, 1936 (Figure 2: 12, 15, 20).

The specimens resemble *Doryagnostus magister* in a number of physical characters such as dimensions of cephalon nearly equal to the pygidium, width of the pygidium which is more than its length, curved nature of pygidial spines, etc. The specimens also show resemblance with *Doryagnostus incertus* but can be differentiated on the basis of the curved nature of marginal spines. The specimens can also be differentiated from *D. natalibrae* in the absence of scrabicles over the surface of the acrolobes and bow-shaped transglabellar furrow.

Figure 2. *Acadagnostus scutalis*: 1 \times 8.4 (KUF-706), 2 \times 9.7 (KUF-704), 5 \times 9.7 (KUF-720). *Peronopsis tramitis*: 8 \times 10.1 (KUF-702), 9 \times 8.1 (KUF-714), 10 \times 8.3 (KUF-721), 21 \times 12.8 (KUF-706). *Peronopsis cf. longinqua*: 7 \times 5.5 (KUF-705), 11 \times 13.6 (KUF-723), 17 \times 10.5 (KUF-469). *P. (Itagnostus) cf. elkedraensis*: 14 \times 7.4 (KUF-707), 16 \times 11.2 (KUF-699), 19 \times 15.0 (KUF-716), 26 \times 10.8 (KUF-728). *Peronopsis* sp.: 22 \times 11.1 (KUF-714), 24 \times 12.1 (KUF-705), 25 \times 14.5 (KUF-718). *P. amplaxa*: 3 \times 11.7 (KUF-724), 4 \times 9.3 (KUF-705), 6 \times 11.7 (KUF-703), 13 \times 8.4 (KUF-728). *Diplagnostus floralis*: 18 \times 23.5 (KUF-723), 23 \times 10.3 (KUF-728). *Doryagnostus magister*: 12 \times 18.2 (KUF-710), 15 \times 13.8 (KUF-716), 20 \times 10.4 (KUF-708). The specimen numbers are given in parenthesis.

SCIENTIFIC CORRESPONDENCE

The agnostid fauna from the Middle Cambrian of Zaskar is closely comparable with that of the adjoining basins of Kashmir and Spiti. In Kashmir the agnostids consisting of different species have been described from *Solenopleura-Tonkinella* zone of Middle Cambrian⁸. Agnostids from Zaskar are also comparable with the assemblage recorded from *Ptychognostus gibbus* zone of Middle Cambrian in Australia⁹ and with the same zone in North America¹⁰. The Agnostid fauna presently described and other polymerid fauna indicate a shallow marine condition of deposition.

Gas emanations and subterranean sounds/microearthquakes in Marathwada, Maharashtra, India

After the great devastating earthquake of Killari on 30 September 1993, the Marathwada region is again experiencing microearthquake activity. This microearthquake activity is also accompanied by subterranean sounds and gas emanations. Earthquakes are many times accompanied by gas eruptions at high pressure. When this gas at high pressure comes out from small pores or fractures, it makes sharp sound which includes rushing sound¹. The Killari region of Latur district has received two tremors on 29 August 1996, at 12.10 am and 12.30 am and two tremors on 2 September 1996, at 1.30 am and 1.52 am. These tremors were of magnitude 4 (*Lokmat* newspaper dated 29 September, 1996). These tremors were followed by gas emanations at Poharegaon 29 km NW of Latur and at Gunj 35 km NW of Nanded (Figure 1). Subterranean sounds were also heard in Poharegaon.

A week following the earthquake tremors received on 29 August 1996, there is report of gas emanations and it continued for a few days. At Poharegaon, gas emanations started on 6 September 1996 and continued till 12 September 1996 while at Gunj emanations started on 7 September 1996, and continued till 9 September 1996. The description of the sites is as follows:

Site 1 Poharegaon (Taluka Renapur, District Latur): The site of gas emanation is about 2 km NW of Poharegaon.

Gas emanations were first felt by animals and they turned their way because of the hissing sound. Then villagers reported an odourless emission coming out up to 1 ft height from small pores of

0.5 cm diameter in an area of about 0.5 m diameter. The pores were observed only on the upper 4 inches of soil cover (Figure 2 a). The hissing sound could be heard up to the distance of 125 feet. After closing one hole, a

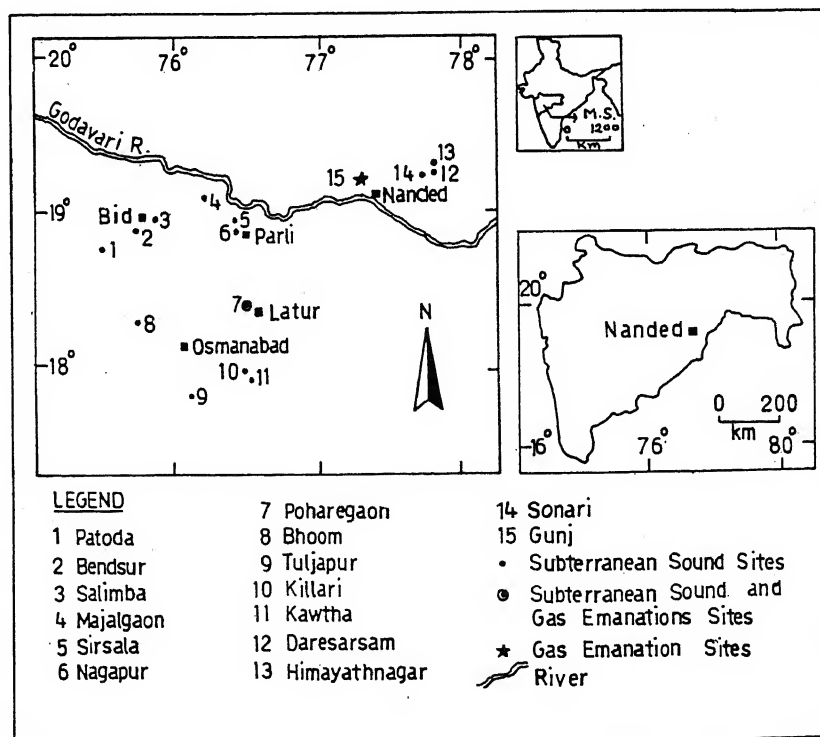

Figure 1. Location map of the sites.

Figure 2. *a*, Gas bubbling out (Poharegaon); *b*, Small hole through which gas blew out (Gunj). Note that villagers have excavated the soil up to 2 ft to find out the source of gas emanation; *c*, Water clogging near the site of gas emanation (Gunj).

new one used to open up and after pouring water on these holes, water showers were thrown into air up to the height of 1/2 ft. Subterranean sounds are also reported.

The gas emanations occurred after the region had received heavy rains. After the earthquake of 30 September 1993 also,

gas emanations had occurred just after the Latur region received heavy rains².

When our team visited the site, water clogging was observed just by the side of the gas emanation site, and gas emanations had almost subsided. Gas was seen to bubble out only when water was poured on these holes. Termites were

reported to be coming out during emanation. The temperature recorded in the holes from which gas was coming out appeared to be normal. It was 27.5°C and there is no report of ground heating during gas emanations.

Site 2 Gunj (Taluka Vasmat, District Parbhani): The site of gas emanation is about 1 km south of Gunj. The river Ahana which follows the lineament trending N60W–S60E is on one side of the gas emanation site and a small stream which also follows a minor lineament trending E–W is on the other side of the gas emanation site. There is no effect of microearthquake in this village but gas emanations are reported. Subterranean sounds are not reported from this village. The gas is reported to be odourless and temperature was also normal. The area is not reported to have become hot. Gas emanation was only through one hole of diameter 1 cm (Figure 2*b*). Water clogging was observed just by the side of the gas emanation site (Figure 2*c*). Termites were reported to be coming out during emanation. Though the gas is reported to be odourless, it is reported that a person who came in contact with the gas had swelling on his hand and face and felt irritation and a burning sensation. The site could not be visited during gas emanation and hence no samples of gas were collected.

Site 1: Poharegaon area is covered by basaltic lava flows. A basaltic flow consist of two units – a lower massive and compact basalt and upper vesicular or amygdaloidal zeolitic basalt. The massive basalt is dense, dark grey to black, fine grained with only few large vesicles. Amygdaloidal basalt is brown to greenish with almost all vesicles filled with secondary mineral zeolites³.

Amygdaloidal basalt occurs towards SE side of the gas emanation site and compact basalt towards NW side. Gas emanation had occurred at the contact of these two rock types. Amygdaloidal basalt is slightly tuffaceous and highly weathered and fractured and can be broken into pieces even after applying a little pressure by fingers. The soil thickness over this rock type is about 25 ft. This rock obviously shows more porosity and is a good potential zone for groundwater. Dug wells present in this rock have ample amount of water even during summer. A vertical borehole of 50 ft depth taken in a dug well showed

Figure 3. Explanatory diagram for the gas emanations sites (not to the scale).

fast rate of drilling and yielded good amount of water. No rock particles came out of the bore and all the material was lost in the cavities or fractures present in the highly-weathered basalt. Soil cover over compact basalt is about 60 ft. Borewell of 140 ft depth taken in the adjacent rock did not yield water (Figure 3 a).

Site 2: Gunj area is also covered by basaltic lava flows⁴. A basaltic flow consists of two units – a lower massive and compact basalt and an upper vesicular or amygdaloidal tuffaceous basalt. The massive basalt is dense, dark grey to black, fine grained. Amygdaloidal basalt is pinkish to reddish and contains brown volcanic glass⁴. At the site of gas emanations, soil thickness is about 35 ft, below which weathered and fractured amygdaloidal basalt is present. Below amygdaloidal basalt, compact basalt is present which is devoid of fractures. Groundwater occurrence is reported only from the weathered amygdaloidal basalt which is acting as a reservoir rock (Figure 3 b).

Sites of subterranean sounds/microearthquakes and ground cracks which are noticed in Marathwada region for about a month now include Daresarsam, Bhoom, Salimba, Killari and Latur which were also reported to have suffered earlier from these types of activities in 1993 (ref. 2).

The following is the description of the sites where subterranean sounds/cracks are reported in Marathwada re-

gion for the last one month (Source: Daily newspaper *Lokmat*, *Samana*, National TV, News and Civic authorities).

1. Patoda, Bid district: From 10 to 17 September 1996 explosion-like sounds were heard (Source: Good Morning India National TV News, 18 September 1996).

2. Bendsur, Bid district: From 21 to 23 September 1996, explosion-like sounds were heard. A ground crack at the foothills was also reported.

3. Salimba and Majalgaon, Bid district: From the last few days, subterranean sounds were heard.

4. Sirsala, Bid district: A ground crack of 20 ft in length was reported from this village.

5. Nayagaon, Bid district: A ground crack 150 ft in length and 1 ft in width is reported.

6. Nagapur, Parli taluka, Bid district: From 21 to 24 September, subterranean rumbling sounds were heard.

7. Van, Parli taluka, Bid district: For the last few days subterranean sounds have been reported. Dam wall crack of about 1 km in length is reported to have a width of 1 inch and depth of about 2½ feet. Chandrashekhar, Senior Geologist, GSDA has visited the place.

8. Poharegaon, Renapur taluka, Latur district: On 28 and 29 September 1996, rumbling sounds are reported from this village. It is reported that sounds travelled from east to west. A small tremor is also felt.

9. Latur: On 14 September 1996, fire cracking sound from a well was reported to be coming out. The well was dry during summer. After heavy rains it received water and was followed by subterranean sounds.

10. Bhoom, Osmanabad district: On 21 September 1996, thundering sounds were reported, and after the sounds some houses received minor cracks and 10–12 small pits developed in this region.

11. Tuljapur, Osmanabad district: On 21 September 1996, loud subterranean sounds were heard which were followed by shattering of tin sheds and small shaking was also felt. Abnormal behaviour of pet animals was also reported.

12. Killari, Latur district: On 28 September 1996, cloud thundering-like sound was heard which travelled from east to west. A tremor was felt for 4 seconds and shattering of sheds (tin and asbestos) was reported. Similarly, adjoining villages Gangapur and Ausa in Latur district experienced a small tremor. This tremor has caused cracks and peeling of plasters from the rehabilitated houses in Killari Tanda.

13. Kawtha, Umarga taluka, Latur district: On 17 and 18 September 1996, subterranean sound was reported to be coming out from the ground nearer to the site where a 2 × 2 feet depression developed after the tremor.

14. Sonari, Himayatnagar and Daresarsam, Nanded district: From 14 to 17 September 1996, explosion-like subterranean sounds were reported. After the sounds, shattering of sheds, peeling of plaster from walls and falling down of utensils from shelves were reported.

Marathwada region is experiencing microearthquake activity, accompanied by gas emanations and subterranean sounds. Earlier also there were reports of subterranean sounds and gas/steam emanations and microearthquake activity about two months prior to 30 September 1993 earthquake⁵. Gas emanations have been reported just after the earthquake on 29 August 1996 and 2 September 1996 after the region received heavy rains. Amygdaloidal basalt in this region is highly weathered and fractured and fast drilling rate and loss of material in borewell itself suggests presence of cavities and is probably the site for trapped gases. Heavy rain has resulted in the water table rising and

saturation of the region with groundwater. This might have enhanced the gas eruption. The earthquake tremors received recently might have opened up the fractures and in all probability gas emanations are due to release of trapped gases in amygdaloidal basalt as a result of a microearthquake. In both the cases of gas emanation, no fractures were observed on the surface. There is probably a change in fracture porosity of the weathered and fractured basalt flows present at deeper or shallow levels caused by the tremor shaking⁶. Gases were coming out from small pores. Termites were also reported to be coming out during emanation and both the sites were small mounds in nature. The rise in water table might have displaced the entrapped air that would find its way up through termite burrow holes which have acted as gas outlets. It is to be noted here that near the gas emanation sites, water clogging is observed. In the absence of radon and

helium analysis, it is difficult to link these gas emanations to deep origin and it is preliminarily guessed that gas emanations at these sites are related to escape of trapped air in fractured basalt from a shallow level. The burning sensation experienced by the person might be explained by the release of injurious gas from the decay of biomass which is used in the field as fertilizers.

Uranium mineralization in the Palnad sub-basin, Cuddapah Basin, Andhra Pradesh, India

Recent investigations by Atomic Minerals Division have brought into focus the presence of uranium mineralization hosted in fracture zones in granite close to the unconformity with the overlying Srisailem quartzite in Lambapur area^{1,2}, in the north-eastern part of the Cuddapah basin. Investigations further east of the Srisailem sub-basin have revealed the presence of significant concentration of uranium (up to 0.55% U_3O_8 with negligible ThO_2) in the quartzite grouped under Banganapalle Formation of Kurnool Group. This radioactive quartzite is exposed in the western parts of the Palnad sub-basin near Koppunuru, Alugurajupalle and Dwarakapuri villages (Survey of India Toposheet No. 56 P/7; 16°24'0"N; 79°20'20"E), Guntur district, Andhra Pradesh. Petrographically, the host rock is quartz arenite (orthoquartzite) with a high degree of mineralogical and textural maturity. Preliminary field data indicates that the mineralization has been influenced by major faults/fractures which facilitated the migration of (hydrothermal?) mineralizing fluids.

The main uranium-bearing minerals in this rock are pitchblende, coffinite, phosphouranylite and metazeunerite associated with sulphides of copper, lead and iron. An attempt is made in this note to bring out the salient features of this new uranium find in the Palnad sub-basin, which has

enhanced the uranium potentiality of the northern parts of the Cuddapah basin.

The Banganapalle quartzite is the oldest lithounit of the Palnad sub-basin (equivalent to Kurnool sub-basin) in the north-eastern corner of the crescent-shaped Cuddapah basin³. In this part of

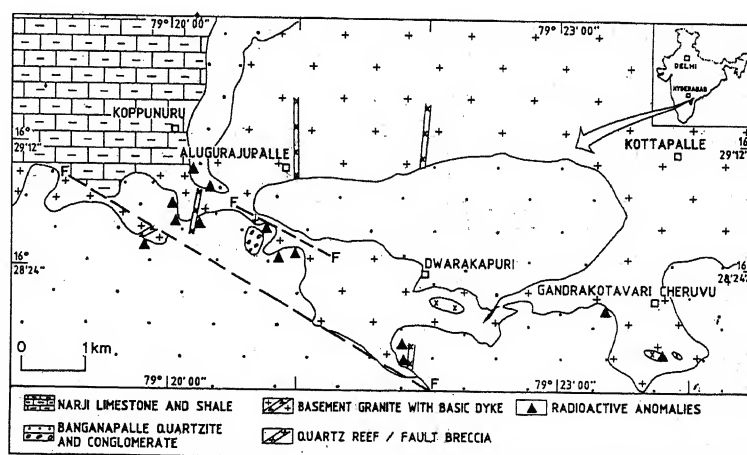

Figure 1. Geological map of Koppunuru–Dwarakapuri area.

SCIENTIFIC CORRESPONDENCE

the Cuddapah basin, the Banganapalle quartzite unconformably overlies the basement granite (Figure 1). The basal unit of this formation is a conglomerate/pebbly quartzite, followed by ferruginous and grey quartzite exhibiting primary sedimentary structures such as ripple marks and current bedding. These are invariably capped by pitted quartzite. At places, this quartzite has intercalations of black shale. Euhedral pyrite and specks of chalcopyrite occur throughout this sequence. The quartzite is subhorizontal with a low dip of 2° to 6° towards southeast. Major WNW-ESE trending faults, besides NNE-SSW trending minor faults, are the major structural features of this area and are marked by fault breccia, fault scarp and quartz reefs.

The preliminary petrographic studies on the samples suggest that the host rock is quartz arenite (orthoquartzite), which is well sorted, with subrounded to rounded, fine to medium-sized, grains of monocrystalline quartz, cemented by authigenic silica. In a few samples, lithic fragments of granite-mylonite, glauconite, chlorite, opaques and carbonaceous matter are present (8–20% modal). The rock fragments of crushed granite indicate granitic provenance.

The presence of glauconite, with traces of carbonaceous matter, indicate marginal marine, mildly alkaline and reducing environment of deposition. The high degree of mineralogical and textural maturity and the chemical data of major oxides (analysed by rapid method of analysis using spectrophotometry, atomic absorption spectrometry, volumetry and flame emission photometry techniques) (Table 1) point to a stable erosional cycle of granitic provenance.

Uranium mineralization has been recorded in the grey and ferruginous quartzite of Banganapalle Formation and the quartz reef in basement granite. Mineralization occurs in several patches (Koppunuru – 20 m × 25 m to 150 m × 20 m, Alugurajupalle – 200 m × 1–5 (thickness), Dwarakapuri West – 300 m × 5 m (thickness) to 100 m × 2 m (thickness) and Dwarakapuri South – 400 m × 100 m) in a roughly E–W trending linear belt of 8 km, bounded on the southern side by a major fault (Figure 1). Uranium concentration, in the quartzite ranges from 0.013 to 0.55% U₃O₈ (Table 2) and the maximum concentration is observed at Dwarakapuri. Preliminary petrographic and X-ray diffraction studies indicate that the uranium mineralization is mainly at-

tributed to the primary uranium minerals – pitchblende (UO₂ · UO₃) and coffinite (U(SiO₄)_{1-x}(OH)_{4x}), the secondary uranium minerals – uranophane (Ca(UO₂)₂(SiO₃OH)₂ · 5H₂O), phosphouranylite (Ca(UO₂)₃(PO₄)₂(OH)₂ · 6H₂O) and metazeunerite (Cu(UO₂)₂(AsO₄)₂ · 8H₂O) and the accessory uranium minerals – chevkinite (Ca, Ce)₄(Fe Mg)₂(Ti, Fe)₃Si₄O₂₂) and zircon (ZrSiO₄). These are associated with chalcopyrite (CuFeS₂), pyrite (FeS₂) and galena (PbS). The uranium-bearing minerals occur along fractures, cavities and bedding planes. Some amount of uranium is also adsorbed on goethite, glauconite, clays, goethitized pyrite, carbonaceous matter and malachite. Interestingly the quartz reef, with associated chalcopyrite and pyrite analysed up to 0.036% U₃O₈.

The radiometric assay values indicate that most of the samples show disequilibrium in favour of parent (uranium). The disequilibrium ratio, on an average, is 1:1.35. This high disequilibrium in favour of uranium is apparently related to the high concentration of secondary uranium minerals in these quartzites.

In view of the favourable geological setting, similar to that of Lambapur^{1,2} the presence of high concentration of

MEETINGS/SYMPOSIA/SEMINARS

National Symposium on Natural Resources Management System

Date: 26-28 February 1997

Place: Tiruchirapalli

Themes include: Water-surface/ground, land use patterns, Biodiversity - Flora and Fauna - diversity, endemism, endangered species, conservation, aquaculture augmentation strategies, Human resources - Indigenous knowledge, ethnobotany, Forest and Wasteland management, Socio-political issues in conservation, Toxicology - radiation, biocides, xenobiotics, Marine bioresources, Geography, mineral resources, remote sensing and GIS, Biotechnology and resource management, Sustainable development of natural resources.

Contact: Dr S. John Britto, Convenor
National Symposium on Natural Resources Management System,
Department of Botany, St. Joseph's College

Science education in Indian universities: Proposal for a 5-year integrated M Sc course in life science

Sohan P. Modak

The undergraduate and postgraduate science degree courses in India lack a conceptual basis and systems approach for designing syllabi. Existing syllabi are repetitive and wasteful. An integrated 5-year M Sc in life sciences is proposed. Life sciences decipher mechanisms and processes underlying structural and functional organization and the basis of instability of the living state. These should be taught in a synthetic sequence beginning with Physics, Chemistry and with English, Computing, Mathematics and Statistics as languages during the first 3 years. The final two years should cover subject of specialization and advanced streams with a research base and management skills. Summer training and remedial courses should be obligatory.

THOUGH India is the tenth largest world economy with the third largest trained work-force in science and technology, it is still a developing country. The size of our economy primarily reflects the developments in the agriculture and the size of our population, and only secondarily the size of our industry that mostly caters to the local needs. We do not really design, develop and produce modern amenities maintaining high quality standards using our trained work-force. Barring specific cases like rockets, satellites, or a small software industry, our industrial missions involve outdated ckd kit assemblage or copying through reverse engineering. Post-war Japan, on the other hand, with practically no natural resources, started out from scratch, but where is it now? Mountain ice is the only natural resource of Switzerland¹ and yet it produces the best of everything from textiles to paper, machine tools to industrial plants, watches to microelectronics, marine engines to solar cars, etc. Its agriculture can hardly feed 60% of its population, yet the food processing giant, Nestlé, is Swiss. For a 41,293 sq km landmass and a population of about 6.8 million, Switzerland boasts of one of the largest pharmaceutical industry with CIBA-Geigy-Sandoz combine and Hoffmann-La Roche. In contrast, India has immense natural resources, practically a mosaic of all climates and biodiversities, but do we have any impact on the global trade and economy? Nation building and technological leadership require trained work-force with creative and innovative mind sets, hard work and entrepreneurship. This is what the education system should catalyse. Therefore, it is necessary to assess our educational system and its output.

The NCERT and the State Board of Higher Education devise and regulate the teaching syllabi and method-

ologies up to the 10+2 level. NCERT has maintained the tempo for a continuous evolution of syllabi to ensure a broad-based training. In contrast, an excessive specialization in college and university, without emphasizing the basic tenets of science education has led to the production of a work-force loaded with information but without integration. This situation is similar to our copying data bases with neither relevant questions to ask nor the tools to find answers. In Maharashtra, mathematics has been de-emphasized *de facto* for +2 level students opting for the biology stream. The 10+2 acts as a screen to select the 91%+ students seeking admission to medicine, engineering and technology courses. Earlier, it was respectable to study sciences and a good proportion of students around $80 \pm 5\%$ entered the science discipline. With the proliferation of private engineering and medical colleges, the screen for open seats has moved down drastically. Similarly, with the advent of professional courses such as MBA attracting better informed and versatile students, only those from the lower percentile are available for traditional M Sc. Ten years ago, admission to physics and electronics courses at the University of Pune ended at 75% marks, while today this is down to 50%. In some subjects moreover, over 60% seats have remained vacant at FY B Sc and the enrolment to M Sc will continue to decrease. Since 10 years there has been a diminishing interest in Sciences world wide and we are just beginning to see the fall-out in India. A major proportion of Indian M Sc degree holders become teachers for lack of better opportunities. Among them, less than 7% students pass the UGC-CSIR NET because of the poor quality of B Sc and M Sc training. In India we have over 200 universities and 10,000 colleges whose job is to produce trained personnel. The present education is neither learner-friendly nor user-friendly, nor has it kept pace with modern trends in sciences. Besides, most bright students joining Medicine

Sohan P. Modak is in the Departments of Zoology and Botany, University of Pune, Pune 411 007, India.

and Engineering, do not go in for research and development. Let us examine all components of our science education.

To implement undergraduate and postgraduate syllabi, institutions and government provide the infrastructure. Let us examine their performance. The Boards of Studies continually dilute syllabi, ignore modern teaching methodologies, and promote obsolete and often-plagiarized teaching texts. Course structure and teaching sequence are haphazard with futile attempts to introduce 'catchy' titles under the garb of vocational courses which the teachers are not competent to teach. The laboratory exercises are obsolete, unimaginative and lack the inductive stimulus. Most postgraduate departments follow this trend. A few try to undo the damage by packaging so much material that it is difficult to digest. Either situation leads to a perpetuation of mediocrity, absence of work culture, suppression of dissent, kills curiosity, and wastes student's time, thereby preventing development of scientific temper. Boards of Studies also promote mediocre and repetitive Ph D theses supervised by guides of questionable competence and assessed by referees of equally questionable integrity. Managements are responsible for this lack of infrastructure and operate the educational institutions as money-spinners through capitation fees and forced donations. Elected Governments are the main culprits in giving higher education the lowest priority. Furthermore, many teachers participate in a parallel 'black' educational network, thriving on private coaching classes and tuitions while disregarding their professional obligations in the classroom and laboratory. Governments engage only in the rhetoric of a mass higher education and not higher education *per se*. The UGC, the body for regulating the quality of higher education, is toothless. Attempts to make passing in NET/SET compulsory for teacher appointments have failed under the pressure of various teachers' unions. All of this has led to a monumental 'academic fraud' perpetrated on the Indian student and the nation.

By mid-80s it became clear that a dramatic fix was necessary to make a quantum improvement in the teaching infrastructure and syllabi in modern biology. The National BioTechnology Board mooted the idea of introducing a training programme in M Sc biotechnology with UGC's support. For this course, science graduates were selected by an entrance test. The programme, originally restricted to 6 universities, quickly became a model for quality training in Life Sciences as it included many innovations, flexibility in its course-design and the openings for creative teaching. The programme attracted good students in the 80 ± 5 percentile. However, the geopolitical considerations led DBT and UGC to extend this programme to over 19 institutions. Consequently, the percentiles dropped below 75%, and the syllabus- and teacher-quality plummeted. Ever-changing policies on reservations for teaching posts and

lack of concept-basis have drastically reduced the effectiveness of biotechnology training programmes. For example, in Pune 3 out of 6 teaching posts still remain unfilled. This is also true of other subjects which suits state exchequers who naturally save on already depleted funding for higher education. Almost everywhere in India, a new class of education empire-builders have come to the fore who have done very little to evolve a good educational system. I agree with Sitaramam² that the Biotechnology students do well because they are basically talented and not necessarily due to skilled teachers, good syllabi on job-potential. In mid-eighties, UGC and CSIR introduced the National Eligibility Test (NET) for postgraduate research fellowships and evolved advanced syllabi hoping that this would force major revisions in the undergraduate and postgraduate syllabi in the country. I was involved in the establishment and the syllabus-framing of both Biotechnology Training programme and the NET, but, in retrospect, I find that the impact of these syllabi on teaching life sciences in India is at best disappointing. Towards the end of 80s, various surveys revealed that, excepting for a few late-bloomers, most students performing around 80 percentile at +2 level do well in B Sc, M Sc and UGC-CSIR-NET. This has direct bearing on the learning potential of the student, communication skill of teachers, the quality of syllabi and infrastructure at the +3 level. As most students opt for undergraduate science subjects in the absence of other channels, the concern for a good teacher-quality has become important.

The teacher

A teacher is the primary medium of information-transfer who also catalyses the process of learning or integrating the information into knowledge. I examine here the requirements for making a good teacher. A good teacher should be motivated and able to communicate and induce the student. The teacher should be an expert who continually updates her/his knowledge. An ideal teacher should be highly skilled and involved in the process of enquiry and research. Such a teacher would have self-respect and the mind-set with scientific temper without loss of empathy. The teacher should know that the information is not knowledge and that creative teaching involves inductive inputs, not dictations, to promote learning. A good teacher also knows that the science is introvert. It superposes philosophy, and the process of creative learning involves analysis, synthesis, dissent, high-level curiosity, and the search for truth at any cost. These are the conditions for developing the scientific temper. In contrast, the technology is extrovert requiring skills and aptitude for execution, management, innovation and enterprise. On a ten-point assessment scale, I predict that the top 2% undergraduate teachers will

score 7 or more points, the next 5% five points and the remaining 3 or less. A horizontal scale-amplification with excellent, very good, good, fair and poor, will hardly change this situation. Using the same scale, postgraduate teachers in universities may perform only marginally better. Yet, student's examination scores are high because of manipulation of the examination system. This is the epitaph to undergraduate and postgraduate teaching in India and is the reason for a low-quality output of scientific work-force. Improving teacher-quality is not a make-shift operation possible through refresher courses and monetary incentives. It has to begin in the schools and colleges. Those who have not learnt, and therefore are not knowledgeable, just should not be in this profession. Learning is solving puzzles where a picture emerges using the memory base, recall, and integration in real-time by recognizing patterns through trial and error, multiple choice selection, common sense, general knowledge, intuition, creativity and enterprise.

The student

Then, what about a potentially good student? A good student should be able to read, write, speak and listen in the languages of science and able to observe, recognize shapes, patterns and relationships between these through recall and retrieval from the memory base. A good student should have acquired skills to analyse and synthesize, and be logical in thinking to question beliefs, falsities as well as truths. The student should be on constant lookout for what is happening around with fearlessness and hard work, should have manual skills to match the information base, appreciation of quality and quantity and the desire to overcome. Unfazed curiosity is the hallmark of a good student and the cumulative experience hones the sense of intuition and leads to creativity.

The goal of education is to facilitate an individual's passage to become an ideal student. He/she should be induced to develop a correct mind-set and personality conducive to the conduct of a scientific enquiry. 10+2 syllabi do not promote language skills, the mind-hand connection, fearlessness, general knowledge, appreciation of diversity and quantity, or thinking. At this point, the student is in a formative period, with the left side of the brain still untapped. Only serious attempts to promote each ideal trait will elicit a variable but positive response of the heterozygous *Homo sapiens* that cannot be achieved through a 'mutant' selection or despotic social engineering.

University of Pune – A case study

The University of Pune administers undergraduate and postgraduate education including professional degrees in engineering and medicine in three districts in Maharashtra, namely, Pune, Ahmednagar and Nasik cover-

ing over 200 colleges. The Boards of Studies (BOS) in each subject frame the undergraduate and postgraduate syllabi. Each BOS contains 6 members elected from among Heads of College Departments teaching TY B Sc, the Head of the University department, two teachers co-opted from among teachers who are not department-heads, and two outside experts. Thus the BOS primarily represents the constituency of undergraduate teachers and frames even postgraduate syllabi. Only after syllabus-ratification by the Academic Council, heavily representative of college teachers and managements, can the course be taught.

During 1980–1984, the University placed greater trust in teachers by allowing them to allot 40% marks by internal assessment for each course, and the entire examination of the so-called C component (vocational courses) and departmental courses. Unfortunately, this led to an excessive marking (never below 90%) in internal assessment and C component-courses very much due to peer-pressure and teacher's goofing-off, as compared to an average of 50% in centralized external examinations. The syllabus framing also included preparing question banks from which at least 50% of questions were included in the external examination. In most subjects the question banks were so small the teachers restricted their lectures to these, thereby diluting the syllabus and destroying the work-culture among students. Under the pretext of syllabus modernization, some of the important topics, taught in B Sc in 60s and 70s, were not covered till later in M Sc. The responsibility for this failed experiment lies squarely on the shoulders of the 'untrustworthy' teachers. This forced the University to eliminate question banks and the C component, and to change the marking ratio for external:internal from 60:40 to 80:20. The departmental courses still serve as fodder for teachers involved in excessive marking to cover-up their own deficiencies which is hardly different elsewhere.

In mid-80s, as the admissions to University PG courses, based on merit list at the +3 level did not reflect in the student performance in MA and M Sc, two solutions were used in science departments by preparing merit lists from marks secured in the external examinations and giving academic autonomy to University departments recipient of UGC–DSA, CAS and COSIST. Such departments framed their own syllabi and conducted entrance examinations independent of college postgraduate centres. In 1985–1986, NBTB (DST)–UGC awarded M Sc Biotechnology Training Programme to the Zoology department. Earlier, TIFR had initiated a collaborative teaching programme with the Physics department, while NCL did the same with the Chemistry department. UGC recommended that all departments with DSA, CAS or COSIST should have academic autonomy and admission through a nationally advertised entrance test. While admissions to Biotechnology and

Zoology continued through entrance tests, the latter with 25% seats to students with B Sc in other science subjects, the entrance tests in Chemistry and Physics were restricted to the collaborative programmes. As the number of PG centres in Zoology increased, the total number of seats for M Sc Zoology quadrupled. Admission to University department being in part on scores in the entrance tests, good but poor students in the rural areas became attracted towards the University department that does not charge capitation fee. Only in 1996 was the botany syllabus revised to match the standards of UGC-CSIR-NET, and an entrance test introduced. However, even this trend is not prevalent in most other universities. Unfortunately, the academic autonomy is now under fire from the University legislative bodies presumably due to the loss of control over University departments. Concomitantly, admissions to life science subjects at undergraduate level have dropped as the State Board of Higher Secondary Education separated biology and physical-mathematical science streams at +2. This drastically reduced the number of postgraduate centres with spurious teaching and examination record. Other than CAS-Sanskrit, UGC also identified statistics, sociology, and mathematics departments for special assistance. But these did not opt for an entrance test as the available seats remain unfilled using B Sc merit lists. In conclusion, the faculty performance in teaching and research should allow identification of expertise in the thrust areas in different subjects. Such an exercise in botany restricted the teaching to 5 specializations out of a plethora of eight.

Teaching life sciences in India

Life science subjects are taught at the undergraduate level in a macro to micro sequence beginning with, say, the animal kingdom, then the taxonomy, speciation, study of types, morphology, anatomy and histology. Cell biology, genetics and physiological chemistry are taught in the second and third years and the same of the first year is repeated, presumably at a higher level, without paying adequate attention to chemistry, physics, biochemistry and molecular biology. The pattern is repeated in M Sc, with minimal inputs in modern biology. This sequence inculcates an analytical frame of mind, destroys the ability to synthesize, to formulate concepts, designs, structures and to understand the structure-function relationships. The lack of a synthetic sequence also suppresses innovativeness, creativity and enterprise. This is true of all undergraduate and postgraduate courses in life sciences in India taught using substandard teaching methods which condemn students to the dungeon of boredom. Life science teaching has, thus, become sterile. An occasional flash of brilliance is a fluke due either to the inherent capacity of the student, or a

rare teacher, or both acting in harmony. Life sciences, though, offer a fertile field for research in chemistry, mathematics and physics, but in India, there is no dialogue among the teachers in these subjects. Thus, we will remain as customers for information from the West.

The correct approach

Life sciences decipher the mechanisms and processes underlying structural and functional organization of the living, and the basis of instability of components and systems, entities or beings, and their associations at molecular, cellular, and organismic levels. The principle of instability is evident in atomic nuclei and particles, atoms and their isotopes. At the molecular level, weak and strong interactions affect the stability of bonds. In contrast, most macromolecular aggregates hold together through weak interactions. These aggregates combine to form cell organelles and perform structure- and composition-specific functions segregated in space (position) and time. Cell organelles perform specific function and, in desired formulations, give rise to cells. Cell communities either share all functions, or exhibit complementarity through acquisition of specialized functions, and form organs like root, stem, leaves, flowers, fruit brain, heart, gut, bones, skin, etc. A perfect blend of structurally segregated but functionally linked cell communities give rise to multicellular beings that grow or reproduce, adapt to changes in the environment, defend against toxins and parasitic attack, and exhibit societal interactions. Only this sequence ensures assimilation of the paradigm relevant to the functionality and the division of labour. Thus, a student must begin learning in this 'synthetic' sequence for generating complexity out of simplicity which will have a dramatically different effect on the mind-set and temper as it follows an architect's and builder's 'psyche' based on constituents, composition and management. It favours inventiveness, allows trial-error and the ability to retrace the path, and completely changes the attitude of students towards life processes. We have attempted this approach in M Sc Zoology at Pune but it is often too late because college students already have hardened the opposite mind-set and lost the work-culture due to easy marks, weak and repetitive courses, poor teachers, absence of an argumentative atmosphere, and absence of modernity. Therefore, attempts to resurrect a correct teaching sequence at M Sc can be only fractionally successful. In India, more than a quarter million students lose three precious and intellectually formative undergraduate years. Earlier, a matriculate could become a clerk, section officer or a school teacher which the present-day graduate cannot. The present educational system is not only chaotic but dumps the students in the rut of postponing entry in to professional life.

What can we do?

We have to implement drastic changes in the system and process of higher education. The correct format includes (i) a synthetic teaching sequence and multidirectional inputs in foundation courses, (ii) correct information, its verifiability and revision, (iii) continuous teacher training with a research base, (iv) efforts to develop manual, cognitive and combinatorial skills, (v) promotion of climate to learn to make mistakes and to correct these, (vi) cultivation of ability to learn to speak, read, write and listen, (vii) promoting contest, dissent expression and nurture of curiosity, and (viii) promoting ability to compare, verify and correct.

I propose a five-year integrated M Sc which would utilize the entire span to deliver life science graduates who can think, perceive, conceive, and copulate information and ideas into knowledge on a sustainable and constructive basis. The proposal eliminates the existing lacunae. Another such proposal suggested earlier³ lacked the conceptual framework, a systematic analysis of the reality, or tenable solutions. The 10+2 syllabi are far better than present the FY B Sc. In my proposal, students can take a B Sc after +3 and leave. A 5-year graduate will have comprehensive subject knowledge, a research base, creative inputs and innovative spirit with a hands-on experience in a research laboratory or field. They will communicate well in modern languages in life sciences, develop self-respect, confidence and fearlessness and maintain high level of curiosity. The system will also promote remedial education to students from rural and socially-deprived backgrounds. Only fully-trained graduates should be licensed to practice life sciences. With a 'micro to macro' synthetic attitude inculcated, it does not matter which specific subject and specialization the student pursues.

The five-year integrated M Sc programme in life sciences

After 10+2, all science subjects should teach similar +3 syllabi with emphasis on the development of communication skills, manual skills, interactive teaching, strong bias for field- and laboratory-training to teach the logic of science and concepts. The present analytical teaching cascade needs to be inverted as a natural mimetic to build a synthetic mind-set with readiness to contest through dissent, combativity for the satisfaction of the curiosity. The consequences of the synthetic approach would be dramatically different on the mind-set and temper. The exposure to management, accounting practices and patent laws will induce students to go into an operational mode for immediate employment in industry. They will become far better teachers and work-

force in science and technology, something that M Sc Biotechnology programme has achieved only marginally.

Summing up

I have evolved a streamlined structure (Table 1) for Life Science education with an exit point, but not entry, after the third year when the student is well trained in basic biology and skills required to promote their access to other professional outlets. The format differs significantly from the classical 3+2 pattern. Similar formats can be developed for other sciences by mini-packaging molecular biology and genetics, cell-developmental biology and immunology, biochemistry and bioenergetics, classical animal, microbial and plant studies, and environmental biology, but not by eliminating these⁴ so that students from other science streams can cross over to life sciences after +3. Students and teachers for such a course should have passed appropriate aptitude tests. Naturally, the present makers of the educational policy need dramatic reorientation, and perpetuation of the practice of 'mandarinage' has to be avoided. Here I refer to the proposal⁴ that ignores the reality of science teaching in India⁵. The process of education should not be under the control of those who are responsible for destroying our educational system as science education requires a level playing field. Otherwise, this model too will end up as the symbol of a failed trial which, at this point, is tantamount to accepting a pawn-status on the scene of rapid globalization. It will also fail if implemented primarily with part-time teachers, howsoever expert and good research scientists they may be, because a student needs continuity in the teacher-contact and a sense of belonging. The implementation will require an aggressive policy to recruit good teachers from within and outside India, to provide a congenial habitat, well-thought procedures for screening students and teachers, equal opportunity, a thoughtful marriage between private and public resources, updatable infrastructure, and methods to promote better performance in students from deprived and rural populace to match the constitutional guarantees without downgrading the educational standards. A good set-up for higher education cannot do away with the research component and must avoid inbreeding. If state governments do not have the will, then the higher education should be entrusted solely in the hands of the central government⁵. Finally, the confidence in the 80+ percentile group at 10+2 needs reassessment because most such students are also products of the so-called parallel education system which the poor students from the lower percentile groups cannot access. This is why a small but measurable proportion of late bloomers appears.

Table 1. Structure of a 5-year integrated M Sc course in life sciences

Year 1. Nuts, bolts and instability	
Semester I	
English for Scientists	Computing, MS Word, Excel, Access, Power point
Measurement theory	Principles of Instability – atoms and molecules
Chemistry–synthesis and catalysis	
<i>Catch-up courses</i>	
Semester II	
Basic electronics	Philosophy of Science – Logic
Statistics and applied mathematics	Biochemistry
<i>Catch-up courses</i>	
Year 2. The cascade of complexity: transmission and the drive	
Semester III	
Molecular Biology	Materials and polymers
Cell Structure and Physiology	Bioenergetics
<i>Catch-up courses</i>	
Semester IV	
Microbial structure, function and taxonomy	Principles of genetics
Developmental biology	Immunology
Carpentry/machine shop/drafting/photography	
<i>Catch-up courses/Year-end summer project</i>	
Year 3. The body	
Semester V	
Structure and function relationships in plants	Structure and function relationships in animals
Animal and plant taxonomy and informatics	Science instrumentation
Biochemical techniques	
<i>Catch-up courses</i>	
Semester VI	
Evolution	Data bases and information retrieval
Ecology	Biophysical techniques
Microtechnique, morphometry and image processing	
<i>Catch-up courses/Year-end summer project</i>	
Year 4. The road and destination	
Semester VII	
Any one among specialized streams, theory and lab rotation	Chronobiology
Optional courses (any two)	Research project and seminars
<i>Catch-up courses/Year-end summer project</i>	
Semester VIII	
Specialized stream theory and lab rotation	Genetic engineering and gene transfer
Optional courses (any two)	Research project and seminars
<i>Catch-up courses/Year-end summer project</i>	
Year 5. Occupational skills	
Semester IX	
Specialized stream theory and lab rotation	Optional courses (any two)
Management	Research project and seminars
<i>Catch-up courses</i>	
Semester X	
Specialized stream (lab rotation)	Optional courses (any two)
Structure of human society, interactions, eugenics	Research project and seminars
<i>Catch-up courses/Year-end summer project</i>

Copyright and patent law
Computer graphics and modelling science
Foreign language proficiency: Japanese or German or French or Spanish or Russian or Arabic

Teaching methodologies. OHP, 35 mm slides, video, CD-ROMs, interactive computer-based teaching (CBT), laboratory and field work, electrical-electronics-mechanical workshop, seminars, tutorials, visits, summer and autumn training programmes, remedial courses.

Examinations. Objective, short and long answer, seminar, open-book, CBT

Funding. Central and state government, private

Infrastructure. Water, electricity, space, equipment and waste disposal

Faculty and students. Aptitude-tested.

Post-script

Unfortunately, our funding agencies lack the correct attitude for critically assessing mission-oriented projects, guts to make mid-course corrections and 'candour' to terminate open-ended and failed projects, be these in universities or national institutes. Most funding reaches a handful few without emphasizing either cost-benefit ratio or the productivity, and that it is almost never terminated despite failures. The applicants often present unattainable objectives using a rhetoric heard sympa-

thetically by the so-called peers who play the musical chairs in a dual role as peers and applicants, and subvert the entire process by breeding rampant nepotism. We really do not have a critical mass of peers for a meaningful peer-review in most hi-tech areas, or low-tech but multifaceted disciplines. Most members of the so-called expert panels do not even read most project proposals. Who, in India will assess proposals, say, from IISc? Who will stop the February gold-rush to Delhi? How can one eliminate the parochialism in research committees? In the West, peer review committees change

through rotation at intervals. We should recruit expert-help from outside, an idea vehemently opposed by the 'mandarins' of Indian science. At present, there is no independent audit of individual or mission-oriented research projects. Like in finance and accounts, the 'spender' cannot be the 'auditor'.

UGC and all Government agencies and NGOs involved in science and technology development in India should support this 'experiment' because it is revolutionary and original. It is a direct attempt to replant the cured soil of higher education in science with an epigenetically modified and better-yielding variety. Only after success in such efforts would we deserve the status of the third largest work-force in science and technology. Indeed, it is worth rerouting this work-force and even decreasing it because the quality, rather than quantity, is relevant to the process of nation building at this point. Even if the part dealing with the +3 level is implemented, the scenario for life sciences will change dramatically in India. A 5-year M Sc programme is not

another band-wagon to attract 'good' students. It must transcend geo-political considerations. Indian teachers are parochial and hate mobility. Then, let students move, as they do, to the training site. The psychological 'fix' by a 5-year M Sc⁶ will automatically curtail the use of students as the 'manual labour' for the peers practising science by 'proxy'.

REVIEW ARTICLE

Progress towards malaria vaccine

V. S. Chauhan

International Centre for Genetic Engineering and Biotechnology, Aruna Asaf Ali Marg, New Delhi 110 067, India

Resurgence of malaria has reached alarming proportions. The situation has become worse because of the widespread resistance to anti-malarials. Thus malaria vaccine research has become an area of intense activity even though host-parasite interactions are not well understood. Several antigens from different stages of the life cycle of malaria parasite have been identified. It is now clear that both antibodies and cellular immune responses are involved in malaria immunity. At the

same time it is becoming clear that plasmodium has developed exquisite mechanism to evade the immune responses mounted by the host. All kinds of vaccine constructs, based on recombinant antigens, synthetic peptides, and direct use of DNA are being attempted and several of these are undergoing human trials. Results of these trials and other research works clearly indicate that malaria vaccine development is hugely complex and success may not come easily.

MALARIA continues to be a major cause of morbidity and mortality in the tropical and subtropical areas of the world where approximately 350 million malaria cases occur each year. More than two million children die of the disease annually. The overwhelming success of chloroquine as a drug and DDT as an insecticidal, introduced in 1960s resulted in an impression that malaria could be controlled to a large extent if not eradicated. Unfortunately, resistance of the human malaria parasite *Plasmodium falciparum* to anti-malarial drugs and to its mosquito vector to insecticides has led to an alarming situation and drugs-resistant strains of *P. falciparum* have spread throughout the tropics. Given the fact that

no new anti-malarial drugs or new insecticides superior to DDT are likely to be available in the near future, the disease situation is becoming hopeless.

Vaccine should be a useful addition to chemotherapy and the vector control program in malaria control. However, until recently there was no way to obtain sufficiently large amounts of antigenic material from the parasite. With the availability of *P. falciparum* in culture form, it has become possible to study the molecular basis of the parasite function. Identification and production of antigens involved in protective immunity by applying tools of modern biology has changed the direction of malaria research, particularly the vaccine development.

There are four species of human malaria: *P. falciparum*, responsible for practically all malaria deaths, *P. vivax*, also widespread and the cause of considerable morbidity, and the less prevalent species *P. ovale* and *P. malariae*. The parasite undergoes a complex life cycle. There are three major stages in the life cycle and each of the developmental stages is morphologically and antigenically distinct and there appear to be several antigenic molecules at each stage that could be potential vaccine targets.

Malaria vaccines against the three distinct developmental stages of the parasite are being developed^{1,2}. Vaccines against the pre-erythrocytic stages of malaria aim to eliminate infection by blocking sporozoites from entering hepatocytes or by destroying the infected hepatocytes. The second type of vaccine targeted against the blood stages of the parasite which would be expected to prevent the disease or significantly reduce the parasite load, and therefore the intensity of infection. The third type is aimed at the sexual stages of parasite and aims to limit transmission of the disease. An altogether different kind of vaccine, namely anti-disease vaccine, has also been proposed³. Such a vaccine would aim to neutralize factors responsible for the pathology associated with malaria infection. Keeping in view our own research in the malaria research group at ICGEB, the main focus of this review will be on sporozoite and blood stage based vaccines.

Despite tremendous progress in malaria research during the past twenty years which has led to a vast amount of information, the exact nature of malaria immunity and effector mechanisms involved remain ill understood. Malaria immunity is slow to acquire and is usually short-lived. Thus, children up to 5 years of age are most susceptible to severe clinical disease; adults show little parasitaemia and rare clinical disease. The highly polymorphic nature of malaria antigens within each parasite species and antigen structure are proposed to be the main reasons for the slow and transient nature of the acquired immunity. Further, the immunity is both species- and stage-specific. A person with immunity to *P. falciparum* may still be susceptible to *P. vivax* infection and vice versa. Similarly, immunity to the sporozoite stages may still leave an individual susceptible to the blood stage infection. It is often thought that a successful malaria vaccine will have components from several antigens belonging to the different stages of the parasite. However, non-availability of a suitable animal model for human malaria will remain a major hurdle in the development of malaria vaccines.

Is there a rationale for a malaria vaccine?

Given the complexity of the parasite's life cycle, complicated and ill-understood host-parasite interactions

and several mechanisms that are operative in favour of the parasite to evade immune responses, it does appear that development of an antiparasite vaccine will be a very difficult task, if not an impossible one. On the other hand, there are several reasons to believe that malaria vaccine will be developed in future. Some of these are:

1. Individuals living in malaria endemic areas do develop specific immunity that decreases the parasite's ability to survive in the human host and also decreases the clinical consequences of infection. However, in contrast to rapid and long-lasting immunity induced during viral infections, malaria immunity takes a long time to develop and is usually short lived in absence of continued exposure to infection. Clearly a successful malaria vaccine will have to be more effective at inducing immunity than the natural infection.

2. Transfer of immunoglobulin from individuals with acquired malaria immunity, to naive humans almost completely protected them from infection⁴.

3. Immunization with irradiated sporozoites induces a solid immune protection in animals^{5,6} and in humans⁷. However, only intravenous deposition of irradiated sporozoites, not a convenient route for general vaccination, provides optimum protection.

4. Significant levels of protection were observed in early trials when purified malarial antigens were used as immunogens^{8,9}. More recently, several trials with recombinant antigens have shown high levels of protection against challenge with blood stage parasites^{10,11}. This is encouraging for vaccine developments since only a few antigens, out of the numerous suggested have actually been tested in primates. It is very much possible that valuable vaccine antigens will be discovered and used as vaccine candidates.

Nature of malaria vaccines

Most successful vaccines have been based on attenuated or killed pathogens. Since human blood is needed for *P. falciparum* culture and *P. vivax* has not yielded to culture at all, the focus in malaria vaccine development is largely limited to well-defined molecules which can induce protective immune responses and now be easily produced by recombinant DNA techniques in various systems. While a recombinant hepatitis B vaccine is already in use in humans, several other recombinant vaccines are in the developmental stage.

The fact that immune response against short peptide can produce neutralizing antibodies against viral and other proteins, has opened way to the development of synthetic peptides as immunogens for vaccination¹². But short peptides are usually poor immunogens, and the carrier proteins that are traditionally used to enhance their immunogenicity have inherent problems associated

with their use¹³. Use of T cell determinants in place of carrier proteins is being investigated¹⁴⁻¹⁶.

Viral vectors including vaccinia and salmonella have been considered as vehicles for carrying the gene of a target antigen. More recently, direct DNA immunization has also been attempted in malaria vaccine development¹⁷. The main attraction of developing viral vectors or direct DNA immunization protocols is that it obviates the use of adjuvants which are necessarily needed in case of recombinant proteins and synthetic peptides.

Liver stage antigens

The early observation that immunization with irradiated sporozoites could protect rodents or humans against challenge with viable sporozoites provided the basis for much of the work on the sporozoite stage vaccine⁵⁻⁷. It is now clear that both humoral and cell-mediated immune functions contribute to the acquired immunity in man. In rodent model system also, antibodies to the circumsporozoite protein, CD⁴⁺ cells and CD⁸⁺ T cells have all been implicated in protection. Of the liver stage proteins, the circumsporozoite (CS) protein has primarily been the focus of most studies in both rodents and humans¹⁸.

The CS protein covers the whole surface membrane in mature salivary glands, of all malaria species sporozoites and is believed to be involved in the process of sporozoite's penetration into hepatocytes. All CS proteins have an immunodominant epitope in the middle region formed by tandem repeats of amino acids, which vary in sequence among different species of malaria parasites. It was observed that antibodies to the epitopes formed by the repeats mediate protection against sporozoite-induced malaria. This led to the first generation of subunit malaria vaccines to be tried in humans. Two candidate vaccines based on (Asn-Ala-Asn-Pro) repeats were developed. One of these was a recombinant polypeptide (R32tet32), containing thirty two *P. falciparum* CS repeat units, fused to a sequence of 32 amino acid residues from the plasmid vector. The other vaccine consisted of synthetic dodecapeptide, (Asn-Ala-Asn-Pro)₃, which represents the epitope recognized by antibodies in the sera of humans living in endemic areas, conjugated to tetanus toxoid. However, both the constructs were poorly immunogenic in humans, when administered in alum^{11,19}. Limited protection which correlated with the levels of anti-repeat antibodies was observed but by and large these trials were considered unsuccessful. Similarly in another human trial, poor immunogenicity was again observed when a recombinant CS protein of *P. vivax* was administered in alum²⁰. It was soon realized that a successful anti-sporozoite vaccine will have to induce high antibody levels to the repeat sequence with the appropriate specificity. It is

now clear some parasite antigens like the CS protein are poorly immunogenic because the helper T-cell epitopes lie mostly in the polymorphic region of the protein. A vaccine dependent on a foreign carrier protein to provide T-cell help may provide high primary antibody response, but will not respond to subsequent parasite challenge, and therefore will not be effective unless administered repeatedly.

The target for cellular immunity can be any antigen, surface or internal of the parasite, containing one or more T-cell epitopes. Sensitized T-cells may secrete γ -interferon or other lymphokines including tumour necrosis factor or oxygen species which are known to kill parasites²¹. Further, cytotoxic T-cells (CD⁸⁺), in addition to activating the non-specific effector functions, may also recognize specific epitopes on parasite-infected hepatocytes and kill them. While T cell responses to CS protein have been studied in some detail, recently, two other liver stage antigens namely, the sporozoite surface antigen 2 (SSP-2) and the liver stage antigen 1 (LSA-1) have been characterized and their immune responses in humans and in animals are being evaluated, in order to develop these antigens as possible vaccine candidates^{22,23}.

Asexual blood stage antigens

Antibody response to the asexual blood stages of malaria parasites is extremely diverse. A very large number of polypeptides are recognized by antibodies in the serum of malaria-infected individuals. Selection of suitable candidate proteins from a very large number of antigens is itself a major difficulty in the development of a blood stage malaria vaccine (Table 1). Since the titre of antibodies to the blood stage antigens does not correlate with protection, it is quite possible that most antigens do not produce protective responses. The immediate goal, therefore, is to identify the antigens capable of inducing protective immune responses.

Non-availability of a suitable animal model is another major block in the way of malaria vaccine development. Although a vaccine target antigen for *P. falciparum* can be tested in Aotus or Saimiri monkeys, the infection in monkeys takes somewhat different course than the human disease. Moreover these monkeys are not easily available. For these reasons, indirect criteria such as location and the possible function of the antigens are often used in choosing a possible protective antigen. Some of the major vaccine target antigens from the blood stages of the malaria parasites are briefly described below.

Most protection studies with recombinant polypeptides fragments or chemically synthesized hybrid peptides have focused on a relatively small number of antigens. Major surface protein 1 (MSP-1) was one of

the first antigens identified as a potential vaccine candidate. It contains variable and highly conserved regions and is synthesized as a large protein, anchored to the merozoite surface and undergoes processing in two steps. Recombinant fragments representing the MSP-1 conserved regions were found to induce partial protection in Saimiri monkeys²⁴. That immunogenicity of peptide fragment can be highly enhanced by covalently attaching it to suitable T helper cell epitopes was shown in case of a conserved MSP-1 fragment, and higher levels of protection were observed in monkeys with such a construct²⁵. A significant result of these studies was the speculation that the protection was at least partially T-cell mediated. We have also characterized B and T-cell epitopes in the conserved regions of MSP-1 and have used these epitopes in the design of multiple epitope peptides²⁶. The C-terminal 19 kDa fragment, highly rich in cysteine residues, which are found conserved in several species of *Plasmodium*, appears to be crucially involved in merozoite invasion of erythrocytes and is carried into cells by invading merozoites²⁷. Phase one and phase two clinical trials using this fragment are being planned in the USA.

The second merozoite surface protein (MSP-2) is a 45 kDa protein located on the surface of the merozoite. The molecule contains a variable central repeat region, but the N and C terminal regions are highly conserved. Synthetic peptides from these conserved regions of Pf MSP-2, conjugated to a carrier protein, provided significant protection against *P. chabaudi* challenge in mice²⁸. Phase I trials with a combination of MSA-2 and the CSP protein have been conducted in Australia. Apical membrane antigen (AMA-1) is another protein that is highly conserved in all species of plasmodium analysed so far²⁹. Monoclonal antibodies against this antigen inhibit merozoite invasion of red cells and currently this antigen is undergoing human trials as a vaccine candidate. Genes for blood stage proteins like the acid base rich antigen (ABRA), the ring-infected erythrocyte surface antigen (RESA), the serine rich antigen (SERA), erythrocyte binding antigen (EBA-175) and several other malaria antigens (Table 1) have been cloned and sequenced³⁰. These antigens are at different stages of development for their potential as vaccine target antigens^{30,31}. Immunization studies with these antigens, produced by recombinant methods have resulted in a wealth of information which ironically reveal that malaria immunity might be more complex than thought earlier. As a result of this it is now believed that an approach of combining several conserved antigens in a cocktail vaccine might be more successful in addition to providing a means to reduce the risk of the selection of vaccine resistant forms of the parasite. An attenuated live vaccinia virus-based vaccine consisting of seven candidate antigens from the different life stages of the parasite, known as NYVAC-7, is being tested in humans for safety and immunogenicity in the USA.

Synthetic peptides as malaria vaccines

An alternative to the use of full length recombinant or native antigens is to identify the peptide epitopes on immunogens which induce a protective response and to use synthetic versions of the peptides in the production of vaccines. This approach seems particularly suited for parasitic diseases where it is increasingly being realized that some crucial epitopes of vaccine target antigens remain cryptic during immunization with the native antigens.

A synthetic peptide-based polymer, termed as SPf 66, developed by M. E. Patarroyo in Colombia, has undergone extensive human trials in several locations in Latin America and more recently in Africa and South East Asia³²⁻³⁵. The basic unit of SPf 66 as a hybrid peptide represents epitopes from CS protein, MSP-1 and two other sequences from yet-to-be-characterized 35 kDa and 55 kDa proteins from the blood stages of the parasite^{36,37}. Following the protection experiments in monkeys, the first human trials with SPf 66 were conducted in South America where high levels of protection were reported³³. These and subsequent results from a field study conducted in Tanzania confirmed that the vaccine was safe, induced anti-SPf66 antibodies and was able to provide up to 30% protection in the immunized children³⁴. However, more recent and carefully-designed studies conducted in The Gambia and in Thailand have shown³⁵ that SPf 66 could not provide any protection at all. It is now more or less accepted that this vaccine is not protective in areas of high malaria endemicity and that further efficacy trials are not warranted³⁵. This has been a major setback to malaria vaccine development and the question as to why SPf66 has failed after initial promise of partial protection does become a relevant one, in particular with respect to field trials involving future vaccine candidates.

The development of SPf66 has been full of controversies, ranging from scientific criticism to the issue of attitudes towards research carried out in a developing country. M. E. Patarroyo published in 1988 his findings that SPf66 was partially protective against *P. falciparum* infection in both Aotus monkeys and humans^{36,37} and since then insisted that SPf66 is a viable malaria vaccine. His enthusiasm has never been shared with vigour by other scientists³⁸ which was partly due to the fact that two independent trials with SPf66 in monkeys failed completely^{39,40}. The protection observed in large field trials in Latin America was also subjected to debates on the basis of inadequate epidemiological design of these trials and claims that SPf66 could also protect against *P. vivax* infection; the latter certainly appeared implausible. These arguments were certainly rational and intellectually justifiable. However, it should be pointed out that the same arguments could equally well apply to several clinical and field trials, including some peptide

based malaria vaccines, performed by scientific institutions in the developing world who were critical of Pataroyo's claims. Looking back, however, it does seem that the simple approach of attempting to produce a minimalist mimic of the malaria parasite was ambitious, just as it must be said once again, were the human trials conducted in the USA with the synthetic constructs based on repeat structures of the CS protein. Doubts about the design of the earlier field trials with SPf66 were, however, removed in the later trials done in collaboration with WHO/TDR in Tanzania. But the most puzzling observation in all these human trial studies^{33,34} was the fact that while SPf66 produced antibodies upon immunization, it had no correlation with the observed protection^{33,34} was being achieved. Perhaps some unknown protective mechanisms were involved. In the end, however, the inability of other workers to reproduce some of the key results described for SPf66, along with the results of the recent human trials in The Gambia and Thailand does seem to suggest that there is little chance that it will be used as a vaccine against malaria. Be that as it may, the development of SPf66 has certainly established that a chemically synthesized peptide construct can be a safe immunogen in humans, and has opened way for the development of other peptide-based vaccines.

Malaria research at ICGEB

Some of the major malaria antigens have within their structures regions that are highly conserved, not only within the different strains of the parasite but also among different species of malaria parasite. It has been argued that it is most meaningful to base vaccine constructs on the regions that have remained conserved under immunological pressure; such sequences are more likely to represent functional domains of the parasite surface proteins. My research group at ICGEB has followed this approach to develop synthetic peptide immunogens as malaria vaccine candidates, to be initially tested in animals.

A special feature of most malaria proteins is the presence of immunodominant repeat peptide structures⁴¹. There is also extensive antigenic cross-reactivity reported in malaria and these factors appear to be involved in immune evasion mechanisms developed by the parasite⁴². To probe if the repeat structures contribute to the observed cross-reactivity among the known antigen of *P. falciparum*, we synthesized peptides based on repeat structures from different antigens of *P. falciparum* and were able to show in a specific manner that the humoral immune responses to these peptides are highly cross-reactive⁴³. Circular dichroism studies on these peptides revealed that these peptides tend to adopt helical structure in solution. However, it is not clear if the

preference of repeat peptide structures for a given secondary structure alone is responsible for the observed immunological cross-reactivity³⁶. Interestingly, we found that the peptides based on *P. vivax* repeat structures did not show any significant cross-reactivity with the *P. falciparum*-based peptides (unpublished work, Chauhan *et al.*). It is now firmly believed that highly immunodominant repeat structures are utilized by the parasite to evade immune responses mounted by the host. It is also being suggested that epitopes crucial for the parasite survival may remain mostly hidden, and although functionally relevant, they may not be as accessible to the immune system of the host as the structurally dominant repeat structures. Delineation of such conserved, perhaps cryptic, epitopes may be necessary to the design of a peptide-based malaria vaccine.

The epitopes recognized on a protein may be linear or spatial: B-cell epitopes, involved in the recognition of antigens by antibody, may be either linear or discontinuous, but the T-cell epitopes, involved in cell-mediated immunity and T helper activities, are invariably linear. Peptides themselves are poor immunogens and usually need to be conjugated to a suitable protein to obtain an immune response. We were able to show that immunogenicity of a B epitope from Pf MSP-1 could be enhanced by linking it covalently with a T-cell epitope sequence from the CS protein or tetanus toxoid¹⁶. There is increasing evidence that highly enhanced and specific immune responses can be obtained by combining B-cell epitopes with Th epitopes although

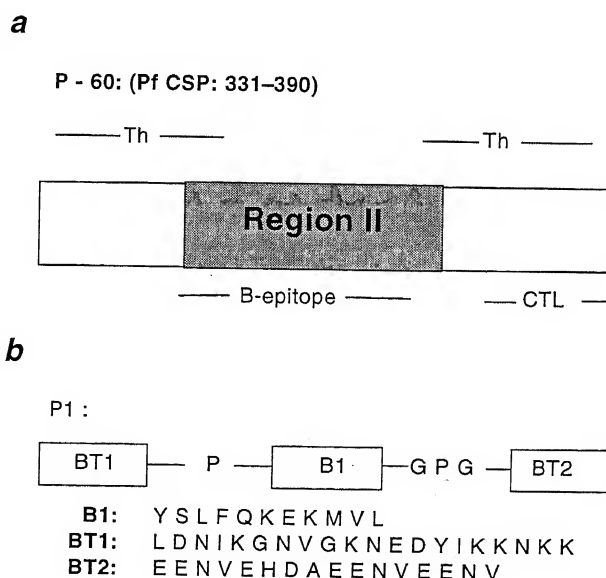

Figure 1 a, b. Schematic representation of P60 and P1 indicating the location of different epitopes. **a**, At the N-terminus of P60 is a Th epitope (amino acid residue no. 331-349 of the CSP) overlapping a B epitope in region II (residues 346-363 of the CSP), followed by another Th epitope (362-381) and an overlapping CTL epitope (368-390). **b**, BT1 and B1 are peptide sequences from MSP-1 whereas BT2 is a peptide sequence from RESA in a hybrid peptide P1.

Table 1. Asexual stages vaccine target antigens

Antigens	Approx. size	Location
Sporozoite/liver stages		
Circumsporozoite surface protein (CSP)	60 kDa	Sporozoite surface
Sporozoite surface protein-2 (SSP-2)	63 kDa	Sporozoite surface, Micronemes
Liver stage antigen-1 (LSA-1)	200 kDa	Parasitophorous vacuole
Sporozoite threonine asparagine rich protein (STARP)	70 kDa	Sporozoite surface
Blood stages		
Merozoite surface protein-1 (MSA-1)	195 kDa	Merozoite surface
Merozoite surface antigen-2 (MSA-2)	45 kDa	Merozoite surface
Apical membrane antigen-1 (AMA-1)	83 kDa	Rhoptry organelle
Rhoptry antigen protein-1 (RAP-1)	80 kDa	Rhoptry organelle
Rhoptry antigen protein-2 (RAP-2)	42 kDa	Rhoptry organelle
Ring erythrocyte surface antigen (RESA)	155 kDa	Dense granules
Acid base rich antigen (ABRA)	75 kDa	Parasitophorous vacuole
Histidine rich protein-2 (HRP-2)	65 kDa	Secreted into plasma
Serine repeat antigen (SERA)	110 kDa	Released at rupture
Pf Erythrocyte membrane protein-1 (PfEMP-1)	250–400 kDa	Parasitized erythrocyte surface
Erythrocyte binding antigen-175 (EBA-175)	175 kDa	Micronemes/Apical end
Thrombospondin related anonymous protein (TRAP)/(SSP-2) ?	63 kDa (?)	(?)

Table 2. Multiple epitope peptides developed at ICGB

Peptide	Sequence	Antigen
P1	LDNIGNVVGKNEDYIKKNKKPYSLFQKEKMVLGP GEENV EHD A EENV EENV	MSP-1/RESA
P18	EWSPCSVTCTGNGIQVRIK	CSP
P32	IEQYLKKIKNSISTEWSPCSVTCGNGIQVRIK	CSP
P60	IEQYLKKIKNSISTEWSPCSVTCGNGIQVRIKP GSANKPKDEL DYENDIEKKICKMEKCS	CSP

the manner in which this can be done still needs to be worked out. Design of synthetic peptides containing disease relevant B and T epitope sequence in order to generate specific immune responses is central to the development of peptide vaccines.

Carboxy-terminal to the repeats, CS proteins from all *Plasmodium* species possess a conserved region (region II) centered around a cysteine containing nonapeptide sequence, WSPCSVTCTG, also found in proteins involved in cell-cell interactions, such as thrombospondin, properdin, etc. Results from our laboratory and the works of others have clearly indicated that region II is a sporozoite ligand for the hepatocyte receptor^{44,45}. We were able to show that two peptides, based on the *P. falciparum* region II sequence, P18 and P32 (Table 2) significantly inhibited *P. berghei* sporozoite invasion into HEP-G2 cells⁴⁵. Quite significantly, we also found that antibodies to P32 also inhibited *P. berghei* sporozoite invasion of Hep-G2 cells. Since P32 contains a strong T-cell determinant in addition to the conserved region II motif, we immunized mice with P32 without using a carrier protein. Significant immune re-

sponses were obtained in two different strains of mice. The fact that immunization of mice with P32, without the use of a carrier protein, protected them against a lethal challenge of *P. berghei* sporozoites strongly suggests that P32 contains crucial B and T-cell epitopes and that region II may be useful as a component of a malaria vaccine⁴⁵.

Surprisingly the conserved nonapeptide sequence of the region II is also present in another sporozoite surface antigen called thrombospondin related adhesive protein (TRAP or SSP-2), which also has been recognized to play a crucial role in the sporozoite invasion of hepatocytes⁴⁶. Although first described from the blood stages, the expression of TRAP during the erythrocytic stages of the parasites has been controversial⁴⁶. We have found that antibodies raised against a synthetic peptide containing the conserved nonapeptide motif recognized a protein in the blood lysate of *P. falciparum* culture⁴⁷. Immunoprecipitation experiments with antibodies raised against recombinant TRAP, and its fragments, provided further evidence for the presence of a TRAP-like protein during the blood stages of *P. falciparum*. Further, we

found that anti-peptide antibodies inhibited merozoite invasion of erythrocytes⁴⁷. Mice immunized with synthetic peptides P32 or P60 (Table 2), both of which contain several B and T epitopes (Figure 1a) including the region II sequence, were partially protected against a heterologous challenge with blood stage parasites of *P. yoelii*⁴⁸. Immunization with P60 in rhesus monkeys also produced high anti-peptide antibody response. Protection experiments in Aotus monkeys with P60 have been planned. Fine specificity of the immune responses to these peptides with respect to various B and T-epitopes showed that the response was focused on the region II sequence. From the cytokine analysis data we observed that both Th1 and Th2 cellular responses were induced upon immunization with the peptides⁴⁸. Our results clearly show that through the use of appropriate peptide it may indeed be possible to focus the immune response to the regions which otherwise remain largely cryptic during the course of natural infection or upon immunization with recombinant or native proteins.

It is generally believed that a future malarial vaccine will need to contain a combination of different antigens. Synthetic peptide constructs containing B and T-epitopes from different antigens have been developed, but a major concern with epitope-based constructs is the genetic restriction of the immune response in an outbred human population. Characterization of B and T-cell determinants in a viral or parasite antigen may be relatively simple now, given the advances in peptide synthesis, theoretical prediction of antigenic sites and a battery of simple assays. We have analysed immune responses to a series of synthetic peptides representing predicted B and T-cell determinants from conserved regions of MSP-1, TRAP, RESA and AMA-1. Analysis of the development of immune response to specific immunodominant peptide fragments from different major malaria antigens revealed a direct correlation of malaria-specific antibodies with transmission of the disease²⁶. One of the peptides, representing repeat structure peptide of RESA has turned out to be a good marker and may be used as a capture antigen in ELISA to determine the status of malaria control programme⁴⁹.

Based on B and T-cell epitopes of liver and blood stage antigens, CS protein, and MSP-1 and RESA, respectively, two multiple epitope peptides, P1 and P2 (ref. 50) were designed and synthesized (Table 2). These linear peptides were highly immunogenic in mice without the use of a carrier protein and both peptides were able to induce cellular proliferative responses⁵¹. We also studied the effect of different adjuvants on the immunogenicity of these peptides and found that in alum also these peptides are excellent antigens. Interestingly immunization with P1 (Figure 1b) provided protection to BALB/c mice against a heterologous, *P. yoelii* challenge infection. However, P2, which also contains similar B and T epitopes, but in different orientation, failed

to provide any protection. We found that in case of P2 immunization the humoral response was focused on T-epitope sequence instead of the B-cell determinant⁴⁴. Our results suggest, as indeed from several other groups working on peptide vaccines, that while linear multiple epitope peptides may offer attractive alternatives as subunit vaccines, it is clear that ground rules for the design of such immunogenic peptides are yet to be defined⁵¹⁻⁵³.

It is obviously important to analyse whether the epitopic sequences from malaria antigens are immunogenic in the context of infected individuals living in malaria-endemic areas. Even though most of our work involves the use of highly-conserved regions of the vaccine target antigens, it will be of relevance to characterize these antigens from Indian isolates of *P. falciparum*; surprisingly none of these antigens have been characterized as yet. As a step in this direction we have isolated, cloned and sequenced the gene of the MSP-2 from three geographical isolates from different malaria-endemic areas in India. The MSP-2 gene of Indian isolates is remarkably similar to the FC-27 strain from Papua, New Guinea⁵⁴. We are now in the process of characterizing genes of MSP-1, CS protein, TRAP and AMA-1 of *P. falciparum* from Indian isolates.

P. vivax/P. cynomolgi malaria

Of all the malaria cases in India up to 60 to 70% are due to *Plasmodium vivax* infection and although *P. vivax* infection does not directly kill the host, it causes a great deal of discomfort and morbidity. Relatively less is known about the immune responses of the host to *P. vivax* infection. Also, the antigens of *P. vivax* are not as well characterized as *P. falciparum*, mainly because unlike *P. falciparum*, *P. vivax* has resisted all attempts of culturing the parasite; infected humans remain the only source of the parasite material. *Plasmodium cynomolgi* is a simian malaria which is closely related to *P. vivax* in taxonomy and morphology, and is regarded as a good model to study the *P. vivax* infection⁵⁵. We have characterized genes of three major vaccine target antigens from a *P. cynomolgi* isolate, obtained from the Central Drug Research Institute, Lucknow, in order to test their potential as vaccine candidates in the readily available rhesus monkey model. We found that the AMA-1 of *P. cynomolgi* is closely related to the *P. vivax* counterpart, and most structural features like number and position of cysteine residues and proline residues are conserved in the two homologues⁵⁶. The full length AMA-1 and a truncated version of it have been expressed in *E. coli* and baculovirus system, in our laboratory. This will allow us to investigate the immune responses to Pc AMA-1 in the monkey model, and thus to analyse its role in protective immunity during the blood stages of the parasite.

REVIEW ARTICLE

Another important vaccine target antigen, TRAP, is also a major focus in our laboratory for analysing its role in malaria immunity. We have observed that certain highly conserved B-cell epitopes of the Pf TRAP remain cryptic during the course of natural infection. The ability to make important functional epitopes cryptic appears to be a general strategy of parasites to evade host's immune responses as has been shown in case of surface protein of *Trypanosoma cruzi*⁵⁷. We have cloned and expressed in bacteria the full length TRAP gene of *P. falciparum* from an Indian isolate, and its fragments, representing the N and C-terminal domains of the protein. Since TRAP is considered one of the most conserved malaria antigens, we have also characterized the TRAP gene from *P. cynomologi*⁵⁸. The potential of this antigen and their fragments in protection will be tested in a relevant animal model. Since TRAP is highly conserved across the *Plasmodium* species, the results of *P. cynomologi* experiments will be of direct relevance in evaluating its role in *P. vivax* and *P. falciparum* vaccine development.

As mentioned earlier, it appears that the ability to block the development of immune responses to the functional epitopes is one of the main strategies to evade immune responses of the host. This is why a synthetic peptide-based vaccine development approach may be most relevant in a parasite disease like malaria. Through the use of peptides it may be possible to focus immune responses to the otherwise cryptic epitopes; development of synthetic peptides as immunogens is, therefore, an immediate need for parasite vaccines. However, genetic restriction of immune response, specificity of epitopic sequences, use of appropriate adjuvants, etc. are some of the problems that will have to be sorted out before peptides may be useful for vaccination. With the availability of recombinant antigens and their fragments in our laboratory, it should now be possible for us to compare the immune responses obtained upon immunization with whole antigens with those obtained from the use of synthetic, multiple epitope peptides. For the development of vaccines against parasitic diseases, this appears to be one of the most important questions.

What's the essence of royalty – one keto group?

Raghavendra Gadagkar

Centre for Ecological Sciences, Indian Institute of Science, Bangalore 560 012, India and Jawaharlal Nehru Centre for Advanced Scientific Research, Jakkur, Bangalore 560 064, India

A honey bee colony consists of a single queen, tens of thousands of nearly sterile female workers and usually a few hundred drones. The presence of the queen inhibits rearing of new queens, stimulates foraging and interaction of workers with the queen and, (along with the queen's brood), inhibits the development of worker ovaries. Most or all of these effects of the queen on the workers are mediated through primer pheromones secreted by the queen. An important component of the queen's pheromone blend is 9-keto-(E) 2-decenoic acid (9-ODA). Workers also produce related substances which appear to function as nutrients and food preservatives. A dominant component of the worker blend is a diacid which is made from a precursor molecule hydroxylated at the ω

carbon atom rather than at the $\omega-1$ carbon atom. The $\omega-1$ precursor is used by the queen which leads to the formation of a keto acid. One might say that the fundamental difference between a queen and worker, the essence of royalty is therefore, one keto group! The recently-elucidated caste-specific biosynthetic pathway for the production of these pheromones permits two other speculations. One is that workers can be thought of as being closer to the ancestral solitary condition and that queens can be thought of as a derived invention of sociality. The other is that, compared to non-social species, social insects are especially predisposed to evolve novel structures and characters as exemplified by the queen for example, through the process of evolution of gene duplication.

Honey bees

WILLIAM Morton Wheeler¹ says of the honey bee: 'Its sustained flight, its powerful sting, its intimacy with flowers and avoidance of all unwholesome things, the

attachment of the workers to the queen – regarded throughout antiquity as a king – its singular swarming habits and its astonishing industry in collecting and storing honey and skill in making wax, two unique substances of great value to man, but of mysterious origin,

made it a divine being, a prime favourite of the Gods, that had somehow survived from the golden age or had voluntarily escaped from the garden of Eden with poor, fallen man for the purpose of sweetening his bitter lot.' Today one might add, 'and also for the purpose of providing him with a model system to study everything he wishes to know about animals'. Honey bees have served as an excellent model system in animal behaviour, sociobiology, physiology, genetics and biochemistry. Above all the discovery by Karl von Frisch², of colour vision in the honey bee and of its ability to use ultraviolet as another colour and see patterns in flowers that we cannot, and his elucidation of the dance language of the honey bee have created in us a new respect for animals. In the words of J. L. Gould, 'The lesson is a melancholy one. We are blind to our own blindness and must not try to read our disabilities into the rest of the animal kingdom.' Now honey bee queens and workers are on the threshold of teaching us the essence of royalty and the lesson is an even more melancholy one – the answer seems to be, one keto group!

The queen pheromone

Honey bees live in populous colonies consisting of tens of thousands of sterile workers, a few hundred drones and a single fertile female, the queen. The queen affects the workers in several ways^{3,4}. The presence or absence of the queen is detected by the workers in a matter of minutes. The presence of the queen normally prevents the workers from rearing new queens. Also, the presence of the queen and her brood inhibits the development of the worker's ovaries; in the event of the death of the queen, however, workers do develop their ovaries and lay small numbers of unfertilized haploid eggs. The queen is always surrounded by an ever-changing retinue of about 10 workers at a time who feed and lick her. Most or all these effects of the queen on the workers are mediated by pheromones secreted largely from a pair of mandibular glands on either side of her head. Pheromones are chemicals, usually but not always volatile, secreted from exocrine glands of animals which serve to elicit behavioural or physiological responses in conspecifics and thus serve as chemical messengers⁵. The best-known pheromones such as bombykol, the sex pheromone of the silk moth that helps the male find his mate with incredible sensitivity, are seen to release specific and instantaneous behavioural responses and hence are termed *releaser* pheromones. The honey bee queen pheromone on the other hand, has more complex and fundamental effects on workers, including inhibition of their ovarian development and is hence termed a *primer* pheromone. The queen bee pheromone (which acts both as a releaser and primer pheromone)⁶ is a blend of several chemicals not all of which may yet be known.

However Mark L. Winston and Keith N. Slessor of Simon Fraser University in British Columbia, Canada, have succeeded in identifying five of the most essential components of the queen pheromone which together elicit most of the important behavioural responses expected from the workers⁷. One queen equivalent of what I will call the Winston-Slessor blend (although they prefer to call it QMP, for queen mandibular pheromone, to emphasize their team work involving a large number of other people), consists of about 200 µg of 9-keto-(E)-2-decenoic acid (9-ODA), about 80 µg of 9-hydroxy-(E)-2-decenoic acid (9-HDA), of which about 56 µg is the (–) optical isomer and about 24 µg of the (+) optical isomer, about 20 µg of methyl *p*-hydroxybenzoate (HOB) and about 2 µg of 4-hydroxy-3-methoxyphenylethanol (HVA) (Figure 1). The latter two aromatic compounds are minor and indeed, somewhat unexpected components. On the other hand the aliphatic 9-ODA and 9-HDA are the major components whose involvement in the honey bee queen pheromone has been known for a long time.

The Winston-Slessor blend

The Winston-Slessor blend elicits a clear-cut retinue response, indeed that is how it all started when Kaminiski, Slessor and Winston⁸ noticed that stray worker bees formed a retinue around a glass vial containing a crude extract of the queen mandibular gland. Much of their subsequent work is based on a bioassay based on the retinue response that workers so readily show to the chemicals *sans* the queen bee. The blend also mimics the queen's ability to inhibit queen rearing by the workers. In the event of the death of the queen, workers resort to emergency queen rearing by enlarging some of the cells containing young (< 3 days old) larvae and feeding the chosen larvae with 'royal jelly' and thus channeling them into a developmental pathway leading to the formation of queens. When workers in queen-less colonies were given one queen equivalent of the blend per day, emergency queen rearing was almost completely inhibited. Although the blend elicited other expected responses such as inhibition of swarming, it did not inhibit worker ovarian development, which is therefore thought to be a function of a different primer pheromone not included in the Winston-Slessor blend (and of the brood). An unexpected effect of the blend was its stimulation of pollen foraging and brood rearing. By spraying crops with the blend and showing that more bees visit the crops and whose yield then increases due to better pollination, Winston and his colleagues have demonstrated a promising commercial application of their basic research – what a sigh of relief in this day when there is so much pressure to make economic sense of all scientific research!

Figure 1. The Winston-Slessor blend of honeybee queen pheromone containing well-defined amounts of five of the most important components of the mandibular gland secretion, which elicits most of the responses expected from workers. See text for expansion of the names of the components.

Queen-worker dichotomy

Having made some economic sense, we deserve the freedom to turn our attention once again to a whole new intellectually challenging question. Perhaps the most fascinating aspect of honey bee colonies is the differentiation of the bees into a sterile worker caste and a fertile queen caste. The question that stems from this observation relates to the possible differences between queens and workers in their pheromone blends and the mechanism of the origin of these differences. These are the questions that Plettner *et al.*⁹ address in a recent path-breaking paper. Workers too produce mandibular gonad secretions that are added to the brood food and may serve as preservatives and nutrients. Instead of the two major components of the queen's secretions namely, 9-ODA and 9-HDA, workers secrete acids hydroxylated at the 10th or ω -carbon atom rather than the 9th or $\omega-1$ carbon atom as in the case of the queen's acids. Instead of the queen's 9-HDA, workers secrete 10-hydroxy-(E)2-decenoic acid (10-HDA) and instead of the queen's 9-ODA, workers secrete the diacid derived from their 10-HDA. In other words, queens and workers differ essentially only in the position of the carbon atom that is hydroxylated. But how does this difference arise? As a result of a series of experiments involving analysis of the fate of deuterated test compounds applied to excised queen and worker mandibular glands, using gas chromatography-mass spectrometry (GC-MS), Plettner *et al.*⁹ have proposed the following caste-specific, bifurcated three step biosynthetic pathway for the production of these compounds (Figure 2).

A caste-specific pheromone biosynthetic pathway

The starting point is stearic acid, a very common, 18 carbon, straight chain saturated intermediate of lipid oxidation¹⁰. In the first step of the proposed pheromone biosynthetic pathway, functionalization is achieved by the addition of a hydroxyl group on either the 18th (ω) or the 17th ($\omega-1$) carbon atom. This functionalization which foreshadows the queen-worker differences depending on whether it happens at the ω or the $\omega-1$ carbon atom is, however, itself not caste-specific; both ω and $\omega-1$ functionalizations occur in both castes to about the same extent. In the second step, the 18-carbon hydroxy acids are shortened to give 10-HDA and 9-HDA by the standard chain-shortening cycles of β oxidation that normally occur during fatty acid metabolism. It is the β oxidation step that is caste-specific – queens preferentially channel the $\omega-1$ compounds and workers preferentially channel the ω compounds into the β oxidation pathway. In the final step, oxidation of the ω or $\omega-1$ hydroxy group that was added in the first step, results in the formation of the diacid in the case of workers and the keto acid in the case of queens. The evidence for every feature of the proposed pathway is clear and convincing. Labelled stearic acid is incorporated into the final products but labelled palmitic and decanoic acids are not. There is no isomerization between 10-HDA and 9-HDA. Both the ω and $\omega-1$ functionalized hydroxy acids are detected to the same extent

Figure 2. The caste-specific, three-step, bifurcated pathway for the biosynthesis of queen and worker pheromones, as proposed by Plettner *et al.*⁹

in both castes but the subsequent steps are entirely caste-specific. That functionalization precedes β oxidation is evident from the fact that hydroxy acids with more than 10 carbons accumulate when an inhibitor of β oxidation, 2-fluorostearic acid is added to the reaction mixture. Thus both workers and queens add hydroxy groups to either the ω or the $\omega-1$ carbon atom but workers then preferentially convert the ω functionalized compound to produce 10-HDA and the corresponding diacid while the queens preferentially convert the $\omega-1$ functionalized compound to produce 9-HDA and the corresponding keto acid, 9-ODA. Since 9-ODA is the major component of the queen pheromone, I am tempted to dramatize and say that the essence of royalty is just one keto group!

Plettner *et al.*, however, merely conclude modestly from these remarkable findings that 'These results demonstrate how, in a social insect, caste-determined biosynthesis of isomeric compounds can produce markedly different glandular blends that are responsible for many functional differences between queens and workers.' In addition to the dramatization of the essence of royalty as one keto group, I believe that these results permit two other speculations of the considerable significance for our understanding of social evolution.

A chicken and egg problem

The first speculation concerns the usual chicken and egg problem – who came first, the queen or the worker? On the one hand, queens in social insect species can be thought of as being comparable to the undifferentiated

(into queen or worker) adult insects in their solitary ancestors (or, equivalently, in other extant solitary taxa) and the workers can be thought of as being a new invention of sociality. After all, adults in solitary species are all potentially capable of reproducing and it is the character of being sterile and merely working to rear another individual's brood, that is a novel feature of social insects. On the other hand, workers in social species may be thought of as being comparable to their solitary ancestors or extant solitary counterparts and the queens can be thought of as an invention of sociality. After all, adults in solitary species are all capable of nest building, foraging and brood rearing and it is the character of inhibiting reproduction of conspecifics and attempting to become the sole reproductive in a group, at the cost of losing foraging and brood-rearing abilities altogether if necessary, that is a novel feature of social insects. A reasonable solution to this conundrum is to compromise and think of the solitary insects as queen and worker combined because each individual is capable of reproduction as well as nest building, foraging and brood care. And this is a largely correct solution because both queens and workers, at least in the advanced social species, are considerably modified and exaggerated in their respective roles compared to solitary insects. Nevertheless, I believe that, if and when possible, we should try to make an objective assessment of whether queens are ancestral and workers are derived or whether workers are ancestral and queens are derived. I will argue that the pheromone biosynthetic pathway elucidated by Plettner *et al.*⁹, provide one such opportunity.

I hypothesize that the pheromone biosynthetic pathway employed by the workers deviates relatively little from the typical lipid metabolism pathway and is perhaps simply adopted from there. The diacid they make can relatively easily be channeled into an energy-generating role and its degradation products can be profitably fed into the Krebs's cycle. On the other hand, I speculate that the pheromone biosynthetic pathway of the queens is quite a deviation from the standard lipid metabolism pathway. In particular the keto acid is not something one would expect if energy generation is their goal. The expense involved in further breaking down the keto acid makes it a poor candidate to be fed into the Krebs's cycle. I therefore speculate that in the course of making their pheromones, the workers are doing more or less what any solitary insect would do anyway for generating energy from lipids and that their pheromone biosynthetic pathway is therefore the more ancestral one. Conversely, queens have considerably modified the ancestral lipid metabolism pathway in order to make a pheromone that has only lately (relatively speaking) become necessary. In order to do so, they are prepared to make an end product such as the keto acid which is energetically unwise but I argue that energy generation is not their motivation here. Surely they have other mechanisms of generating energy even from lipids. Even if their overall efficiency of generating energy from lipids is lower than that of workers, it does not matter that much because it is the foragers, not the queens, that have to fly great distances in search of food. The pheromone biosynthetic pathway of the queens appears therefore to be relatively more derived. One might also argue that the function of the worker pheromone namely, to act as a preservative and nutrient is also a more ancestral function, more likely to have been useful in the solitary condition. Conversely the function of the queen pheromone appears to be more derived as it fulfills a relatively more recent requirement and hence is unlikely to have been of much use in the ancestral solitary condition. Workers thus seem to use an ancestral biochemical pathway to make a product that may also have been required in the ancestral condition. And queens seem to be using a rather derived form of the biochemical pathway to make a product that has a rather derived function. At least in this limited context, workers seem to be ancestral and queens seem to be derived. This one context, important as it is, cannot be thought to have solved our general problem of who came first, the queen or the worker. It would be prudent, even necessary, to be on the look out for more opportunities to classify queens and workers as ancestral or derived. Indeed, a new and highly derived function of the worker pheromone may yet be discovered which may alter our conclusion. Thus, we may well come up with different conclusions each time and only the relative scores for 'ancestral' and 'derived' that queens and workers accu-

mulate in the long run can help us solve this conundrum in any general sense. But I believe this is a good beginning.

The evolution of caste polymorphism

Yet another striking feature of the social insects, the highly social insects in particular, is the morphological differentiation of queens and workers which may sometimes reach such proportions that, if encountered separately, queens and workers may get classified as different species¹¹. The greatest intra-specific size variations have been recorded in the Asian ant *Pheidologeton diversus*, where some workers weigh 500 times and have a head width 10 times compared to other workers¹². Here the differentiation is not between queens and workers but between the so-called major workers and minor workers. Whether it is between queens and workers or between major and minor workers, these extreme degrees of intra-species, intra-sexual dimorphism require an explanation. The fact that no solitary species seem to match these levels of differentiation suggest that the explanation is linked to the social habit of these insects.

I have recently offered a speculation¹³⁻¹⁵ which was inspired by the idea of evolution by gene duplication first suggested by Haldane¹⁶ and Muller¹⁷ and elaborated and championed by Susumu Ohno¹⁸. The idea is that redundant, duplicate copies of genes can accumulate potentially lethal mutations without killing the organism and eventually can give rise to novel genes coding for novel structures via pathways that would be inaccessible to an individual with a single copy of the gene. I have argued that a very similar consequence will accrue to social insects although for a somewhat different reason. The evolution of altruistic sterile worker castes in the social insects was considered paradoxical until Hamilton proposed the theory of inclusive fitness¹⁹. Today it is common practice to recognize inclusive fitness as having two components, a direct component gained through production of offspring and an indirect component, gained through aiding close genetic relatives. Sterile worker castes are expected to gain fitness exclusively through the indirect component^{4,20,21} and in no other group is there a comparable level of dependence on the indirect component of inclusive fitness.

When some individuals in a species begin to rely on the indirect component of inclusive fitness while others continue to rely on the direct component, as workers and queens in social insects are expected to do, I have argued that different sets of genes in queens and workers will be liberated from previous epistatic constraints and become free to evolve in new directions, because the same individual no longer has to optimize both reproductive and non-reproductive functions. There is no gene duplication here in the conventional sense but the

consequence namely, liberation from previously existing constraints (due to the action of stabilizing selection) and the opportunity to diversify in different directions (through the action of directional selection), is similar. To put it simply, an individual can evolve into a 'super' egg layer if it does not also have to simultaneously be a good forager or it can evolve into a 'super' forager if it does not also have to simultaneously be a good egg layer.

I wish to speculate now that compared to solitary species, social insects are also in a better position to exploit the evolutionary advantages of conventional gene duplication. I have argued in the previous section that the function of the worker pheromone and the biochemical pathway involved in its production are relatively more ancestral and that the function of the queen pheromone and the biochemical pathway involved in its production are relatively more derived. If this is true, it is not difficult to see the tremendous advantage of conventional gene duplication in bringing about the derived condition from the ancestral one. It seems likely that the enzymes involved in the β oxidation step (Figure 2) give rise to specificity for substrates hydroxylated at the ω or $\omega-1$ positions. Imagine that the ancestor of the social insect species had a gene that coded for an enzyme which could deal only with the substrate that was hydroxylated at the ω position. The workers in the descendant social species can continue to use this gene and this enzyme to make worker pheromones which may perhaps have even been made by the ancestor. A duplication of the gene involved can permit the evolution of an alternate enzyme which can handle the substrate hydroxylated at the $\omega-1$ position. We know that such a substrate must already have been available because both kinds of hydroxylations occur to an equal extent in both queens and workers. The duplicated gene would now be free to evolve in new directions without reduced fitness due to the reduction in the efficiency of energy production through lipid metabolism. And new directional evolution can sometimes give rise to substances with such remarkable properties as those of the queen pheromone. A similar chance occurrence of such evolution could hardly have been utilized effectively by a solitary species. Because social insects set aside some individuals for the sole purpose of monopolizing reproduction and inhibiting and controlling all others, they are in a special position to exploit such a consequence of conventional gene duplication.

Evolutionary biologists have often found it useful to clearly distinguish between proximate physiological explanations and ultimate evolutionary explanations. Indeed, failure to make this distinction has sometimes led to unnecessary confusion as to what constitutes a valid answer to the question of why an animal does what it does. However it would be unfortunate if we permanently

delink the study of proximate mechanisms and ultimate evolutionary explanations²². The biochemical pathway for the caste-specific biosynthesis of pheromones elucidated by Plettner *et al.*⁹, constitutes an excellent illustration of how our understanding of the proximate and ultimate factors can mutually reinforce each other. It is high time, that evolutionary biologists became biochemists and vice versa!

Realtime kinetic analysis of antigen–antibody interaction using solid phase binding: Transformation of hCG-monoclonal antibody complex

G. S. Murthy

Primate Research Laboratory, Centre for Reproductive Biology and Molecular Endocrinology, Indian Institute of Science, Bangalore 560 012, India

Kinetic constants of MAb–hCG interactions have been determined using solid phase binding of $^{125}\text{I}[\text{hCG}]$ to immobilized MAb. While association has been shown to follow the expected pattern, dissociation consists of at least two reversible steps, one with a rate constant of 0.0025 min^{-1} , and a second with a rate constant of 0.00023 min^{-1} . Validity of affinity constant measurements in the light of the complex reaction kinetics is discussed. A comparison between the method of surface plasmon resonance technology (BIAcore) and solid phase binding (SPB) for determination of kinetic parameters shows that SPB provides not only a cost-effective approach for determination of realtime kinetic parameters of macromolecular ligand–ligate interaction but also a method with several advantages over the BIAcore system in investigating the mechanism of antigen–antibody interaction.

ANALYSIS of ligand–ligate interaction has found renewed surge of interest with the development of surface plasmon resonance technology to study realtime kinetics of the interaction with BIAcore^{1–5}. Using this approach kinetic constants have been determined for several ligand–ligate pair, most common being MAb–antigen pair. Several kinetic and thermodynamic constants obtainable by the BIAcore can also be obtained, in theory, by radiolabelled ligand binding to MAbs in conventional approach like liquid phase RIA (LPRIA), enzyme-linked immunosorbent assay (ELISA), etc. However this simple approach has not been seriously attempted in the past, probably for the following reasons. First, extensive use of ELISA, in most of the MAb-related research, was the method of choice for study. However attempts to use ELISA for determination of even simple equilibrium constant were inconsistent^{6–12}. Other alternate method, namely LPRIA with MAbs is cumbersome for kinetic studies with radiolabel being an added deterrent. In addition, as has been shown by us recently, both the methods LPRIA & ELISA are multistep processes and suffer from post-equilibrium disturbance, due to easy dissociability of the MAb–Ag complex^{13,14}. Develop-

ment of single step solid phase assay using immunochemically adsorbed antibodies allows instantaneous termination of the reaction at equilibrium, and hence, eliminates uncertainties that exists in ELISA/LPRIA¹⁵. Thus binding of radiolabelled antigen to immobilized MAbs provides a method by which kinetic analysis of antigen–antibody interaction can be investigated. In the following we determine the kinetic constants of the reaction and analyse dissociation pattern of MAb– $^{125}\text{I}[\text{hCG}]$ complex and discuss results in the light of BIAcore analysis.

Materials and methods

Human chorionic gonadotropin (hCG) was prepared from early pregnancy urine and characterized as reported earlier¹⁶. Iodination grade hCG was obtained from NHPP, Bethesda, USA. MAb VM4 was raised in our laboratory by a standard procedure using hCG $\alpha\beta$ dimer for immunization. This MAb was found to be specific for the native β subunit and reacted well with the dimer.

Iodination of hCG was carried out by iodogen method¹⁷. Specific activity was calculated by the extent of incorporation. Unless otherwise stated, the specific activity was 45,000 cpm/ng hormone. Freshly prepared $^{125}\text{I}[\text{hCG}]$ was used in all kinetic experiments.

Scatchard plot analysis

MAb was immobilized through immunochemical bridge on microtiter wells as already described^{13–15}. MAb VM4 culture fluid was coated at a dilution of 1/1000 for SPRIA. SPRIA was carried out by the standard procedure and the data was subjected to Scatchard analysis to obtain apparent affinity constant¹⁸ (K_a).

Determination of association constant

$^{125}\text{I}[\text{hCG}]$ was added to VM4-coated wells (coated with 250 μl of 1/50 VM4 culture fluid) and binding was ter-

RESEARCH ARTICLES

minated at different periods of time by washing the wells with RIA buffer. Radioactivity bound to the wells was monitored and used for determination of the rate constant by the following formula.

$$k_{+1} = [dx/dt]/[Ag] \cdot [MAB],$$

where dx/dt represents the slope of the binding data, $[Ag]$ and $[MAB]$ represent the initial concentrations of antigen and antibody, all expressed in moles/litre.

Determination of dissociation rate constant of hCG-VM4 complex

$^{125}\text{I}[\text{hCG}]$ was bound to immobilized MAb overnight, washed and counted in a multigamma counter. Dissociation was started immediately by adding 250 μl of hCG (2 $\mu\text{g}/\text{ml}$) in 0.05 M phosphate buffer, pH 7.0

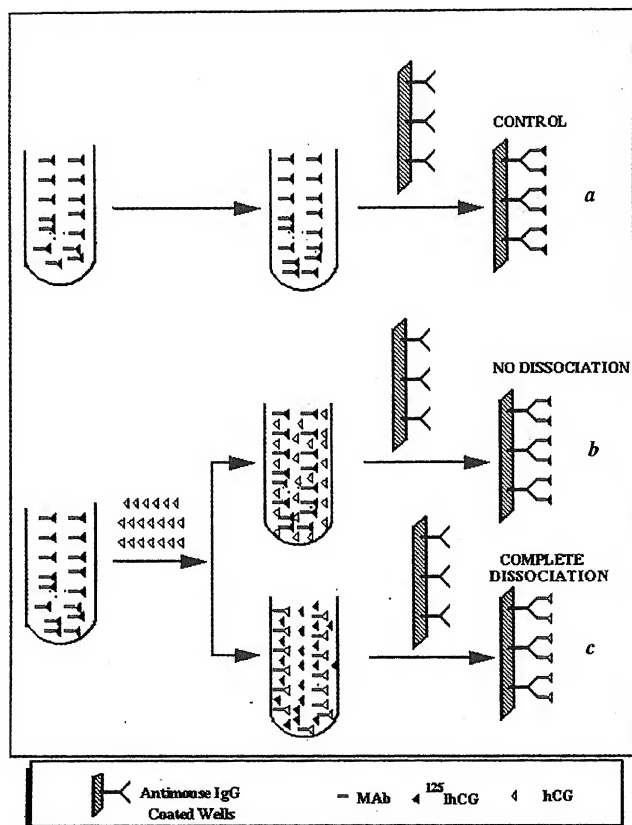

Figure 1 a-c. Schematic representation of the dissociability of $^{125}\text{I}[\text{hCG}]$ -VM4 complex in liquid phase (a) control. (b) and (c) show the situation when the $^{125}\text{I}[\text{hCG}]$ -MAb complex is completely non-dissociable or completely dissociable. In a completely dissociable situation, the binding of the complex formed in the liquid phase to the Mouse DAb coated well will be nonspecific (c), while in the case of complete nonreversibility it will be like specific binding (b) as in the control (a). Intermediate values present partial reversibility (See methods for experimental details).

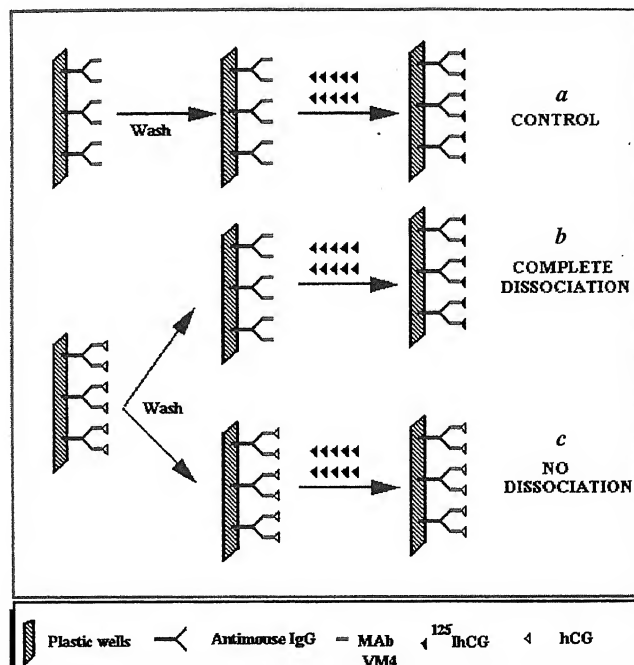

Figure 2 a-c. Schematic representation of the dissociability of hCG-VM4 complex from the solid phase (a), binding of $^{125}\text{I}[\text{hCG}]$ to VM4 coated well (control). (b) and (c) show sequence of events when the VM4-hCG complex dissociates completely or does not dissociate. Complete dissociation results in binding of $^{125}\text{I}[\text{hCG}]$ comparable to control (a) and lack of dissociation results in nonspecific binding (c). Intermediate values present partial dissociation (See methods for experimental details).

containing 2% bovine serum (RIA buffer). At known intervals of time, the supernatant was discarded and the radioactivity bound was measured in the same carrier of the multigamma counter as done before (this is to take care of different counting efficiencies of the carriers). Radioactivity measured at each point of time is expressed as percentage of the radioactivity retained by the well¹⁹. For determining the dissociation rate constants plot of $\ln[(a-b)/(x-b)]$ vs time was drawn from the data. Value of a was 90%, while that of b was 48% for fast dissociation rate constant (x was taken between 0 and 400 min for the fast dissociation), while for the slow dissociation they were 48% and 0% respectively (x values taken for 13 h, 24 h and 48 h: see under results for details).

Capacity measurement of the well

Capacity of the well to bind hCG was measured by specific binding, specific activity of the $^{125}\text{I}[\text{hCG}]$ and K_a determined by Scatchard plot using the formula

$$C_{\text{MAb}} = [B/F + K_a \cdot B] \cdot [1/K_a],$$

where B and F represent bound and free antigen concentrations, C_{MAB} represents the capacity of the well and K_a affinity constant. This method is routinely used for determination of the concentration of MAb required for rate constant measurements.

Determination of apparent nonreversibility

In liquid phase. The rationale of the approach is shown in Figure 1. Experimentally, $^{125}\text{I}[\text{hCG}]$ (200,000 cpm) was incubated with VM4 antisera in the liquid phase in a tube for 1–2 h at room temperature. 100 μl of the $^{125}\text{I}[\text{hCG}]$ -VM4 complex (100,000 cpm) is added to immobilized antimouse IgG (in microtiter wells) and binding carried out for 2–4 h at room temperature. As control, the same amount of $^{125}\text{I}[\text{hCG}]$ (100,000 cpm) incubated in RIA buffer was added. Radioactivity bound to the wells is a measure of the extent of nonreversibility.

In solid phase. Figure 2 schematically represents the methodology of the experiment (see legend for details). Immobilized VM4 on plastic wells was saturated with hCG by incubating with 2 $\mu\text{g}/\text{ml}$ hCG for 20 h. Unbound hCG was washed off and hCG bound to the antibody was incubated with RIA buffer (250 μl) for 2 h to allow dissociation to occur. The wells were washed, further dissociation allowed to occur for an additional ten times. Finally $^{125}\text{I}[\text{hCG}]$ (100,000 cpm, 250 μl) was added to the well and after 20 h incubation period the radioactivity bound was measured in a LKB multigamma counter. As control VM4 adsorbed wells were also washed with RIA buffer the same number of times, except they were not saturated with hCG. Difference between the specific binding of these two sets gives an index of the extent of nonreversibility.

Determination of affinity constant

By Scatchard plot. Affinity constant was obtained by the standard method already described.

From re-equilibrium data. $^{125}\text{I}[\text{hCG}]$ (250 μl , 100,000 cpm) was added to immobilized VM4 and specific binding after 20 h incubation was determined (S). To each of the wells was added 250 μl of RIA buffer and re-equilibration of the $^{125}\text{I}[\text{hCG}]$ allowed to occur between the solid phase and solution phase for 20 h at room temperature, supernatant discarded and radioactivity bound was measured (B). Another set of wells were incubated overnight with 250 μl of 2 $\mu\text{g}/\text{ml}$ hCG. Radioactivity that remained bound to this was taken as 'apparently nondissociable' $^{125}\text{I}[\text{hCG}]$ from the complex (N). From this data K_a was calculated by the formula

$$K_a = [B - N] / [S - B] \cdot [(C_{\text{MAB}} - N) - (S - B)],$$

Figure 3. SPRIA and K_a determination by Scatchard and single point binding. Inset shows Scatchard plot for the displacement analysis.

Figure 4. Determination of k_{+1} by binding data: $^{125}\text{I}[\text{hCG}] = 112,000 \text{ cpm/well}$ of specific activity $26,000 \text{ cpm/ng}$ added to VM4 coated wells at 0 time. Capacity of the MAb adsorbed calculated from overnight binding was $5.193 \times 10^{-10} \text{ M}$ and that of $^{125}\text{I}[\text{hCG}]$ $4.657 \times 10^{-10} \text{ M}$ respectively (see for details under methods). Affinity constant taken for calculation is $3 \times 10^9/\text{M}$, obtained from the data of Figure 3.

RESEARCH ARTICLES

where all values are expressed in concentrations (moles/litre). C_{Mab} is the concentration of the MAb immobilized on the well, obtained from overnight binding data as explained earlier.

From rate constants. Forward rate constant (k_{+1}) and reverse rate constant/s (k_{-1}) determined as described above have been used to derive K_a by the formula

$$K_a = k_{+1}/k_{-1}.$$

Results

Scatchard plot analysis of SPRIA using immobilized VM4 for the determination of apparent affinity constant gave a value of $3 \times 10^9 \text{ M}^{-1}$ (Figure 3). Affinity constant measured by single well binding also gives comparable results¹⁹. Hence in all further experiments concentration of bound MAb is calculated from single point binding data as explained under methods.

Binding of $^{125}\text{I}[\text{hCG}]$ to immobilized VM4 with time is linear (Figure 4). Rate constant of association measured using the slope of this plot is $8 \times 10^6 \text{ M min}^{-1}$. This is comparable to that obtained in several MAb–Ag pair using the BIAcore method^{20–22}.

In contrast to the association profile which follows a linear pattern, dissociation profile of the $^{125}\text{I}[\text{hCG}]$ –

Figure 5. Dissociation profile of bound $^{125}\text{I}[\text{hCG}]$ –Mab complex: $^{125}\text{I}[\text{hCG}]$ (86,000 cpm of specific activity 42,000 cpm/ng, 250 μl) was added to microtiter wells previously coated with Mab VM4 at 1/100 dilution for overnight binding (cpm bound = 35876 ± 2918), and dissociation started by adding 250 μl of unlabelled hCG (200 ng/well). Inset shows the extent of retention of binding for extended periods of incubation (13 h to 48 h).

Figure 6. Plot for determination of dissociation rate constant. Extrapolated binding to 0 time is considered (52%) as maximum dissociable for the determination of the fast rate of dissociation ($a = 90$, $b = 48$). Right panel shows the 'dissociation rate constant' obtained for the slow dissociation with $a = 52$, and $b = 0$ (See under methods for details).

Table 1. Dissociation of the $^{125}\text{I}[\text{hCG}]$ –VM4 complex in liquid phase binding ($^{125}\text{I}[\text{hCG}]$ bound to VM4 coated wells in cpm)

VM4 dilution used during complex prepn	Non sp.* control	Exptal	Sp. control	% non-reversible
1/400	1845	12,300	33,212	37
1/800	1300	12,500	28,500	43
1/1600	908	8,150	19,800	40
1/3200	520	4,700	12,800	37

*This control presents the $^{125}\text{I}[\text{hCG}]$ incubated with VM4 in the presence of 2 $\mu\text{g/ml}$ hCG. Exptal represents $^{125}\text{I}[\text{hCG}]$ incubated with VM4 in absence of unlabelled hCG (overnight) to which 2 $\mu\text{g/ml}$ hCG was added and reequilibrated (120 min) before adding to immobilized Dab. Sp. controls represent binding of $^{125}\text{I}[\text{hCG}]$ VM4 at respective concentrations to immobilized Dab (Antimouse IgG).

Mab is more complex. Even after 8 h of incubation with excess unlabelled hCG complete dissociation of the complex does not occur (Figure 5) with further dissociation occurring rather slow but certain (inset), indicating two distinct rates of dissociation, and the two rate constants of dissociation are 0.0025 min^{-1} and 0.00023 min^{-1} respectively (Figure 6). The first rate constant (k_{-1}) is obtained by assuming the total dissociable $^{125}\text{I}[\text{hCG}]$ to be 52% based on the extrapolated

Table 2. Dissociability of hCG-VM4 in solid phase

	Binding of radioactivity to immobilized VM4 (<i>n</i> = 7) cpm \pm SD
Control [Binding of ^{125}I [hCG] to immobilized VM4 well]	50,400 \pm 3650
Experimental [Binding of ^{125}I [hCG] to immobilized VM4, saturated with hCG and extensively washed for complete dissociation]	33,519 \pm 3000

Figure 7. Increase of slowly dissociable portion (transformed complex) of preformed complex of VM4- ^{125}I [hCG]. Radioactivity bound at 1 h incubation period (0 time of dissociation) was 16,450 \pm 540 (SD) cpm. Unbound ^{125}I hCG was discarded and dissociation started at time periods as indicated in X-axis.

slow dissociation data (curve in the inset of Figure 5 extrapolated to 0 time) while the second rate constant (k_{-2}) is obtained by assuming that the slow dissociation is complete in due course, and analysing the points above 8 h by which time most of the fast dissociation is complete.

Dissociation observed in the above solid phase method is not an artifact arising out of iodination of hCG or because of solid phase binding has been proved by demonstrating that reaction of the MAb with ^{125}I [hCG] in liquid phase is as much 'nondissociable' as

in the solid phase (Table 1). The extent of slow dissociability seen is about 40%, comparable to that obtained in SPB (35%). Similarly VM4 saturated with unlabelled hCG in the solid phase does not completely dissociate in spite of a dozen washings (Table 2) and rules out slow dissociation as an artifact arising out of labelled hCG. Apparent nondissociable portion of the binding increases linearly with time (Figure 7) in absence of either of the reactants. This increase is quite significant going up to 50% in 8 h. However incubation of this complex with unlabelled hCG slowly releases the ^{125}I [hCG] into medium, indicating this apparent nondissociation to be infact a slow dissociation. The result also indicates that this transformation appears to be spontaneous, as it occurs in the absence of any other reactants.

On the basis of these kinetic evidences, the mechanism of MAb-hCG interaction can be presented as follows to account for the rate constants.

where Ag-Ab and Ag-Ab* present dissociable and transformed complex respectively. Conversion (apparent dissociation) rate constant of Ag-Ab* to Ag-Ab is about 10% compared to the dissociation rate of Ag-Ab to Ag and Ab. This proposed mechanism is for MAb VM4, but is likely to be true for other epitope-paratope pairs. Relevance of this slowly transformed Ag-Ab* in physiology also needs to be studied further. Apparent nonreversibility of several polyclonal antibodies clearly indicates that such transformed species are present in polyclonal antisera-antigen complexes and hence may have relevance in physiological systems.

On the basis of these studies, there are several ways to obtain affinity constants of VM4- ^{125}I [hCG] interaction. It is certain that K_a as determined by Scatchard plot, though extensively used, may not quantify avidity of the system. A comparison of affinity constants measured for this system using different methods shown in Table 3 demonstrates that the affinity constants measured are not very different from Scatchard plot data. However caution should be exercised in the choice of the disso-

Table 3. Affinity constant measurements by different methods (M^{-1})

Scatchard plot from SPRIA	3.00×10^9
By single well binding	2.97×10^9 (<i>n</i> = 6)
By reequilibration data	6.60×10^9 *
By k_{+1}/k_{-1} (using fast dissociation)	3.33×10^9 **
By k_{+1}/k_{-1} (using slow transformation)	33.30×10^9 ***

*Input ^{125}I [hCG] = 86,000 cpm, bound overnight = 59,000 cpm, nondissociable by 48 h incubation with hCG = 9500 cpm, ^{125}I [hCG] bound after overnight reequilibration in 250 μl of RIA buffer = 29,200 cpm.

**Using k_{+1} of $0.8 \times 10^7 \text{ min}^{-1}$ and k_{-1} of 0.0025 min^{-1} .

***Using k_{+1} of $0.8 \times 10^7 \text{ min}^{-1}$ and k_{-2} of 0.00023 min^{-1} .

ciation rate for the calculation of the K_a , because slow transformation is an integral part of the binding reaction.

Discussion

Reaction kinetics have been investigated in several systems using radioligands. Unsuccessful attempts of the same approach with antigen-antibody interaction can be traced to the error of the analytical tool that was adopted, namely ELISA and LPRIA. Both are multistep assay systems, and during post-equilibration period reversibility of MAb- $^{125}\text{I}[\text{hCG}]$ has been clearly demonstrated to introduce errors in interpretation¹³. Solid phase binding (SPB), a single step method, which eliminates the errors arising out of reversibility has made it possible to investigate the kinetic parameters.

Results presented clearly demonstrate that kinetic constants can be measured using binding of radiolabelled ligand to MAb adsorbed immunochemically to plastic wells. Binding of $^{125}\text{I}[\text{hCG}]$ to immobilized matrix follows a second order reaction as expected with a measurable rate constant which falls in the range of the data generated for several MAb-Ag pairs using the BIAcore system. Contrary to expectations, dissociation in presence of 1000-fold excess of hCG is not complete though it follows a first order reaction with measurable rate constant, and 35% of the radiolabel remains bound to the well even after 20 h of incubation. Also, this apparent nondisplaceability is not artifactual arising out of iodination of the hCG, as nondissociability is seen in solid phase binding of unlabelled hCG (Table 2). In fact immobilized MAb-hCG (saturated with unlabelled hCG) after repeated washing fails to bind $^{125}\text{I}[\text{hCG}]$ to the same extent as free immobilized MAb (Table 2), and clearly demonstrates that partial nonreversibility is indeed true in both solid and liquid phases even when using nonradioactive ligand. Though the extent of nondissociability is 30% with VM4, several antibodies show as much as 50–80% nondissociability, and hence indicate its significance.

Based on the two step pattern of dissociation, a reversible one and the second slow-reversible one, reaction of an MAb with $^{125}\text{I}[\text{hCG}]$ can be presented as in (eq. 1). First step promoted by epitope-paratope interaction leads to a complex (Ag-Ab), which is in reversible equilibrium with free antigen and antibody; second step consists of its transformation to another complex (Ag-Ab*). One of the immediate questions this complex dissociation data projects is the validity of affinity constants extensively employed as a quantitative measure of avidity. Affinity constants measured by different methods tabulated show that it is not significantly different. Scatchard value is similar to that obtained by individual rate constant determinations representing the first step of the reaction. However affinity constants as measured

from re-equilibrium results (Table 3) are also comparable though on the higher side. Considering that in this case the extent of nonreversibility is 30%, K_a measured by all the methods are comparable. If nondissociability were to be 50–80% as it happens in some MAbs, the measured K_a considering the nondissociable portion could be different from that obtained by direct Scatchard measurements/binding data/ $[k_{+1}/k_{-1}]$ measurements. The nondissociability data indicate that caution is needed in assessing K_a by Scatchard plot, and in adopting appropriate methods for relative measurements. An absolute measure of K_a is unlikely to be determined from binding data methods, like Scatchard plot, single well binding, etc. Infact affinity constant needs to be redefined to the requisite step of the reaction.

Analysis of the dissociation data points to transformation of the primary Ag-Ab complex to a transformed (slow-dissociable) Ag-Ab* type (Figures 6, 7). The chemical or physicochemical events which lead to this are not known presently. This is not associated with a covalent binding of MAb-hCG is certain as 5% formic acid completely dissociates the radiolabelled hCG instantaneously (data not shown). How the transformation is related to epitope-paratope interaction is also unclear. Likewise physiological significance of the transformed complex is unknown.

Analysis of the kinetics of dissociation shows that the reaction of an antigen with its antibody is not a simple epitope-paratope reaction and the mechanism proposed here is a minimal requirement. While kinetically the mechanism of the reaction can be presented as shown in eq. (1), additional chemical data is needed to investigate the nature of the reaction. But, it is certain that the interaction of antigen-antibody though promoted by epitope-paratope pair may have other components which are unknown. The regions involved in subsequent conversions are not known, but definitely it is not promoted by the presence of either hCG or Mab (Figure 7).

There are two other methods reported which can measure kinetic constants of MAb-Ag reaction – the BIAcore method which uses surface plasmon resonance^{1-5,20-23}, and the method of Larvor *et al.* using liquid phase reaction coupled to ELISA for determination of dissociation rate constant²⁴. Presently, the former method is used widely because of the ease of determination and the rapidity with which results can be obtained. The method used in this paper (SPB method) is comparable to the BIAcore method in that both are heterogeneous reaction systems where one of the ligands is immobilized. Moreover, association and dissociation constants can be determined by both the methods. Comparisons between these two systems are illustrated in Figure 8. The top panel shows diagrammatically the flow-cell of a BIAcore having dimensions of $50 \times 500 \times 2000 \mu\text{m}$. Flow of solutions is through the

Figure 3. Schematic comparison of the flow cell of BIAcore (top panel) and plastic surface of SPB (lower panel). Arrows show the direction of flow of the solvent in flowcell of BIAcore. ■ presents immobilized ligate covalently bound to the flow cell (in BIAcore) or adsorbed immunochemically (in SPB). Numbers (in μm) represent the dimension of the flow cell, while the corresponding numbers in the brackets represent the number of molecules of the ligate bound along the corresponding axis. Total number of molecules bound in the BIAcore flow cell is about 20×10^{10} molecules. Note that the ligates are stacked up within the flow cell in three dimension, while in the SPB (lower panel) it is distributed in two dimension only.

Table 4. Molecular distance between immobilized antibody molecules in BIAcore cell and in plastic well

(b) RU of 10,000	$7.2 \mu\text{M}$	60 nl	$5.5 \times 10^{-2} \mu\text{m}$

*Taken from Hall *et al.*²⁶.

cross-section of ABCD shown by the arrow. The flow-cell has immobilized ligate in space in multilayers illustrated by small squares. Distance between each ligate in

both BIAcore and SPB (bottom panel) is about $6 \times 10^{-2} \mu\text{m}$, almost 10–50 molecular distances apart from each other (Table 4). Thus both the systems have the same molecular disposition of the ligates, and are subject to similar criticisms on these grounds. While immobilization is done through covalent binding in BIAcore, immunochemical bridge has been used in the SPB method. By the nature of the immobilization of ligates each method has its advantages. Two assumptions made in analysis of the results from BIAcore have been that association is not diffusion controlled and dissociation is not complicated by rebinding of the dissociated ligand. Both the assumptions have been questioned^{25,26} and the nature of the problem can be illustrated with Figure 8. In dissociation, which starts with saturated ligand, the solute enters the cells at the cross-section ABCD traverses through and exits at EFGH cross-section. As can be seen in the Figure the dissociated ligand at the cross-section near ABCD has to pass through a very large number of molecules of the immobilized ligate (in this case about 17×10^{10} molecules) which allows rebinding of the dissociated ligand. This error is rather small in early stages of elution (5–10 s by which time about 10 volumes of the solvent has flown through), but tends to become more and more as dissociation increases, effectively distorting the dissociation pattern much like in chromatography and underestimates the true dissociation rate. This effect has been demonstrated by Nieba *et al.*²⁵, and becomes highly significant if the association constant is of the order of 10^5 M s^{-1} , a range common in most MAb–Ag systems^{20–23}. Similarly if the association constant of the ligand is very high [$>10^7 \text{ M s}^{-1}$] binding is limited by diffusion rather than the binding constant. This is especially so because the ligate is embedded in dextran matrix in three dimension and hence diffusion is an obligatory first step in the binding. Methods have been recently suggested to overcome these problems, but the corrections to be adopted require good knowledge of kinetics, and are unlikely to be the same for all the ligand–ligate pair. In contrast to BIAcore, SPB method utilizes the ligate immobilized on a single surface (Figure 8, lower panel) and does not suffer from the disadvantage of reassociation. Since the ligate is fixed as a monolayer, free access of the ligand to the ligate exists, and hence does not impose a limitation based on diffusion as in the BIAcore. Thus these two major problems associated with BIAcore do not exist with the SPB. Complex dissociability pattern, which has not been quantitated so far in the BIAcore, can be quantitated by the SPB method. Apparent nonreversibility present in protein–protein binding is clearly demonstrated in the dissociation patterns in the BIAcore approach as well, but mostly neglected in all interpretations^{20–22}. Quantitation of slow dissociation throws light on the mechanism of ligate–ligand interaction better through kinetic approach. In contrast to these advantages of the SPB

RESEARCH ARTICLES

method, need of radiolabelled ligand is a disadvantage needing pure antigen for investigations and a need to prove that the results obtained are not artifactual arising out of iodination. However the results presented here indicate that they are not artifactual and are likely to be the same for all other ligand–ligates. Quantum of the ligate that can be incorporated into the flowcell of BIAcore is 1000-fold more than in the SPB method, which makes it possible to investigate low affinity binding [$\times 10^5/M$] using BIAcore while the affinity of the ligand–ligate should be high [$\times 10^7/M$] for the SPB method.

Though data presented here are for the antigen–antibody pair, the approach is not limited to only this ligand–ligate pair, or to only radioiodine-labelled antigens. The same approach can be used to study other important ligand–ligate pair like that of protein–RNA, protein–DNA, etc. Demonstration of transformation of reversible Ag–Ab complex to slow-dissociable complex (Ag–Ab* type) indicates the possibility that such as yet unrecognized interactions may also be present in other ligand–ligate pair. Thus the SPB method provides a very cost-effective approach to study the realtime kinetics of ligand–ligate interaction. Such studies may be expected to provide new valuable information on the interaction of macromolecular ligand–ligate pair. Importance of the transformed complexes in physiology/physiological processes needs to be investigated.

Liquid drops in rise against gravity through a viscous medium: Drag force by the method of dimensions and comparison with liquid drops in fall under gravity

G. J. Srinivasan*, P. Satyanarayana and G. Thirunavukkarasu

Physics Division, Forensic Sciences Department, Mylapore, Madras 600 004, India

*Department of Instrumentation and Control Engineering, Dr MGR Engineering College, Maduravoyal, Madras 602 102, India

We have presented previously the results observed in the study of liquid drops of Reynolds number (20–305), Eotvos number (2×10^{-2} to 105×10^{-2}) and Morton number (4.75×10^{-12} to 3.75×10^{-7}), in free fall without exhibiting oscillation through an immiscible liquid column where the liquid in the column is lighter than the liquid drops which tend to fall (downward motion) under the influence of gravity from the top of the liquid column. Suppose the column liquid is heavier, then, obviously, the motion of the liquid drop is completely curtailed and the drop floats. However, the motion of the drop may be achieved by its rise (upward motion) from the bottom of the liquid column. The rise of the drop occurs against (the influence of) gravity. The motion of the drop in rise against gravity may be thought or assumed to be opposite to that of the motion of the drop in fall under gravity. Therefore, we have devoted attention here to study the drops in rise against gravity through an immiscible liquid column to understand whether the expressions satisfying the drop in fall under gravity also hold good for the drop in rise against gravity or not and to determine the proportionality constant K of the drag force expression (eq. (1)) which suits the drop in rise against gravity and another constant S (eq. (6)) just as observed for drops in fall under gravity. In the present study, the drops in rise against gravity considered are in the range of Reynolds number, R_e (25–495), Eotvos number, E_t [(2×10^{-2}) to (70×10^{-2})] and Morton number, M_o [(2.06×10^{-12}) to (7.13×10^{-10})]. The important observations made in the present study are that (i) the value of the proportionality constant of the drag force expression for drop in rise against gravity differs from the value of the proportionality constant of the drag force expression for drop in fall under gravity and (ii) the value of the constant S in the case of drops in rise against gravity differs from the value of the constant S in the case of the drops in fall under gravity¹. For drops in rise against gravity, here, the predicted value for K and S are respectively 4.6082 (≈ 4.6) and 0.3176 (≈ 0.32) $m^{-1} s^2$; for drops in fall under gravity, they were predicted as $K = 3.6094$ (≈ 3.6) and $S = 0.2483$ (≈ 0.25) $m^{-1} s^2$.

RECENTLY Srinivasan and Satyanarayana¹ have presented the results observed in the study of liquid drops in the range of Reynolds number, R_e (20–305) ($R_e = \sigma u D / \eta$), Eotvos number E_t (2×10^{-2} to 105×10^{-2}) ($E_t = g \Delta \rho D^2 / \gamma$), and Morton number, M_o (4.75×10^{-12} to 3.75×10^{-7}) ($M_o = g \eta^4 \Delta \rho / \sigma^2 \gamma^3$), in free fall without exhibiting oscillation through an immiscible liquid column (column liquid is lighter than the drop). $\Delta \rho$ is the absolute value of density difference, $|\rho - \sigma|$. In their study¹, they obtained a fresh expression for the drag force by the method of dimensions for the drop in fall from the top of the liquid column under the influence of gravity. When the liquid drop is lighter, the motion of the drop occurs by rise from the bottom of the column against gravity. Since the motion of the drop in rise against gravity may be thought to be opposite to that of the motion of the drop in fall under gravity, an attempt has been made in this paper to study the rise of liquid drop against gravity without exhibiting oscillation through an immiscible liquid column by the method of dimensions and to arrive at results to know whether they are in line or not with the observations that were already made in the case of liquid drops falling without exhibiting oscillation under the influence of gravity¹ through an immiscible liquid column. Studies on the rise of liquid drops through an immiscible liquid column have been carried out by several authors^{2–28}. Literature review shows that none has attempted to deal with the problem of rise of liquid drops with only six variables F , D , u , η , ρ and σ in the dimensional analysis of the drag force F (F is the drag force acting on the drop in rise; D is the diameter of the drop; u is the terminal velocity attained by the drop; η is the viscosity of the liquid in the column; ρ is the density of the liquid drop; and σ is the density of the liquid in the column). Therefore these six variables F , D , u , η , ρ , σ alone are considered to arrive at an expression for the drag force (eq. (1)) acting upon the drop in rise against gravity without exhibiting oscillation through an immiscible liquid column by the method of dimensions. Since Srinivasan and Satyanarayana¹ have employed only these six variables to arrive at a fresh expression for the drag force acting on the drop in fall under gravity without exhibiting oscillation through an immiscible liquid column, an attempt has also been made to know whether the expressions (eq. (1)–(10)) given by them by the method of dimensions for drops in fall under gravity hold good for the drops here in rise, against gravity or not. Drops of Reynolds number, R_e (25–495), Eotvos number, E_t [from (2×10^{-2}) to (70×10^{-2})] and Morton number, M_o [from (2.06×10^{-12}) to (7.13×10^{-10})], which rise without oscillations against gravity through an immiscible liquid column are dealt with in the present study. The experimental data points predict 4.6082 (≈ 4.6) for the constant K of the drag force expression (eq. (1)) which suits drop in rise against gravity. The predicted value of K is

3.6094 (≈ 3.6) for drops¹ in fall under gravity. For drops in rise against gravity, the experimental data points here predict the value for the constant S as 0.3176 (≈ 0.32) $\text{m}^{-1} \text{s}^2$ which, for drops in fall under gravity has been predicted as 0.2483 (≈ 0.25) $\text{m}^{-1} \text{s}^2$ (ref. 1).

The experiments show that for drops (sufficiently small) in rise against gravity in the range of Reynolds number, R_e (from 25 to 495), Eotvos number, E_t [from (2×10^{-2}) to (70×10^{-2})] and Morton number, M_o [from (2.06×10^{-12}) to (7.13×10^{-10})] without exhibiting oscillation through an immiscible liquid column, the expressions suggested by Srinivasan and Satyanarayana¹ for drops in fall under gravity without exhibiting oscillation through an immiscible liquid column, hold good, viz.,

$$F = KD^2 u^2 \sigma (\eta / \sigma u D)^{1/2} (\rho / \sigma)^{1/2},$$

or (1)

$$F = KD^{3/2} u^{3/2} \eta^{1/2} \rho^{1/2}.$$

The method of arriving at these expressions has already been dealt with in detail¹. At the terminal velocity, for drops in rise against gravity without exhibiting oscillation through an immiscible liquid column, the buoyant force $(4\pi r^3 \sigma g / 3)$ of the liquid is equal to the sum of the weight of the drop, $(4\pi r^3 \rho g / 3)$ and the drag force F . That is,

$$4\pi r^3 \sigma g / 3 = (4\pi r^3 \rho g / 3) + F,$$

$$\therefore F = 4\pi r^3 (\sigma - \rho) g / 3. \quad (2)$$

Eq. (2) in eq. (1) gives

$$K = \sqrt{2} \pi g (r/u)^{3/2} (\sigma - \rho) / 3 \eta^{1/2} \rho^{1/2}, \quad (3)$$

$$u = (2\pi^2 g^2 r^3 (\sigma - \rho)^2 / 9 \eta K^2 \rho)^{1/3}, \quad (4)$$

$$\sqrt{2} \pi g S / 3 K = 1, \quad (5)$$

where

$$S = [(r/u)^{3/2} (\sigma - \rho)] / [\eta^{1/2} \rho^{1/2}], \quad (6)$$

and $g = 9.8 \text{ m s}^{-2}$, the acceleration due to gravity.

Eq. (6) (just as in the case of falling drop) is of vital importance in the sense that it may be used to determine the density ρ of the liquids which are lighter than the immiscible liquid column when conventional methods fail¹. Eq. (6) may be written as a quadratic equation from which

$$\rho = \{2\sigma + \lambda + [\lambda(\lambda + 4\sigma)]^{1/2}\} / 2, \quad (7)$$

where

$$\lambda = S^2 \eta / (r/u)^3. \quad (8)$$

S has been found to be approximately a constant for all systems studied here (see Table 3), the mean value of which is $0.3176 \text{ m}^{-1} \text{s}^2$.

Experimentally-observed data points predict a value for the constants S and K . The interval within which the predicted value of S and K holds good have to be ascertained for acceptability. Since an uncertainty analysis will help in establishing the uncertainty or error limits, which reveal the interval within which the predicted value of S and K holds good for acceptability, an attempt has been made here to adopt statistical method or technique²⁹⁻⁴⁰, which will enable to estimate and bring out the confidence limits (interval) within which the experimentally predicted value for S and K is an acceptable value of the parameters. Let $(x_1, \hat{y}_1), (x_2, \hat{y}_2), \dots (x_n, \hat{y}_n)$ be the n pairs of observations on the variables (observables) x and \hat{y} . Let the relationship between x and \hat{y} be of the form

$$\hat{Y} = \hat{A} + \hat{B}X. \quad (9)$$

Let the line of regression (best-fit)^{29,30} of \hat{Y} on X be

$$Y = A + BX. \quad (10)$$

Let the error estimate or residual^{29,30} as given by the line of best-fit (eq. (10)) be e , that is,

$$e = \hat{Y} - Y, \quad (11)$$

where Y is the estimated value as given by the line of best-fit (eq. (10)) for a given value of X . A (ref. 29) and B (ref. 29) are being estimated from

$$A = (\sum \hat{Y} - B \sum X) / n, \quad (12)$$

where

$$B = \{\sum X \hat{Y} - (\sum X \sum \hat{Y}) / n\} / \{\sum X^2 - (\sum X)^2 / n\}. \quad (13)$$

The expressions²⁹ giving $(1 - \alpha)$ per cent confidence limits for the regression parameters \hat{A} and \hat{B} are respectively,

$$\hat{A} = A \pm S_a t_{\alpha, n-2}, \quad (14)$$

$$\hat{B} = B \pm S_b t_{\alpha, n-2}, \quad (15)$$

where $t_{\alpha, n-2}$ is the table value for the two-tailed test at α level of significance and for $(n - 2)$ degrees of freedom. S_a and S_b are the standard error of A and B respectively, and they are expressed as²⁹

$$S_a = \{S_e^2 \{ (1/n) + [(\sum X/n)^2 / (\sum X^2 - ((\sum X)^2/n))] \}\}^{1/2}, \quad (16)$$

$$S_b = \{S_e^2 / \{\sum X^2 - ((\sum X)^2/n)\}\}^{1/2}. \quad (17)$$

S_e is the mean square error which is expressed as²⁹

$$S_e = \{ \{ [\sum \hat{Y}^2 - ((\sum \hat{Y})^2/n)] - B[\sum X \hat{Y} - ((\sum X \sum \hat{Y})/n)] \} / (n - 2) \}^{1/2}. \quad (18)$$

In the present study, eq. (6) may be written as

$$\rho^{1/2} / (\sigma - \rho) = 0 + (1/S) [(r/u)^{3/2} / \eta^{1/2}]. \quad (19)$$

This equation is of the form of eq. (9) and we get $\hat{Y} = \rho^{1/2} / (\sigma - \rho)$; and $X = (r/u)^{3/2} / \eta^{1/2}$. These in eqs 12, 13,

16, 17 and 18, give the estimated value of A , the estimated value of B $[=(1/S)_{\text{estimated}}]$, S_a , S_b and S_e respectively. Eqs (14) and (15) give $(1 - \alpha)$ percent confidence limits for regression parameters \hat{A} and \hat{B} respectively for $t_{\alpha, n-2}$ table value for the two tailed t -test at α level of significance of $(n - 2)$ degrees of freedom. It is obvious from eq. (15),

Highest confidence limit of

$$\hat{B} (= 1/S) = B + S_b t_{\alpha, n-2}, \quad (20)$$

Least confidence limit of

$$\hat{B} (= 1/S) = B - S_b t_{\alpha, n-2}, \quad (21)$$

Confidence interval

$$\hat{B} \text{ is } (B - S_b t_{\alpha, n-2}) \text{ to } (B + S_b t_{\alpha, n-2}), \quad (22)$$

Least confidence limit of

$$S = \{1/[B + S_b t_{\alpha, n-2}]\}, \quad (23)$$

Highest confidence limit of

$$S = \{1/[B - S_b t_{\alpha, n-2}]\}, \quad (24)$$

Confidence interval of S is

$$[1/(B + S_b t_{\alpha, n-2})] \text{ to } [1/(B - S_b t_{\alpha, n-2})]. \quad (25)$$

Since by eq. (5), $K = \sqrt{2\pi g S/3}$,

Least confidence limit of

$$K = (\sqrt{2\pi g/3})/[B + S_b t_{\alpha, n-2}], \quad (26)$$

Highest confidence limit of

$$K = (\sqrt{2\pi g/3})/[B - S_b t_{\alpha, n-2}], \quad (27)$$

Confidence interval of

$$K = (\sqrt{2\pi g/3})/[B + S_b t_{\alpha, n-2}] \text{ to } (\sqrt{2\pi g/3})/[B - S_b t_{\alpha, n-2}], \quad (28)$$

within these limits (interval) the experimentally predicted value for S and K is an acceptable value of the parameters S and K respectively.

A long graduated cylinder (diameter 5 cm) filled with the experimental liquid was used. Test liquid drops of known volume were gently injected at the bottom of the liquid column using a graduated Hamilton Precision micro-syringe. For injection, a small side tube attached to the graduated cylinder at the bottom and sealed with a septum was used. The rising drops and the liquids in the column were immiscible. Terminal velocity ' u ' was determined by observing the time ' t ' required by the liquid drop of radius ' r ' to cover the distance ' d ' between two graduations on the column. The drops studied here while rising are ellipsoidal in shape. If ' V ' is the volume of the drop of equivalent radius ' r ', then,

$$r = (3V/4\pi)^{1/3}.$$

The thirteen systems studied are given in Table 1. Density, viscosity and interfacial tension given in Table 1 were determined by the specific gravity bottle method, Ostwald viscometer and method of drops, respectively. As seen for drops in fall under gravity¹, here also, in the case of drops in rise against gravity, (r/u) is approximately constant (Table 2). Three data points each for seven liquid-drop pairs are alone given in Table 2. For the other liquid-drop pairs given in Table 1, the experimental results obtained show that the same (r/u) , approximately constant) holds good.

The value of S has been found to be approximately constant (Table 3) for all systems, just as observed for

*The constant of eq. (3); *S of eq. (6); **By eq. (10) $Y = A + BX$

By eq. (12) using data points given in Table 4, $A = -0.0003$

By eq. (13) using data points given in Table 4, $B = 3.1601$

***By eq. (11) $e = \hat{Y} - Y$

From Figure 1, $S = 0.3175 \text{ m}^{-1} \text{ s}^2$; $K = 4.6074$

Estimated value of $K = \sqrt{2\pi g/3B} = 4.5920$; $g = 9.8 \text{ m s}^{-2}$; (r/u) , ρ , σ , and η from Table 1.

Figure 1. Plot of data given in Table 3.

drops in fall under gravity¹. Experimental data points given in the fourth and fifth columns of Table 3 in eq. (6) give S of which $S_{\text{mean}} = 0.3176 \text{ m}^{-1} \text{ s}^2$ (Table 3). Comparison with drops in fall under gravity¹ (where the mean value of S is $0.2483 \text{ m}^{-1} \text{ s}^2$) clearly shows that the value of S remains positive for drops in rise against gravity as observed for drops in fall under gravity¹. The expression revealing the relation between S and K , here eq. (5), is the same as eq. (7) given by Srinivasan and Satyanarayana¹ and also for expressions ρ and λ .

Comparison of eqs (2)–(4), (6) and with those of expressions, F , K , u and S given by Srinivasan and Satyanarayana¹, shows that they are of similar form except for the fact that ρ and σ have just interchanged their positions.

S (eq. (6)) involves two terms $(r/u)^{3/2}/\eta^{1/2}$ and $\rho^{1/2}/(\rho - \sigma)$. The values of these terms are given in Table 3. A graph (Figure 1) is drawn with $(r/u)^{3/2}/\eta^{1/2}$ along the X-axis and $\rho^{1/2}/(\sigma - \rho)$ along the Y-axis. Referring to eq. (3), it may be seen that the slope of the line in the graph is $\sqrt{2\pi g/3K}$ which works out to be 3.1500. The slope value leads to $K = 4.6074$. This slope value, by eq. (5), i.e., $\sqrt{2\pi g S/3K} = 1$ gives $S = 0.3175 \text{ m}^{-1} \text{ s}^2$.

Experimental values of $(r/u)^{3/2}/\eta^{1/2}$ and $\rho^{1/2}/(\sigma - \rho)$ given in Table 3, in eq. (3), give the value of K of which $K_{\text{mean}} = 4.6090$ (Table 3). Eq. (5) may also be used to determine K and K_{mean} .

While attempting to predict values for S and K , it becomes necessary to carry out uncertainty analysis which will help in establishing with experimental data points, the uncertainty or error limits of S and K . Therefore, as a point of interest, error analysis has also been carried

out here, with experimental data points to estimate confidence limits (interval) of S and K , and to find out the error estimate 'e'.

With $n = 13$ and using the data given in Table 3, viz. $X = (r/u)^{3/2}/\eta^{1/2}$ and $\hat{Y} = \rho^{1/2}/(\sigma - \rho)$, or data points given in Table 4 in eqs (12), (13), (16), (17) and (18) give respectively

$$A = -0.0003,$$

$$B = 3.1601,$$

$$S_a = 0.0013,$$

$$S_b = 0.0220,$$

$$S_e = 0.0019.$$

$1/B$ gives the estimated value of S which is 0.3164. This value is nearly equal to the observed value of S given in the 6th column of Table 3 with negligible percentage of error. Likewise, $\sqrt{2\pi g/3B}$ gives the estimated value of K which is 4.5920. This value differs with negligible percentage of error with the observed values of K given in the 7th column of Table 3. The error estimate or residual 'e' is given in Table 3. From Table 3, it may be seen that 'e' is negligibly small.

Now, for $t_{\alpha, n-2}$, the table value of t for $n - 2 (= 11)$ degrees of freedom and α (5, 2, 1 and 0.1) per cent level of significance²⁹ $t_{\alpha, 11}$ are respectively 2.201, 2.718, 3.106 and 4.437 for the two-tailed t -test. For these values, with value $B = 3.1601$ and $S_b = 0.0220$, eqs 20–28 give the significant values related to the confidence limits (interval) of \hat{B} , S and K are as shown in Table 5.

RESEARCH COMMUNICATIONS

Table 3 gives mean observed value of $S = 0.3176 \text{ m}^{-1} \text{ s}^2$; $K = 4.6090$. Figure 1 gives $S = 0.3175 \text{ m}^{-1} \text{ s}^2$ and $K = 4.6074$. The error analysis giving significant values regarding confidence limits of S and K are given in Table 5. The values of S and K agree quite reasonably.

The estimated value, $0.3164 \text{ m}^{-1} \text{ s}^2$, the significant values of the enumerated confidence limits (interval) of the parameter S (Table 5) indicate that (i) $S = 0.3176 \text{ m}^{-1} \text{ s}^2$ (Table 3, the mean observed value experimentally predicted for the parameter S) is acceptable and (ii) by virtue of the importance of eq. (6), (the value of the parameter $S = 0.3176 \text{ m}^{-1} \text{ s}^2$) it is possible

to get fairly accurate density values by eqs (7) and (8) for liquids which are lighter than the immiscible liquids in the column and available in small quantities just as observed in the case of falling drops¹.

The values of K determined from the graph (Figure 1) and that determined from eq. (3) (Table 3) are 4.6074 and 4.6090 respectively and the mean of both (observed) is 4.6082. That is, 4.6082 is the value experimentally predicted for the parameter K . Looking at the estimated value, 4.5920, the significant values of the enumerated confidence limits (interval) of the parameter K (Table 5), it appears that (i) the value 4.6082, experi-

Using data points given in Table 4, by eq. (16), $S_a = -0.0013$ (= 0.001); By eq. (17), $S_b = 0.02220$ (0.022); by eq. (18), $S_c = 0.0019$ (= 0.002)

At $t_{0.05, 11}$, $\hat{B} = 3.1601 \pm 0.0484$, $S = 0.3165 \pm 0.0048$, $K = 4.5935 \pm 0.0697$
(3.16 \pm 0.048) (0.317 \pm 0.005) (4.59 \pm 0.070)

At $t_{0.02, 11}$, $\hat{B} = 3.1601 \pm 0.0598$, $S = 0.3166 \pm 0.0060$, $K = 4.5943 \pm 0.0864$
(3.16 \pm 0.060) (0.317 \pm 0.006) (4.59 \pm 0.086)

At $t_{0.01, 11}$, $\hat{B} = 3.1606 \pm 0.0688$, $S = 0.3165 \pm 0.0068$, $K = 4.5945 \pm 0.0999$
(3.16 \pm 0.069) (0.317 \pm 0.007) (4.60 \pm 0.100)

At $t_{0.001, 11}$, $\hat{B} = 3.1601 \pm 0.0976$, $S = 0.3168 \pm 0.0098$, $K = 4.5971 \pm 0.1420$
(3.16 \pm 0.098) (0.317 \pm 0.010) (4.60 \pm 0.142)

The mean observed value experimentally predicted (i) for $S = 0.3176$ (= 0.318) $\text{m}^{-1} \text{ s}^2$ (Table 3, Mean value 0.3176 $\text{m}^{-1} \text{ s}^2$; From Figure 1, 0.3175 $\text{m}^{-1} \text{ s}^2$); (ii) for $K = 4.6082$ (= 4.61) (Table 3, Mean value 4.6090; From Figure 1, 4.6074).

In the brackets, the values are given in three significant figures for easy perusal of the error limits.

mentally predicted for the parameter K is acceptable (ii) and hence, for the motion of a liquid drop in rise or rising upward against gravity through an immiscible liquid column without exhibiting oscillation of fairly high Reynolds number, Re (from 25 to 495), Eotvos number, E_t [from (2×10^{-2}) to (70×10^{-2})] and Morton number, Mo [from (2.06×10^{-12}) to (7.13×10^{-10})], the experimentally predicted value 4.6082 for the constant K in the drag force expression eq. (1) is acceptable.

If only three significant figures (given in brackets in Table 5) for the parameters S and K are considered, it may be seen that the error limits lie on either side of the value of $S = 0.317 \text{ m}^{-1} \text{ s}^2$ and for the value of $K = 4.59$ or 4.60, the mean of which is 4.60. The experimentally observed value for S and K when expressed up to three significant figures, become $0.318 \text{ m}^{-1} \text{ s}^2$ and 4.61 respectively. That is, they predict in two significant figures $0.32 \text{ m}^{-1} \text{ s}^2$ for S and 4.6 for K . In other words, in the drag force expression eq. (1), the value of K is 4.6.

The motion of the drop in rise against gravity may be thought to be just opposite to that of the motion of a drop in fall under gravity. The results for the drops considered in rise against gravity show that the proportionality constant K in the drag force expression (eq. (1)) is 4.6082 and the mean value of the constant S (eq. (6)) is $0.3176 \text{ m}^{-1} \text{ s}^2$. In the case of falling drop, for drops in fall under gravity¹, the value of K and S are respectively 3.6094 and $0.2483 \text{ m}^{-1} \text{ s}^2$. A comparison shows that values obtained for K and S for drops in rise against gravity differ from those values obtained for drop in fall under gravity¹ and furthermore, K and S remain positive for both viz., drop in rise against gravity and drop in fall under gravity¹.

Eq. (4) with $K = 4.6082$ may be used to predict the terminal velocity (just as seen for drop in fall under gravity¹) of the drop rising against gravity without exhibiting oscillation if r , η , σ and ρ are known. Using eqs (7) and (8) with the mean experimental value of $S = 0.3176 \text{ m}^{-1} \text{ s}^2$ (Table 3), if r , u , η and σ are known, one may determine (as seen for drop in fall under gravity¹) density ρ of the drops for which density cannot be determined by the capillary tube method where weighing is a problem or by any other conventional method¹.

Error analysis (confidence limits/interval) indicates that (i) getting fairly accurate value for density ρ with $S = 0.3176 \text{ m}^{-1} \text{ s}^2$ is possible and (ii) for the fresh drag force expression eq. (1), the experimentally predicted value 4.6082 for the constant K is acceptable.

If only two significant figures are considered, the observed value, the estimated value and the central value about which error limits lie, show that $S = 0.32 \text{ m}^{-1} \text{ s}^2$ and $K = 4.6$.

Inter-conversion of chemiosmotic parameters and its inhibition in *Thiobacillus ferrooxidans*

Niladri S. Kar, Tapas Kr. Datta and
Anjan Kr. Dasgupta

Department of Biochemistry and Biophysics, University of Kalyani,
Kalyani, Nadia 741 235, India.

In *Thiobacillus ferrooxidans*, an iron oxidizing obligatory acidophilic bacterium, bioenergetics was found to be critically dependent on sulphate distribution across its membrane. Under physiological condition, the sulphate distribution was found to be far from its electrochemical equilibrium, and a high residual proton motive force (~110 mV) remained conserved under varying external pH even in respiration-starved cells. The inter-conversion between bioenergetic parameters, namely membrane potential and pH gradient, was inhibited at a critical, low pH. Below this critical pH, proton-coupled sulphate influx was observed, as measured by radio-labelled transport assay, leading to collapse of the two chemiosmotic gradients. The associated alteration of membrane structure and permeability property was monitored by intrinsic fluorescence of *T. ferrooxidans* and extrinsic fluorescent probes.

ACIDOPHILIC bacteria have the remarkable ability to maintain their cytoplasmic pH close to neutrality even when external pH is below 4 (refs 1, 2). These cells, thus, can be taken as model system of chemiosmotic theory *in extremis*. According to this theory, the primary free energy available to a cell is its proton motive force (PMF)³, which is composed of two parameters, namely the chemical gradient and the electrical gradient of proton:

$$\Delta p = 60 \Delta \text{pH} - \Delta \psi, \quad (1)$$

where $\Delta \psi$ and ΔpH are membrane potential and pH gradient across the energy-transducing membrane, respectively. Obviously, chemiosmotic theory demands a mechanism of inter-conversion between these two parameters so that PMF can be kept constant. Moreover, since cytoplasmic pH is fairly conserved, the membrane potential varies under different physiological conditions. Most of the acidophiles, including *T. ferrooxidans*, are reported to have inside positive $\Delta \psi$; generation of membrane potential is observed in the presence of protonophores or in respiration-inhibited cells⁴⁻⁸. The respiratory chain of *T. ferrooxidans* utilizes oxidation of Fe^{2+} to Fe^{3+} , and therefore, the available free energy is so small that cytochrome oxidase cannot pump protons from the cytoplasm to the external medium^{9,10}. Thus, an efficient mechanism for respiration-independent ΔpH -

$\Delta \psi$ inter-conversion may be present in this organism, which is yet to be reported explicitly.

The initial objective of this work was to detect physiological limits of the interconvertibility of the two bioenergetic parameters. Our preliminary observation indicates that there exists a critical external pH, at which the inter-conversion fails¹¹. The mechanism of such failure may provide important insights towards better understanding of bioenergetic regulation in *T. ferrooxidans*.

T. ferrooxidans (ATCC 23270) was grown in 9 K medium¹² at pH 2.0 with aeration. Cells were harvested by centrifugation at 10,000 g for 15 min at 25°C, washed in ferrous free 9 K medium (9 K⁻) and 10 mM sulphuric acid (pH 2.0), filtered through a Whatman No. 1 paper and remaining trace of iron precipitate was removed by centrifugation on silicone oil (high density, $\rho = 1.050$) at 1,000 g for 3 min.

Membrane potential and internal pH were determined by using S^{14}CN^- and $[\text{C}^{14}]\text{acetate}$ by rapid centrifugation method^{4,13}. For measurement of membrane potential, cells at protein concentration of about 5 mg/ml were incubated with $^3\text{H}_2\text{O}$ (5 $\mu\text{Ci/ml}$) and KS^{14}CN (0.2 $\mu\text{Ci/ml}$). For pH gradient, $\text{Na}-[\text{C}^{14}]\text{acetate}$ (0.2 $\mu\text{Ci/ml}$) or $[\text{C}^{14}]\text{chloroacetate}$ (0.2 $\mu\text{Ci/ml}$) were used. After dual incubation with $^3\text{H}_2\text{O}$ and the probe for membrane potential or pH gradient for 5 min at room temperature, the cells were separated by rapid centrifugation through dibutyl phthalate ($\rho = 1.043$) at 12,000 g for 5 min. The bacterial pellet was dissolved in 1% SDS, diluted in scintillation cocktail-W and counts were taken in a liquid scintillation counter (Model LS 5000 TD, Beckman). The membrane potential and pH gradient were calculated using the following equations:

$$\Delta \psi = 60 \log \{ [\text{SCN}]_{\text{in}} / [\text{SCN}]_{\text{out}} \}, \quad (2)$$

$$\Delta \text{pH} = \log \{ [\text{A}]_{\text{in}} / [\text{A}]_{\text{out}} (1 + 10^{\text{pH}_{\text{out}} - \text{pK}_a}) - 1 \} + \text{pK}_a - \text{pH}_{\text{out}}, \quad (3)$$

where the subscripts 'in' and 'out' represent concentrations in the cytoplasm and the supernatant, respectively.

To measure internal buffering capacity of the whole cells and proton flux across their membrane, a procedure described previously⁸ was followed. Cells permeabilized with 10% Triton X-100 were suspended in water at concentration 3.5 mg/ml. After each addition of acid pulse of 2.5–10 μl 20 m(N) HCl, pH was measured by an expandable ion analyser (Model EA920, Orion Research Inc., USA). 10% Triton X-100 and intact cells suspended in water were used as two controls. The value of the buffering capacity was expressed in nmole of proton required to change the pH by one unit per mg of cell protein. To measure proton flux across membrane, cells at 3.5 mg/ml were suspended in unbuffered assay medium (dilute H_2SO_4) and treated as required. pH was

monitored at intervals and proton influx was calculated from alkalization of the external medium⁸.

Cells were suspended in 10 mM Tris-Cl (pH 7.0) containing 0.4 M sucrose and 20 mM EDTA and then treated with lysozyme at 0.2 mg/ml for 30 min. The reaction mixture was diluted with 0.4 M sucrose containing 10 mM MgCl₂. Swelling of the pre-formed spheroplasts was monitored by absorbance at 600 nm or by using ³H₂O.

The fluorescence experiments were carried out in a Shimadzu RF-540 spectrofluorometer at room temperature. Whole cells at 50 µg/ml were excited at 295 nm (2.5 nm slit) and the fluorescence spectra were recorded in the wavelength range 300–380 nm (2.5 nm slit). Quenching experiments were performed with excitation at 295 nm (slit 2 nm) and emission at 335 nm (slit 2–5) with increasing concentrations of quenchers: acrylamide 33.3–200 mM, copper sulphate 5–30 mM and potassium iodide 5–30 mM. Stern–Volmer constants were calculated from the slopes of F_0/F_1 vs $[Q]$ plots, where F_0 and F_1 were the unquenched and the quenched fluorescence intensities, respectively, and $[Q]$ was the quencher concentration¹⁴.

The cells at 100 µg/ml were incubated with 10 µM of 8-anilino-1-naphthalene sulphonate (ANS) for 15 min and the fluorescence spectra were obtained with maximum intensity of excitation at 365 nm (2.5 nm slit) and emission wavelength range 400–550 nm (2.5 nm slit).

The cells without or with protonophore were incubated with [³⁵S]sulphuric acid. Then they were isolated by oil centrifugation and isotope distribution in the pellet and the supernatant was measured at different time intervals. To calculate internal concentration of sulphate, the internal volume was determined by ³H₂O distribution.

The earlier reports on bioenergetics of *Thiobacilli* have claimed that maintenance of internal pH in the acidophiles is not an energy-dependent process^{4,8}. In respiration-inhibited *T. ferrooxidans* and *T. acidophilus*, PMF of about 58 mV and 36 mV have been reported, while in the active cells the pmf values were 256 mV and 90 mV, respectively^{4,5}. In both the cases cytoplasmic acidification was only by 0.4 pH unit. We report here existence of a protonophore-sensitive PMF and its conservation over a pH range in the non-respiring *T. ferrooxidans* cells. When *T. ferrooxidans* cells were incubated in 9K⁺ medium of pH 1.8 to pH 3.4, membrane potential and pH gradient were found to decrease with increasing external pH (Figure 1), with pmf remaining conserved at about 110 mV. When the external medium was replaced by β -alanine sulphate buffer of respective pH, the values of these parameters remained virtually the same. Over the pH range under study, therefore, the $\Delta\psi$ – Δ pH inter-conversion is neither a respiration-dependent process nor dependent on alkali-uptake by the cells.

Figure 1. pH profiles of relative ferrous oxidation activity and bioenergetic parameters of *T. ferrooxidans*. Oxidation activity (Δ), membrane potential (O) and pH gradient (□) were measured in non-respiring condition as described in text. The cells were starved for about 6 h during their harvesting and purification.

As pointed out by several workers, the redox span (ΔE_h) between $\text{Fe}^{2+}/\text{Fe}^{3+}$ ($E_{m,2} = 780$ mV) and $\text{H}^+/\text{H}_2\text{O}$ ($E_{m,6.5} = 850$ mV) couples is only 70 mV and so in the respiring cells (where the membrane potential is small and PMF is high⁴), the electron transfer provides little scope for proton pump activity. However, this report indicates that the bioenergetics of the non-respiring cells might be qualitatively different. The large membrane potential that builds up in non-respiring cells is to be added to the redox span¹⁵, giving a Gibbs free energy change per electron translocation:

$$\Delta G = -F(\Delta E_h + \Delta\psi), \quad (4)$$

where F is the Faraday constant. Thus, respiration at pH 2.0 is expected to yield 22.7 kJ mol^{-1} in these cells compared to only 6.8 kJ mol^{-1} in the respiring cells. Though the implication of this is not yet clear, the generation of inside-positive membrane potential upon respiration deprivation appears to be thermodynamically beneficial, though perhaps transiently.

At very low pH (below pH 1.8), however, $\Delta\psi$ decreased discontinuously to a baseline at 65–70 mV. pH shift experiments indicated that after a brief exposure to such low pH, cells failed to regain high $\Delta\psi$ or to oxidize ferrous even when shifted to pH 2.0.

T. ferrooxidans showed typical pH dependence in its iron-oxidizing activity with a maximum near pH 2.0, its physiological pH (Figure 1). A comparison of the pH profile of iron oxidation and that of $\Delta\psi$ reveals remarkable similarity.

At pH 3.4 after treatment with 200 µM of 2,4-dinitrophenol (DNP), $\Delta\psi$ increased from 93 mV to 142 mV. These DNP-treated cells could respire as evident from ferrous oxidation after they were re-suspended at

pH 2.0. The value of cytoplasmic buffering capacity was found to be 95 nmole of proton per pH unit per mg of protein, while DNP-mediated proton influx was 65 nmole per mg of cell protein. Therefore, the cytoplasm should have been acidified by about 0.7 pH unit, which was exactly what was found by radio-isotopic measurement of pH gradient. Thus, though protonophore treatment gave rise to almost complete abolition of pmf, an appreciable Δ pH remained. The protonophore appears to introduce a proton influx that attains electrochemical equilibrium and becomes self-limiting in the absence of compensatory charge translocation^{2,8}. Under this condition, internal buffering capacity could provide protection against internal acidification. This passive mechanism of pH homeostasis is therefore important even in the non-respiring cells where increasing amount of proton remains unabated in the cytoplasm due to non-functioning terminal oxidase. Since the proton influx was comparable with the amount of DNP in the assay medium (57 nmole/mg of cell protein), prevention of reverse flow of the 'uncoupler' by inside-positive membrane potential suggested earlier¹⁶ seems to be operative.

Effect of protonophore treatment was, however, found to be external-pH dependent. At pH 1.8, for example, treatment with 200 μ M of DNP resulted in abolition of pH gradient. The cells were unable to respire after DNP was washed away. Interestingly, the change in the other chemiosmotic parameter was anomalous – $\Delta\psi$ was found to decrease from 199 mV to 68 mV. Collapse of $\Delta\psi$ in presence of protonophore has been reported in at least another acidophile and interpreted as non-specific disruption of membrane at high DNP concentration⁷.

Protonophore-induced collapse of the membrane potential, appreciable proton influx and inactivation of cells near pH 2 could only be accounted for by considering translocation of charges other than proton. Presumably, anion of assay medium could provide a compensatory conductance to proton influx under this condition.

Upon excitation at 275 nm or 295 nm, *T. ferrooxidans* cells showed an intrinsic fluorescence spectra with emission maximum at about 338 nm, presumably blue-shifted spectra of tryptophan (Trp) residues¹⁴. Comparison of relative intensity of intrinsic fluorescence of the membrane, its high-ionic strength removable and non-removable fractions, and cytoplasmic fraction showed the whole cell fluorescence was predominantly due to integral membrane protein¹¹. When external pH was varied from 1.1 to 3.5, the fluorescence intensity was found to increase with increasing pH with no appreciable shift in wavelength maximum (Figure 2a). Invariant emission maximum over the pH range indicates that the Trp residues were in a similar environment. Ionic collision quenchers of membrane-bound fluorophores have been used to monitor their accessibility to the fluoro-

Figure 2. Emission spectra of intrinsic fluorescence (a) and ANS fluorescence (b). External pH values were pH 1.1 (1), pH 1.5 (2), pH 1.9 (3), pH 2.9 (4) and pH 3.5 (5). Each intrinsic fluorescence spectrum was corrected for background fluorescence of buffer, and each ANS spectrum (ANS concentration 10 μ M) was corrected for buffer, free ANS and cells.

phore site^{14,17}. Stern–Volmer plots for various quenchers of Trp were found to be linear, suggesting one class of fluorophores (Figure 3). Over the pH range of 1.1 to 3.5, the Stern–Volmer constants (K_{SV}) for acrylamide and Cu^{++} were $3.04 \pm 0.18 \text{ M}^{-1}$ and $9.17 \pm 1.27 \text{ M}^{-1}$, respectively (Figure 3a and b). For I^- , however, K_{SV} increased with decreasing pH, dramatically near pH 1.6 (Figure 3c). Though K_{SV} of acrylamide and copper varied in narrow ranges, increase in the iodide-quenching constant at low pH suggests that the intrinsic fluorophores in the whole cells became more accessible to added anions.

Binding studies of ANS have been used to determine fixed charges on the membrane surface¹⁸. The pH profile of ANS fluorescence intensity showed discontinuity between pH 1.5 and 1.9 (Figure 2b). Below pH 1.4, slight red-shift in the emission spectra was also observed. The cells pre-incubated in such a low pH and then shifted to higher pH (i.e. pH 2.0) showed ANS spectrum similar to those suspended at the former pH. Thus, ANS fluorescence appears to monitor some irreversible alteration in the membrane structure at low pH.

Preliminary permeability study with spheroplasts showed osmotic swelling at higher concentrations of sulphate (Table 1), suggesting influx of sulphate and its counter-ion. The direct assay revealed a fast followed

Figure 3. Stern-Volmer plots for quenching of intrinsic fluorescence with acrylamide (a), copper (b) and iodide (c). pH 1.4: (O); pH 1.6 (□); pH 1.9: (●); pH 3.3: (■). Linear correlation coefficients were greater than 0.995.

by a slow sulphate distribution in the cells (Figure 4). At pH 2.0, the sulphate concentration in DNP-treated cells was about twice as much as that in the control. This is in conformation with our observation regarding anomalous changes in the bioenergetic parameters and compensatory anionic charge movement. Assuming the

Figure 4. Time kinetics of sulphate accumulation. Cells suspended in $9K^+$ medium (pH 2.0) at protein concentration of 5 mg/ml were incubated without or with 200 μ M DNP for 15 min and [^{35}S]sulphuric acid at final concentration of 0.05 μ Ci/ml was added to each tube at $t=0$ min. Pellet counts of aliquots were taken at intervals. Control (O), DNP treated (□).

Figure 5. pH profile of the electrochemical potential of sulphate ion across the membrane. The parameter was measured from sulphate distribution ratio and membrane potential: $\Delta\mu_{SO_4} = 2\Delta\psi - 60 \log ([SO_4]_{in}/[SO_4]_{out})$.

Table 1. Effect of sulphate on spheroplast swelling. For optical experiments, spheroplast preparation was suspended at protein concentration of 50 μ g/ml and incubated for 5 min with increasing sulphate concentration. For direct measurement of volume, the spheroplasts were suspended at protein concentration of 7 mg/ml in various sulphate concentrations for 5 min and the volume was obtained with 3H_2O

Sulphuric acid concentration (mM)	Absorbance at 600 nm	Volume (μ l/mg of protein)

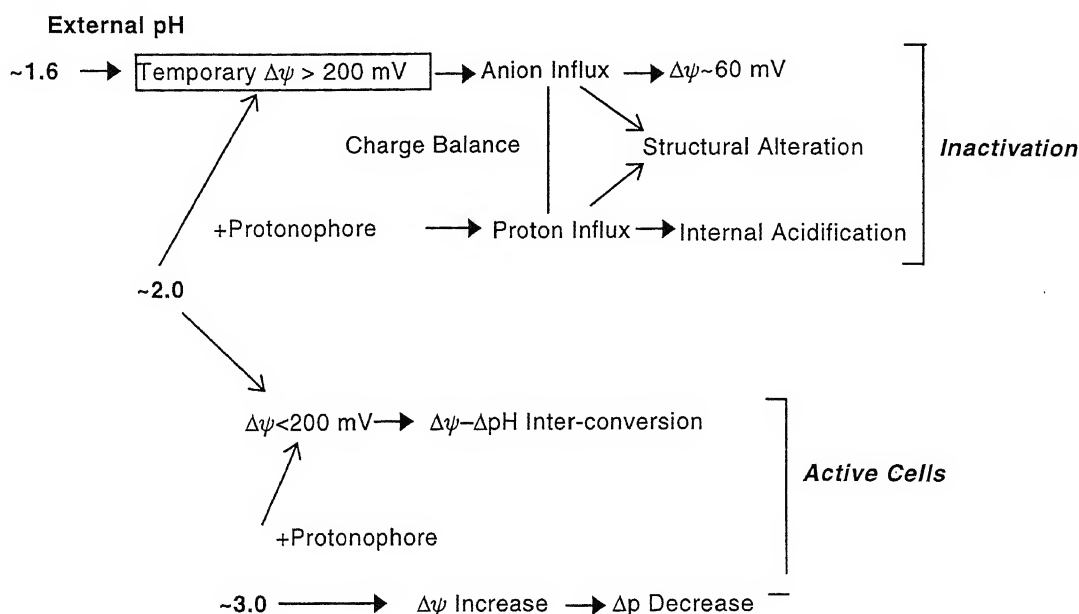

Figure 6. Scheme for relationship between bioenergetic parameters and ion uptake in *T. ferrooxidans*. Existence of a critical, high membrane potential has been proposed, above which the membrane breakdown phenomenon was observed.

at membrane potential of 165 and 52 mV, respectively. Thus, the sulphate ions are subjected to a high $\Delta\psi$ driven inward drag in the active cells, but not in the inactive cells.

The pH dependence of the electrochemical potential of sulphate ion is depicted in Figure 5. The critical pH induced increased sulphate permeability and consequently the sulphate electrochemical potential decreased toward the equilibrium. Inside-positive membrane potential in acidophiles may play some defensive role against cytoplasmic acidification and cation toxicity, but at the same time it may assist anion influx. In fact toxicity toward inorganic, monovalent anions in *T. ferrooxidans* has been shown to be due to their membrane-potential driven accumulation in the cytoplasm¹⁹. In *T. thiooxidans* protonated form of sulphite, sulphurous acid or sulphur dioxide has been reported to penetrate and acidify the cells²⁰. However, sulphate ion, having an appreciable dipole moment even in its fully protonated form, is likely to be impermeable to lipid bilayer. This is in agreement with our observation that sulphate was effectively excluded from the active cells. In fact, the electrochemical gradient of sulphate was sufficient to maintain a PMF of 110 mV over the pH range 1.8–4.0 (Figure 5). It is tempting to assume that an electrogenic sulphate transport system, perhaps directly coupled to proton translocation, plays some crucial role in bioenergetics of *T. ferrooxidans*.

So far, only limited interpretation is available to explain the characteristic pH profile of iron oxidation by

T. ferrooxidans. In this report, we propose a bioenergetic basis of its discontinuous decrease below the physiological pH. The cells appear to show increased anion permeability, leading to irreversible damage only under those situations where membrane potentials are expected to be very high. The cells were never found to possess a membrane potential value higher than 200 mV in equilibrium condition, which presumably represents a threshold. A plausible scheme is put forward to depict interplay between the chemiosmotic parameters and ion permeability in *T. ferrooxidans* (Figure 6). A transmembrane potential of 200 mV corresponds to an electrical field strength of about 300,000 V/cm. Such a high field may lead to dielectric breakdown – similar to non-ohmic leak/slip in state 4 mitochondrial respiration¹⁵. An increased fixed charge on the membrane surface, on the other hand, is also expected to affect membrane organization which in turn may lead to increased permeability. Our preliminary measurements of surface potential by spectroscopic probes suggest that near the physiological pH the surface potential is positive and increasing with decreasing pH¹⁸. Evaluation of the components of the membrane potential, viz. transmembrane potential and surface potential and their possible relation to the sulphate distribution, thus may lead to further elucidation of the bioenergetics and ion transport mechanisms in this organism.

Biodiversity visualization is a process by which diverse data sources varying from cover types, habitats to species inventories are integrated into a single computer environment. The integration affords a far better degree of spatial reasoning and understanding of biodiversity issues than hitherto attended to. We attempt here to integrate satellite data, digital elevation models derived from the toposheets, slope, aspect, elevation data and known information on some elements of biodiversity. The visualization tools were applied for a case study in Mehao Wildlife Sanctuary, north-east India, a global hotspot of biodiversity. The thematic features included in the visualization are habitats classified using the Landsat thematic mapper (TM) data, plant succession, hotspots of plant diversity, pheasant and takin habitat. The results were 'field tested' for acceptance among the user community. It is concluded that the visualization has a substantial role in furthering biodiversity conservation.

SCIENTIFIC visualization is defined as 'the study, development and use of graphic representation and supporting

techniques that facilitate visual communication of knowledge¹. The major objective of scientific visualization techniques is to process digital images to produce a simulated model leading to enhanced information content in the images². Biodiversity visualization is a means to achieve cognizance of spatial observations of biological diversity at many scales. This is usually achieved using computer-based scientific data visualization tools². Data visualization tools range from simple statistical bar charts to totally-animated realistic visual simulation and are intended to assist in the data-to-environment translation process. While this process of translating different states of environment into data and statistics exist, the converse of translating data to environmental images is less developed and often neglected³. The term biodiversity visualization denotes integration of diverse data sources on biological diversity – ranging from cover types, habitats, species inventories, birds and mammal vocalizations and so on into a single computer environment³. In the context of biodiversity research, the chief goal for data visualization lies in achieving accurate and verifiable representation of existing and projected environmental scenarios². The rationale for pursuing visualization is that it aids the scientist with better tools to grapple with the complex issues on patterns of distributions of species, ecosystems and landscape. The manager and policy makers likewise can readily comprehend the issues for day-to-day management. In this paper, we present a case study of data visualization in biodiversity research in north-eastern India, a globally recognized hotspot of biodiversity. The goal is to demonstrate use and integration of digital satellite data, digital elevation models, spatial terrain analyses such as slope, aspect and known information/data on vegetation, mammals and birds. We dem-

onstrate in particular the use of GIS overlay analyses to derive vegetation vulnerable to change, hotspots of plant diversity, pheasant habitats and habitats of rare and endangered mammal, takin.

The study area (28° to 28°15'N Lat., 95°45' to 95°50'E Long.) comprises 281.5 km² of lesser Himalayas of north-east India in the Dibang Valley district of Arunachal Pradesh. This area has been declared as wildlife sanctuary and is being managed for conservation of the unique values of biological diversity. Amongst the most notable features of this sanctuary is an altitudinal gradient spanning from a few hundred (500) to a few thousand (3300) metres of elevation, resulting in a variety of habitats, ecosystems and species. The habitats include tropical broad-leaved evergreen forests harbouring India's only ape, the Hoolock Gibbon and conifers in the higher altitudes, housing the endangered Red Panda. Blyths Trogon has recently been discovered in the sanctuary. Medicinal plants such as *Taxus baccata* and *Coptis teeta* occur and are extensively used by locals.

There are no published accounts on historical land use of this sanctuary. From the anthropological descriptions of various tribes and their customs⁴⁻⁶, it appears that there are no elaborate land laws nor any regulation of land use. The recent commercialization of timber from the forest gave a great impetus for both legal and illegal removal of timber from all accessible regions of the sanctuary. This is especially so in the lower (>1000 m) and mid (1000–2000 m) altitudes. The consequence of this exploitation has resulted in large-scale changes in vegetation. For example, it was observed that there is an increase in secondary vegetation and large-scale growth of bamboo. There seem to be discernible patterns of vegetation succession. For example, the cool northern aspects (the direction of slope, e.g. north, south, west, etc.) in the lower and mid-altitudes harbour *Musa* sp. and the southern aspects are often covered by bamboo and other deciduous vegetation. In the higher altitudes, the temperate evergreens dominate. Wherever disturbance is extensive, high altitude bamboo (*Schizostachyum* sp.) occurs widely. The alpine areas are located in altitudes exceeding 3200 m. The tree line is much closer (3000) to the alpine localities, compared to that of Western Himalayas.

Landsat TM digital data in bands 2, 3, 4 and 5 for 23 December 1993 were acquired for the study. The Survey of India (SOI) toposheets 91D04 and 82P16 covered the area of interest. Extensive field work in 1995 and 1996 provided the data for 'ground truth' and validation of remote sensing analyses and GIS modelling. The field work consisted of a) sampling tree, shrub and herb species composition at various altitudinal zones in 0.1 ha plots; b) sampling avian diversity in the same plots; c) obtaining ancillary information from the tribals on the distribution and abundance of pheasants and takin and; d) validation of the results.

For the entire study area, contours from SOI toposheets at 200 m interval were digitized in EASI/PACE environment on IBM RS6000 workstation at the Regional Remote Sensing Service Centre, Dehra Dun.

Digital Elevation Model (DEM) was created by the Morphology Dependent Interpolation Procedure (MDIP)⁷ in GRID interpolate (GRID INT) utility of EASI/PACE. Within GRID INT the CONIC option used as diagonal methods was found to be less satisfactory. The utility, PSGIMG (Image perspective) in Terrain Analysis module was used to obtain the terrain model from the DEM.

A rectification procedure for earth rotation effect in the satellite data for bands 2, 3, 4 and 5 was done using various utilities in the module of geometric correction. Necessary Ground Control Points (GCP) were taken from the SOI toposheets. An accuracy of 2 pixels only could be obtained as there have been substantial changes in river, road junctions and even the courses of river/streams. There are very few roads to specify precise GCPs. In terms of physical limits, the accuracy represents a ground area of 0.18 ha since each TM pixel is of 30 × 30 m size.

A False Colour Composite (FCC) was generated using bands 5, 4 and 3. The sanctuary boundary was digitized on to the rectified data and all further analyses were confined to this locality only.

The DEM was used in obtaining aspect (ASP) and slope (SLP) images of the sanctuary. Two utilities, ASP and SLP in the module of terrain analysis were used to obtain the above images. The two, along with elevation images, represent important habitat variables for biodiversity research.

The multi-layer modelling routine in EASI/PACE, permits a user-defined modelling approach. This involves specifying the precise nature of model and the computational procedure. GIS raster modelling was done to 1) locate hotspots of plant diversity; 2) vulnerable areas of vegetation change; 3) pheasant habitat suitability and 41 potential takin habitats.

The resulting images from the GIS raster modelling were draped onto the DTM in FLY! programme of EASI/PACE. The entire area was traversed at varying view angles, altitudes, magnification and at different locations. The resulting visualization afforded 1) better method of locating 'ground truth' samples for classification and 2) verifying the accuracy of various classification schemes adopted.

The false colour composite draped onto DTM is given in Figure 1. An unsupervised classification was done by *k*-means classifier. The classifier is essentially a clustering algorithm computing sample means through an iterative procedure⁷. The recruiting theme map provides each cluster with a specific grey value. A total of 36 spectral classes were obtained. With the help of ground

Figure 1. An FCC of TM bands 5, 4, 3 of Mehao Sanctuary, draped on Digital Terrain Model (DTM). The two rivers in the foreground are tributaries of Deopani river. The snow-capped mountains are at the rear. A two-dimensional FCC of the locality is in the inset.

Figure 2. An unsupervised classification of TM bands 2, 3, 4, 5 gave broadly identifiable patterns of biomes. The various hues depict different spectral classes corresponding to habitat categories. In the foreground of the picture lies Mehao lake, a major landmark.

Figure 3. A supervised classification of TM bands 2, 3, 4, 5 resulted in the identification of eight major habitat categories including shades caused by high relief (shown in grey). The snow-capped mountain ridge is seen in the background.

Figure 4. The thematic layers of habitat categories were analysed along with slope, aspect and elevation layers to identify vulnerable areas of vegetation changes.

Figure 5. The results of field sampling on plant diversity were overlaid on physical attributes such as slope, aspect and elevation to obtain 'hotspots' of plant diversity. The yellow patches in the picture show these localities.

truth samples, these classes were later coalesced into 12 categories. The results were draped on DTM and are shown in Figure 2. There is abundant heterogeneity in the classes obtained. However, the high altitude habitats can be demarcated easily from the lower altitude habitats.

A supervised classification was done using maximum likelihood classifier. The accuracy of the classification was found to be only 80%. Again, a substantial extent of heterogeneity appears to contribute to the somewhat low accuracy. A thorough field check confirms the heterogeneity in small spatial unity. The results of supervised classification draped on DTM are shown in Figure 3.

The GIS models used were of necessity simple in nature. This is due to the fact that there are no ecological

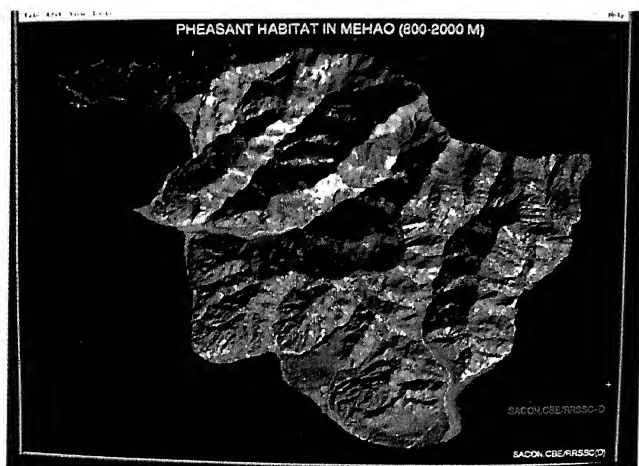

Figure 6. Pheasant habitats in the altitudinal range of 800–2000 m were identified and are shown in green colour.

and natural history studies in this area which could shed light on plausible models to be used. Since physical variables such as elevation, slope and aspect are important determinants of distribution of vegetation/habitat categories, these variables were used in four thematic features of relevance to biodiversity. It is to be pointed out that this is obviously an illustrative attempt and not comprehensive.

It is known that vegetation is vulnerable to change due to human activity. This is especially so in the south-facing accessible slopes ($<30^\circ$) with deciduous vegetation. Southern aspects by virtue of their longer duration of exposure to harbour, dry habitats with serial stages prone to change. In the overlay these conditions, e.g. deciduous vegetation on southern and south western aspects with slopes of less than 30° with altitude of less than 1800 m were specified. The percentage pixels qualifying these criteria was found to be only 2.83. The total area is 795 ha. However, spatially speaking, these locations are spread over the entire area. The results were draped onto the DTM (Figure 4).

From the field sampling on plant diversity, it appears that northern aspects with evergreen vegetation are likely candidate sites for hotspots. The hotspots are those that have highest species richness in the field samples. These were located by specifying masks for slope, aspect, elevation and vegetation themes. The mask size is 281.5 km². The percentage of pixels qualifying these conditions is 0.84. Hence, the total area under hotspots is 236 ha. A part of the hotspots draped on DTM is given in Figure 5.

This area is known for its pheasants. Blyth's tragopan, a highly endangered pheasant is routinely hunted. From the available information on habitat preferences of pheasants between 800 and 2000 m altitude, using the thematic covers of vegetation, slope, aspect, an overlay analysis indicated 1.4% of the geographical area

Figure 7. The preferred high altitudes of pheasants were identified using overlay analysis and the results were draped in DTM. The localities in green colour indicate these habitats.

Figure 8. Takin, an endangered mammal, occurs in sparse numbers. The likely locality of occurrence are shown in yellow colour.

as suitable habitat. This works out to be 393 ha. The area is shown in Figure 6.

At higher altitudes (>2000 m), the winter habitat of pheasants is largely restricted to south-facing slopes. An overlay analysis using southern aspects with evergreen, semi-evergreen vegetation cover themes indicated 0.57% area as suitable habitat. This works out to be 150 ha spread over the entire area (Figure 7).

Takin, the largest representative of Rupicaprinae of the Bovidae inhabits some of the steepest mountains in mid-altitude tropical evergreen forests (90° –1200 m). It has a narrow range of global distribution, being confined to a few patches in Bhutan, part of China and parts of Arunachal Pradesh⁸.

Takin, is therefore a flagship species of biodiversity in Mehao and is an extremely rare mammal to be encountered. However, the hunters appear to hunt these animals

(which only points to the extent and depth of their knowledge on environment). From detailed description of the preferred habitat, using overlay analysis of slope, aspect, elevation and vegetation classes, we obtained the preferred habitats of Takin (Figure 8). The preferred habitat constitutes just 0.11% of the sanctuary. In real terms the extent is a mere 30 ha. This is possibly the major reason for the observed low encounter rates. It also points to the need of including available habitat outside of Mehao in a bigger viable conservation unit.

Visualization in biodiversity research entails a whole spectrum of potential benefits at the levels of species, ecosystem and at landscape. An explicit spatial dimension – in terms of patterns of distribution of the above three components of biodiversity, can be provided. This is especially useful in underexplored and relatively unknown field locations using simulated environmental images. The Rapid Biodiversity Assessment (RBA) procedures stand to gain immensely by using visualizing tools. As a sequel to RBA one could effectively use the visualization for evolving comprehensive and appropriate sampling designs for biodiversity description, assessment and monitoring.

For the routine natural history surveys of endangered rare species, one can use available information, howsoever meagre, along with visualization tools to focus the surveys in well-defined geographical locations. Such focused surveys of course, are not only cost effective but could contribute to better formulation of habitat suitability models for a number of species.

We thought it would be better to elicit reaction to these visualizations and perceived impressions on utility for field personnel. We have shown these and the two-dimensional photos to a wide group of people in the sanctuary. It was amazing to find the ease with which the people identified ground features draped on DTM. These persons could identify vegetational and terrain features much more easily and preferred the three-dimensional pictures.

The results on visualization can be altered/improved based on availability of further field data or models of habitat utilization of species of interest. Again, in the area of EIA studies, these visualization tools hold great promise in communicating the data in the form of environmental images to a wide group of users.

In conclusion, we hold the opinion that this methodology and its applications will find wider use in the coming years. This will undoubtedly go a long way in baseline information collection, assessing and monitoring biodiversity in ever-changing environment.

Transient expression of β -glucuronidase reporter gene in embryogenic callus cultures of an elite indica basmati rice (*Oryza sativa* L.)

D. Minhas*, S. Bajaj[§], A. Grover* and M. V. Rajam^{§†}

Departments of Genetics[§] and Plant Molecular Biology*, University of Delhi, South Campus, Benito Juarez Road, New Delhi 110 021, India

Various parameters for the introduction of β -glucuronidase (GUS) reporter gene driven by actin-1 promoter into embryogenic callus cultures of an elite indica basmati rice cultivar (Basmati 370) through biolistic delivery method were studied. Helium gas pressure of 900 psi, arrangement of the callus at the centre of the plate or 1100 psi helium pressure and arrangement of the callus at the innermost concentric ring of the plate along with 6 cm distance from the microcarrier produced best results in terms of transient GUS expression, but with moderate callus survival. However, better survival of the callus with moderate GUS expression was observed when the callus was placed at the centre or the innermost concentric ring of plate with a distance of 9 and 6 cm using 900 and 1100 psi, respectively; and these parameters may be useful in recovering transgenics. These parameters will now be employed for the development of fertile transgenic basmati rice harbouring agronomically useful genes.

SIGNIFICANT progress has been made in the last two decades in the improvement of important cereals, such as rice, through conventional breeding methods.

RESEARCH COMMUNICATIONS

However, application of genetic manipulation techniques is becoming increasingly important for rice improvement to cope with its growing need. Although, genetic transformation through *Agrobacterium* is very effective and a widely used method of obtaining transgenic plants in dicots, it is still a difficult proposition in monocots, including rice, though some success has been achieved in this respect, of late^{1,2}. Therefore, other methods of gene transfer such as particle gun, electroporation of polyethylene glycol-mediated transformation have been used for the achievement of fertile transgenic rice³⁻⁵ and other cereals^{6,7}. However, all of these reports have come from laboratories abroad. Certain elite indica rice cultivars, which are widely grown in our country, have not been used for these studies. Regeneration protocol from callus cultures in Basmati 370 which is an aromatic, fine-grained and highly-priced rice cultivar has been standardized in our laboratory⁸ with the aim of establishing transformation protocol in basmati rice. In this communication, we report, for the first time, the transient expression of β -glucuronidase (GUS) reporter gene through biolistic delivery in mature embryo-derived embryogenic callus cultures of rice (*Oryza sativa* L. cv. Basmati 370).

Mature seeds of rice were de-husked, surface-sterilized with 0.1% HgCl₂ for 20 min and then rinsed with several changes of sterile distilled water. For callus induction, the seeds were placed on Murashige and Skoog (MS)⁹ medium supplemented with 2 mg/l 2,4-dichlorophenoxyacetic acid (2,4-D) and cultured in dark at 26 \pm 1°C. Following three weeks of culture, the callus induced contained both embryogenic as well as non-embryogenic regions. Embryogenic regions were excised and cultured on the same callus medium for another 2 weeks as described earlier¹⁰.

The PDS-1000 He biolistic particle delivery system (Bio-rad, USA) was employed in the present experiments and the microprojectiles were driven by helium pressure. The gene construct used was actin-1 promoter-actin 1 intron-gus-tnos (obtained from D. McElroy, CSIRO, Australia). Other details of this plasmid construct are published elsewhere¹¹.

The microcarriers (DNA-coated gold particles) were prepared by sterilizing 60 mg gold particles (Bio-rad, USA) with 1 ml of absolute ethanol in an eppendorf tube and kept at room temperature for 20 min. Following incubation, the particles were spun down and washed thrice with sterile distilled water and resuspended in 1 ml 50% glycerol. For DNA/particle precipitation, 12 μ g of plasmid DNA (DNA concentration 1 mg/ml) was added to 50 μ l of these particles, along with 50 μ l of 2.5 M CaCl₂ and 20 μ l of 5 M spermidine. Following vortexing and 20 min of precipitation at room temperature, the particles were spun down and resuspended in 140 μ l 70% ethanol. This procedure was repeated once with 40 μ l ethanol. Finally, 6 μ l of the suspension was used per shot.

Table 1. Bombardment conditions employed in the present investigation on basmati indica rice callus

Distance between rupture disc and macrocarrier	0.5 inch + 15 mm
Size of gold particles	1 μ m
Distance between microcarrier and target	6 and 9 cm
Density of particles/shot	9 mg/shot
Bombardment medium	MS medium supplemented with 2 mg/l, 2,4-D (rice callus medium)
Callus placement in the petri plate	In the centre and in various concentric rings in 90 mm diameter petri plate
DNA concentration	1 mg/ml
Physical parameters:	
Helium pressure	450–1300 psi
Vacuum	26 mm Hg
Post-bombardment culture	On callus medium till GUS assay (48 h)

Table 2. Transient expression of GUS at various arrangements of rice callus at the time of bombardment with variable helium pressure

Helium pressure (psi)	Arrangement of callus in the petri plate	Transient expression of GUS*	Callus survival†
450	At the centre (distance between microcarrier and the target = 6 cm)	–	Good
650	At the centre (distance = 6 cm)	+	Good
900	At the centre (distance = 6 cm)	+++	Moderate
	At the centre (distance = 9 cm)	++	Good
	At the innermost concentric ring of the petri plate (distance = 6 cm)	++	Good
	At the innermost concentric ring of the petri plate (distance = 9 cm)	+	Good
1100	At the centre (distance = 6 cm)	++	Died
	At the centre (distance = 9 cm)	++	Moderate
	At the innermost concentric ring of the petri plate (distance = 6 cm)	++	Good
	At the innermost concentric ring of the petri plate (distance = 9 cm)	+	Good
1300	At the centre (distance = 9 cm)	–	Died‡

*Based on the distribution of blue spots on the callus; +, poor expression; ++, moderate expression; and +++, good expression of GUS; †Callus survival was observed in 15-day-old cultures; ‡Callus died within 48 h of culture.

Figure 1. Transient expression of GUS in bombarded callus of rice arranged in the centre of the plate with a distance of 6 cm and 900 psi helium pressure. Non-bombarded callus (a) and GUS expression in bombarded callus (b and c).

Figure 2. Arrangement of the callus at the innermost concentric ring of the plate on the platform for bombardment.

The target tissue (embryogenic callus) was arranged in concentric rings in sterile petridishes (90 mm diameter). The other physical parameters employed for the use of particle gun are summarized in Table 1. After the bombardment, the calli were cultured in dark for 48 h after which GUS staining was performed at 37°C as described by Jefferson¹².

Various parameters were employed for optimizing conditions for bombardment of rice callus to get transient GUS expression (Table 1). The lower helium pressures (450–600 psi) proved to be suboptimal while higher pressures (900 and 1100 psi) produced optimum results as evident in the form of blue spots on the callus following GUS histochemical assay (Figure 1; Table 2); GUS expression was not detected in control, non-bombarded callus (Figure 1 a). However, the highest helium pressure (1300 psi) led to the complete browning

of the callus (Table 2). Therefore, further optimizations were carried out using 900 and 1100 psi helium pressures.

Subsequently, the arrangement of the callus on the concentric rings of the plate was standardized (Table 2). First, the callus was placed at the centre followed by placing of the callus in the two innermost concentric rings. The maximum expression of GUS, concomitant with moderate survival of callus, was observed when the callus was placed at the centre or the innermost concentric ring of plate with a distance of 6 cm using 900 and 1100 psi helium pressure, respectively (Figure 1 b and c; Figure 2). However, better survival of the callus with moderate GUS expression was observed when the callus was placed at the centre or the innermost concentric ring of the petri plate on the platform at a distance of 9 and 6 cm using 900 and 1100 psi, respectively (Table 2). The latter parameters may be useful in recovering transgenics. These standardized bombardment conditions will be utilized for the development of fertile transgenic basmati rice harbouring agronomically-useful genes.

Impact of magnesium-aspartate hydrochloride on glucoregulatory system of two avian species

Madhusudan Das*, Santasri Sengupta and Bandana Guha

Histophysiology Laboratory, Department of Zoology, University of Calcutta, 35, Ballygunge Circular Road, Calcutta 700 019, India

*Present address: Gene Regulation Laboratory, Indian Institute of Chemical Biology, 4, Raja S.C. Mullick Road, Calcutta 700 032, India

Chronic administration of magnesium aspartate hydrochloride (Mg-Asp.HCl) induced hyperglycemia, hypoinsulinemia and hypercalcemia in common myna. But there were no changes in blood sugar and plasma insulin levels in the magnesium-fed pigeon. Plasma magnesium markedly increased in both the avian species, but plasma calcium level decreased significantly in pigeon, unlike common myna. Magnesium had no effect on pancreatic glutathione concentration in both pigeon and common myna. Concentration of magnesium and/or food habit may be the probable two factor(s) responsible for the different glycemic responses in pigeon and common myna.

THE interrelationship between magnesium and carbohydrate metabolism has regained considerable interest over the last few years. Insulin secretion requires magnesium. Magnesium deficiency results in impaired insulin secretion, while magnesium replacement restores insulin secretion. Experimental magnesium deficiency reduces the tissue sensitivity to insulin¹. Paolisso and Ravussin² reported that intracellular magnesium acts as a cofactor for numerous enzymes involved in carbohydrate metabolism. Despite the reports in mammals, except for chicken³, very little is known about the role of magnesium on the glucoregulatory mechanism of birds. In rats, depending upon the dose administered, magnesium-aspartate hydrochloride (Mg-Asp.HCl) exhibits Ca-antagonistic effect and inhibits the release of stress hormones^{4,5}. In chickens, changes in plasma level of magnesium have been reported to cause alterations of the rate of insulin release³.

The paper ascertains the role of Mg-Asp.HCl on gluco-regulatory mechanism with special reference to insulin release in two avian species belonging to different phylogenetic and nutritional status, and aims to establish, whether the response is related to the latter factor. Mg-Asp.HCl was used, since it is readily absorbed through the intestine⁵.

Adult specimens of pigeon (*Columba livia*) and common myna (*Acridotheres tristis*) were acclimatized to laboratory condition for a week. The animals were starved 18 h prior to experimentation, though water was provided *ad libitum*. Mg-Asp.HCl was orally adminis-

tered to pigeon (600 mg/bird/day) and common myna (300 mg/bird/day) in the morning at 10 a.m. for six consecutive days. On the 7th day, prior to autopsy, blood was withdrawn from the wing vein for biochemical assays. Birds were autopsied by cervical dislocation. The pancreatic tissues were dissected out and fixed in chrome-alum-Bouin's fixative⁶ for routine microtomy and 5 µm thick paraffin sections were stained using Eple's⁷ aldehyde fuchsin trichrome method. Using arsenomolybdate colour reagent, blood sugar was estimated by Nelson and Somogyi's method. Plasma insulin was measured by a direct radioimmunoassay with protocol and radiochemicals supplied by Board of Radiation and Isotope Technology, Mumbai, India. The radioactivity was measured in LKB-γ counter. Calcium was measured by using methylthymol blue method of Glindler and King and colour was measured in Perkin Elmer spectrophotometer (Model 550 S, USA). Magnesium was determined by the fluorometric method of Schachter and fluorescence was measured by Fluorescence Spectrophotometer (Hitachi, Model 650, Japan). Splenic lobe tissues of pancreas were collected and glutathione was estimated using spectrofluorometric method of Hissin and Hilf⁸. The statistical analysis was carried out by Student's *t*-test.

The islets of Langerhans are distributed more or less uniformly throughout the entire pancreas. Islets are composed of A, B and D cells. A cells are large with well marked outlines. The nuclei are round and oval with prominent nucleoli. The B cells consist of deep purple aldehyde fuchsin positive granules. The D cells are mostly spindle-shaped and are smaller than A and B cells. The D cell nuclei fill up the entire cell surface and possess light green positive cytoplasm. But no significant changes were observed in the islet cytology under light microscope after chronic treatment of oral Mg-Asp.HCl, both in pigeon and common myna.

A marked increase in blood sugar level and decrease in plasma insulin concentration were noticed in the magnesium-treated common myna. Blood sugar and plasma insulin levels remained unchanged in magnesium-fed pigeon. Plasma magnesium level significantly increased in both the experimental birds. Plasma calcium level significantly decreased in pigeon whereas in common myna its concentration showed a marked elevation. Pancreatic glutathione was not altered after treatment in both pigeon and common myna (Table 1).

An earlier report showed that disturbances in $\text{Ca}^{2+}/\text{Mg}^{2+}$ ratio alter the B cell responsiveness³. It is known in mammals that the intracellular calcium is essential for insulin release, while magnesium inhibits Ca^{2+} uptake⁵. Thus the increase or decrease of plasma calcium level is expected to increase or decrease the insulin release. In the present investigation, chronic treatment of Mg-Asp.HCl produced hyperglycemia, hypoinsulinemia and hypercalcemia in common myna. The

RESEARCH COMMUNICATIONS

Figures in parenthesis represent the number of birds.

earlier report had shown that both Ca^{2+} and Mg^{2+} ions compete for a common cationic carrier system located in the B cell plasma membrane⁹. Hence, in the common myna, magnesium probably inhibits glucose-induced calcium uptake and subsequent insulin release by the B cell. Similar findings are also reported in mammals¹⁰. Our finding is supported by the observation of Hazelwood¹¹ in chicken where absence of magnesium in the perfusate markedly increases insulin output. In contrast to common myna, pigeon exhibited no significant changes in blood sugar and plasma insulin levels after chronic treatment of magnesium. Plasma level also decreased significantly in pigeon as compared to common myna. Hence, our results indicate that pigeon deviates from common myna and chicken¹¹, in its glucoregulatory mechanism after chronic treatment with magnesium. Classen *et al.*¹² pointed out that concentration of Mg-Asp.HCl is very important in exhibiting its Ca-antagonistic action. Thus, it is quite possible that the magnesium concentration was not optimum to cause Ca-antagonistic action and in turn failed to alter insulin release in pigeon, unlike in common myna. The differential findings between the two avian species could be due to the different nutritional status of pigeon and common myna which support the earlier work of Bentley¹³. Furthermore, increased level of plasma magnesium has no effect on pancreatic glutathione content in the two avian species studied.

BOOK REVIEWS

Stereochemistry and Mechanism through Solved Problems. P. S. Kalsi. New Age International Publishers, 4835/24, Ansari Road, Darya Ganj, New Delhi 110 002. 1994. x + 373 pp. Price: Rs 165.

The book deals with the topics stereochemistry and reaction mechanism through problems and solutions. The purpose of the book as suggested by the author in the preface, is to train students for appearing in post-graduate university examinations as well as competitive examinations like joint UGC-CSIR eligibility test. The book therefore, serves as a model question-answer book for strategic learning.

Both the areas of application and strategic learning are most sought-after materials for the benefit of the students. The book is useful to teachers for selecting problems for discussion in the classroom, setting questions for formal and terminal tests. The purpose of the book is to train students in application of the knowledge and understanding they have in stereochemistry and reaction mechanism. Problem solving builds up the application aspect of learning. The book presents each subtopic through posing a problem and solving it. Therefore, this book provides a very good medium for self-learning the application of knowledge in the area of stereochemistry and reaction mechanism.

The book contains eleven chapters. Each chapter begins with enlisting salient features of subtopic, followed by problems and solutions in the form of model answers, gradually covering the entire subtopic. The book is full of nice illustrations which depict three-dimensional aspects of the molecular structures. Chapter 4 develops the fundamental concept of molecular symmetry and chirality which is very helpful in learning stereochemistry.

Chapter 6 deals with Optical Rotatory Dispersion as an instrumental method for determining configuration of some molecules. Problem 1.60 of Chapter 1 also discusses use of NMR in identifying certain conformers. However, a separate chapter discussing principles of instrumental methods and their application to identify stereoisomers and to determine three-dimensional molecular structures would

have been useful to readers.

It will be beneficial to the readers if aliphatic electrophilic substitution reaction (SE1, SE2, and SEi) and the effect of substrate, leaving group and solvent can be explained with examples in a separate chapter. Again, if the reaction intermediates, i.e. carbonium ions (classical and non-classical), carbanions, carbenes, nitrenes and arynes are discussed elaborately with examples, it will be helpful to the students appearing at various competitive examinations.

The book needs minor corrections at some places.

Some questions do not contain proper action verbs. For example: Problem 1.5 (page 5) states 'Draw and explain the hybridizations...', which can be modified more appropriately as 'Explain the hybridization... with suitable diagrams'. Problem 1.23 (page 16) stating: 'What do you understand by gauche and anti-conformations' may be modified as 'Define gauche and anti-conformations'. Problem 4.13 b (page 139) stating 'Tell, if *trans*-1,2-dichloro cyclopropane is asymmetric or dissymmetric?' can be modified as 'State whether *trans*-1,2-dichlorocyclopropane is asymmetric or dissymmetric'.

Some answers are not explicit, some are with mistakes. For example, in problem 1.85 (page 48) numbering of carbons in cubane would have made it easy for a reader to correlate the nomenclature. In problem 2.71, the answer states the condition for a compound to be meso isomer whereas the question was to identify a meso isomer in a list of three compounds. In problem 2.72, the answer does not explain why only three isomers are observed when there is a possibility of four isomers. Besides, the diagram of *cis*-1,3 dimethylcyclohexane would have made the answer complete. In Chapter 10, Huckel and Mobius systems should have been explained with diagram showing nodes.

In problem 1.25 and many others, the answer is in the conversational style. The book aims at giving model answers for written tests. So the answer should not be a phrase or an incomplete sentence.

The order of some problems needs change. For example, answers to problems 8.6b and 8.6c are referred to Chapter 9 (9.33a and 9.33b). The ques-

tion of stereo and regio selectivity should not have been raised in Chapter 8 when it is discussed in Chapter 9.

As a whole the book is very useful to both teachers and students for classroom and test purposes.

State of the Art in Polymer Science and Engineering in India. M. Santappa. T. R. Publications Pvt. Ltd., PMG Complex, 2nd Floor, 57, South Usman Road, T-nagar, Chennai 600 017. 576 pp. Price: Rs 795.00

In this book the author has compiled the summary (often in one line) of the research papers on polymers published by Indian scientists, technologists and engineers based on their research work carried out in India for the last fifty years or so. He has set aside biopolymers excepting collagen from the purview of his compilation and also the polymer involved works in the fields of electronics, material science and space science. The author has, by and large, refrained from making commentary on the works and accordingly the book turns out to be a reference book on the subject and not a review. In the preface of the book he has commented that although our contributions to the polymer literature are substantial in quantity, they are poor in quality with very few exceptions, of course. Our works are mostly repetitive, uninteresting and often devoid of a clear objective. The question therefore arises - Why then did the author undertake such an arduous task to compile such voluminous but insignificant contributions? The author answers that the book has laid bare the glaring deficiency in the quality of our research papers. It comes as a lesson for the posterity so that quality gets priority over quantity.

The author is one of the seniormost and a much respected member of the profession. So his comments command attention and respect. But is the scenario not the same for every other field of research in our country? That this is

so is common knowledge. In order to find the cause behind the generally dismal performance in scientific research, one has to look into the socio-economic conditions of the country. We are amongst the poorest nations of the world with an average per capita income of around 300 dollars and a literacy rate of only about 50%. With such abysmally low economic condition and literacy it is hard to expect that our science will flourish and the general level will compare with the best in the world. It may be possible to build certain centers of excellence with excessive funding for the sake of improving the quality of research. But this would not help improve the general level, as our experience during the last two decades of effort in this respect would prove.

It may be pertinent here to discuss the situation in the two so-called Asian tiger countries, viz. South Korea and Taiwan. There were hardly any publications coming out from these countries even 20 years ago. Now, they are economically sound and scientific research there has gained ground so much that our scientists are flocking to these countries to gain post-doctoral research experience. Paradoxically, according to the *Economist* (Economist Newspaper Limited, London, 1996 reproduced in the *Sunday Statesman*, Calcutta, 22 September, 1996) one of the key factors contributing to the great economic boom in these countries has been identified to be their emphasis in imparting primary as well as secondary-level education to the whole population rather than to a part of it which would otherwise have assumed elitist character. The university education and research gained importance in a subsequent stage. The example of these two countries which belonged to the third world three decades ago proved right the prophecy of Carl Sagan, the renowned astrophysicist, who holds the view that Science in the third world countries is not gaining ground because of the lopsided educational policy which is elitist in character. We are yet to learn from the above examples.

Coming back to the book proper, the author has done a stupendous job in going through so many papers, which amount to more than one thousand. He has classified the work into eight top-

ics, covered in as many chapters. These are; 1. Synthesis of novel monomers, catalysts and polymers 2. Kinetics of polymerization; 3. Graft copolymerization; 4. Physical chemistry of polymers; 5. Chemical engineering and technology of polymers; 6. Some properties and uses of polymers; 7. Applications of polymers in industries; 8. Science & Technology of leather. The last one surely has found place because of the association of the author with the Central Leather Research Institute as its Director. The contributions in each of the above topics have been entered institutionwise, i.e. Universities, Research institutes, CSIR laboratories, IITs, other technological Institutes, Defence Research Laboratories, Space and atomic research laboratories. Also as has been stated earlier, the author has not made any commentary on the works except on rare occasions. Accordingly, the book is not a review but a dictionary of polymer research done in India during approximately the last 50 years.

It may be noted that the bulk of polymer research in India consisted of studies on free radical polymerization, finding out new initiator systems and establishing the kinetics and mechanism of polymerization reactions. In many other countries, polymer research started in much the same way. But while they quickly caught up with the ever-emerging new lines of research, we in India continued in the same line far too long. One obvious reason is that this particular line of research required minimum of funding. At present, however, in some of our laboratories research is going on in contemporary topics but these are very few in number. Unfortunately, on going through the book one does not easily get a feel of this change.

Furthermore, even though the stated policy of the author is not to evaluate the merit of the works, it would have been proper to highlight the landmark achievements which are not many in number and discuss them in brief. Take for example, the dye techniques developed by Palit in the early sixties. This technique stands out as the most original work from India in the sixties. It provided the polymer chemists with an easy and inexpensive means of identifying transient free radical intermediates which are used to initiate free radi-

cal polymerization. The technique served as a substitute of the hazardous radio-chemical assay technique. Using this, Palit and coworkers unraveled the mechanism of a large number of redox reactions that generate free radicals. Although mention has been made of this technique on pages 71 and 139, the significance and importance of the technique have not been properly made out and a brief description of the principle of the technique would have been desirable. This is particularly so since the author has in many places of the book devoted space to describe non-seminal works. The result is that many a gem got lost in the milieu.

As regards the preparation of the book, the compilation is disjointed in many places. Consider, for example, the two sentences under section 6 on page 139. The first sentence speaks of Palit's dye technique while the immediately next one deals with an entirely different subject. Also wrong references are cited for several works. For example, on page 70, 3rd para, refs. of Maiti *et al.* and Kar *et al.* are wrongly placed, similar is the situation with Das *et al.* in para 4 and also the references 147-151 in the same para are inappropriate. Furthermore, some references are also factually wrong, e.g. 166 and 167 on page 92. In chapter 1 there is no mention of the contribution from Indian Association for the Cultivation of Science in the contents and this contribution has been included under that of Calcutta University on page 27, section 10. There is also no uniformity maintained in the reference list. On the surface these lapses do not appear to be grave enough but such errors do not befit a reference book.

Finally, the title of the book *State of the Art* seems a misnomer. Perhaps, an appropriate title would have been 'A Concise Account of Research of Polymer Science and Engineering done in India' or something similar. Nevertheless, the book will serve the purpose of a source book on the subject and like all books of reference it should find place in technical and science libraries.

A pioneer in X-ray crystallography, electron microscopy and biophysics

An obituary of R.W.G. Wyckoff (1897–1995)

Ralph Walter Graystone Wyckoff, one of the most remarkable American men of science, died at the age of 97 in 1995. A study of his life gives us some glimpses into the early history and developments of X-ray crystallography, electron microscopy and biophysics in USA.

Wyckoff's forebears came from Holland and settled in 1634 in the city of New Amsterdam which is now called New York. His father was a buildings contractor and Ralph was the first scientist in his family. Even when in school, he published papers in the *Journal of the American Chemical Society* and also took some patents. As a graduate student in Cornell University he made a serious but unsuccessful attempt to discover the missing element eka caesium from *pellucite*, a caesium containing mineral. This element, a short-lived radioactive one, was later discovered by Mlle Peres, one of Madam Curie's collaborators. While searching for a new problem for his doctoral thesis, Wyckoff came to know that in Cornell there were two visiting Japanese scientists – Nishikawa and Asahara. Shoji Nishikawa was a student of the famous Tarahiko Tarada (1878–1935) who discovered 'Bragg's' law independently of Bragg. As early as 1913 Nishikawa discovered X-ray fiber diffraction patterns of textile materials and of asbestos and did the structure of spinel. He was the first to realize the importance of the theory of space groups as a general and logical means for X-ray analysis.

Wyckoff, under the direction of Nishikawa, solved the structure of caesium dichloriodide and sodium nitrite which were amongst the earliest structures to be solved in USA using single crystal diffraction. He used Laue photography – but soon shifted over to photographing Bragg reflections. After his doctorate and immediately after the end of the war, Wyckoff went to the Geophysical Laboratory, Washington where he set up an X-ray group to determine inorganic and minerals structures. In 1922 he published the famous tome – *The Analytical Expression of the Results of Space Groups as Applicable to the Calculation of the Structure Fac-*

tors. This book went into several editions and was responsible to a large extent in the spurt of the activity in X-ray crystal structure analysis. About the same time, many others including Kathleen Lonsdale in England and Hermann Mauguin in France derived similar expressions. These, together with those of Wyckoff were all incorporated in the International Tables published by the International Union of Crystallography.

When the physical chemist Noyes went from MIT to the California Institute of Technology (Caltech), he was intent on starting X-ray crystallography as he felt that determining the positions of atoms in a crystal would be very im-

portant to chemistry. Ellis, who was to be in charge of X-ray crystallography development in Caltech came to Wyckoff's laboratory to familiarize himself with the subject. Wyckoff himself also went to Caltech to help set up the X-ray laboratory under Dickinson – with whom Linus Pauling was to work and create a major revolution in the field of X-ray crystallography, inorganic and mineral structures.

In 1927 Wyckoff went to the Rockefeller Institute for Medical Research in New York and started a new laboratory to investigate organic structures. Robert Corey trained in Wyckoff's laboratory on organic crystals, solved the structure of urea there and then moved over to Caltech and became known for his work on amino acids, etc.

Wyckoff's interest in crystals of biological interest was fostered by his close associations with P. Lecomte du Nouy, one of the pioneers of biophysics

and with Alexis Carrel whose development of tissue culture made it one of the fundamental techniques of modern biology.

Wyckoff (and his collaborators) attempted to crystallize proteins to obtain their X-ray diffraction patterns. He felt that the ultra centrifuge could be used for purifying proteins. As a first step to preparing good crystals, he went on to design and construct comparatively large ultra centrifuges with airturbines. In his design he substituted the steels normally used in such instruments by light and strong aluminum-magnesium structural alloys developed by Dow Chemicals. He used these centrifuges for purification of plant and animal proteins and viruses and obtained extremely beautiful protein crystals including that of haemoglobin. Unfortunately he did not succeed in getting X-ray diffraction patterns (probably because he did not keep the crystals in their mother liquor during photography as Bernal and Hodgkin did later).

He then went on to newer applied fields. Equine encephalomyelitis virus was the first of the viruses to be purified by this method. Wyckoff and J.W. Beard made an effective formaline-killed vaccine from these purified preparations. In view of the serious encephalomyelitis epidemic among horses in the United States, Wyckoff was invited to work in the Lederle Laboratories, where he developed, tested and produced several million doses of this vaccine. Following their massive use, the epidemic ceased and there was no major recurrence of the disease in USA. Wyckoff's laboratory then turned to the production of vaccine for typhus fever which was then raging. Large quantities of vaccine were made for the use of the US army. In response to the need for human blood plasma for treatment of war wounds in the Second World War, Wyckoff and his group next developed the process and built large-scale freeze drying plants for plasma with which they produced 2000 plasma packages per day.

After this very successful detour into applied and useful biophysics, Wyckoff returned to the life of fundamental research in the University of Michigan.

Because of his manual dexterity, he was able to repair an old and unusable electron microscope and in this process he suggested so many improvements that he was appointed consultant to RCA, USA and Phillips, Holland. During his electron microscopy researches, Wyckoff had difficulty in estimating the size and height of virus particles. At that time he met Robley Williams, a Caltech astronomer who was coating some mirrors in the Dept of Physics and Astronomy in Michigan. Williams said that it was standard practice to get the height of lunar mountains by knowing the angle at which the sunlight falls on them and measuring the length of the shadows they cast. The solution was to make the viruses cast shadows by evaporating gold from one side and leaving a shadow on the far side. The technique of metal shadowing, so familiar to electron microscopists now, was one of the major contributions of Wyckoff and his group to electron microscopy.

For the first time the shadowed virus particle revealed its true three-dimensional shape and photographs of particles of several viruses were taken. A particularly satisfactory development that followed was the direct demonstration of the ordered arrangement of molecules within 'virus crystals'. So impressed was J. D. Bernal with these photographs and developments that he invited Wyckoff to an international meeting he was convening in London. The participants were amazed at the simplicity and effectiveness of the technique. It was after this meeting that shadowing became a universal tool in the hands of electron microscopists.

It was also after this International meeting that the early confabulations took place between W. L. Bragg, P. P. Ewald, J. M. Bijvoet, R. W. G. Wyckoff and many others about the starting of the International Union of Crystallography and the International Union of Electron Microscopy. The former was established in 1948 with W. L. Bragg as its first President, J. M. Bijvoet its second (1951) and R. W. G. Wyckoff its third (1954). The International Union of Electron Microscopy was formed much later. When Wyckoff was at the Rockefeller Centre, he had started looking at collagen and later did much work on the electronmicroscopy of collagen

in the National Institute of Health and other institutions in Washington where he went from Michigan. His old friend Nishikawa sent one of his students H. Noda to work with him. Noda went back to Japan and became one of the authorities on collagen and its fine structure.

After retirement, Wyckoff joined the University of Arizona and set up a laboratory for the study of the fine structure of biological solids. Here he extended his interest in collagen to other proteins. He was amongst the first to find collagen in fossilized bones of the animals of Pleistocene era. His laboratory went on to study older fossils and dinosaur bones. He also used paper and liquid chromatography for the analysis of the amino acids extracted from these bones. Using electron microscopy he studied the structures of proteins in fossilized bones and proved beyond any doubt that collagen can persist over the geologically significant periods of time. His laboratory also analysed the ancient proteins, especially collagen, to see how they differ from the present day ones and whether these differences are due to chemical and/or biological evolution.

One of Wyckoff's life-long projects was the unified description of the results of crystal structure analysis. This resulted in the publication of his first group of volumes on the crystal structures (4 sections and 5 supplements, 1948-1960) and his later *Crystal Structures* (5 volumes, 1963-1967). He had put in an enormous effort into this but as it has been said 'his effort was much less and that he saved for thousands of crystallographers later'.

Wyckoff was recipient of many honours. He was elected to the National Academy of Sciences, The American Academy of Arts and Sciences and foreign member of the Royal Society, London and Royal Academy of Netherlands and a corresponding member to the Academie des Sciences, Paris. He was very proud of his election as Honorary Fellow of the Indian Academy of Sciences (1955). Almost every country in the world honoured him for his work on X-ray crystallography and electron microscopy. The American nation was grateful to him for his production of life-saving vaccines for which he was awarded many prizes.

I met R. W. G. Wyckoff in Washington in the spring of 1955. I first congratulated him on his election as President of IUCr. He said he cherished his election as Honorary Fellow of the Indian Academy of Sciences more. The reason he gave was that his attachment and ambitions in crystallography were not as much as his admiration for Indian philosophy, especially that of Ramakrishna Paramahansa and Swami Vivekananda.

Wyckoff knew C. V. Raman well ('highly original guy and a bit too energetic'). They had met first in 1924 when Raman had gone to Caltech as a visiting professor and again later in 1948 in Boston. Raman had bought for his personal library all of Wyckoff's books immediately after they were published, e.g. *Structure Factors* in 1922 and *Crystal Structures* in 1924. Wyckoff happened to be the examiner of my D Sc thesis. He was not at all happy that I had not accepted the fellowship he had offered me to work with him in electron microscopy. ('You missed a lot as you were not there to participate in the exciting things that were happening'). I remarked about his work on the dispersion corrections in anomalous scattering and on the later epoch-making discovery of Nishikawa and Matsukawa of the failure of the Friedel's Law under anomalous scattering conditions, on both of which some of my X-ray work was based. He talked most affectionately about Nishikawa and his association and life-long relationship with him. After the second world war Wyckoff resumed close contacts with him which were unbroken till Nishikawa's death in 1952. 'I am eternally grateful to him for introducing me to Japanese culture, Japanese art and to the eastern philosophies.'

Wyckoff did much for the growth of X-ray crystallography internationally and in USA. To quote from one of the articles in *The 50 years of X-ray Diffraction* edited by P. P. Ewald - 'The meeting of Ralph Wyckoff with the shy and gentle Nishikawa in 1917 may be said to have an implicit significance to the growth of X-ray crystallography in USA'.

DEPARTMENT OF SCIENCE & TECHNOLOGY

Programme on Nonlinear Phenomena, Complex Matter and Biologically Inspired Physics

The importance of nonlinear science, soft condensed matter (such as colloids, powders, polymers and membranes) and biologically inspired physics has emerged very clearly in recent years. In view of this and given the large mutual overlaps of these disciplines as well as their interdisciplinary nature, the DST has considered it fit to constitute a separate Programme Advisory Committee (PAC) specifically to foster research in these areas. Suitable project proposals are invited in the above general fields.

Research proposals should pay particular attention to the development and application of ideas and techniques that cut across disciplines and/or seek to elucidate and provide insight into the general paradigms of complexity and nonlinearity.

Proposals that come under this general purview include:

Dynamical phenomena far from equilibrium, driven systems, chaos, especially spatiotemporal. This encompasses both model systems such as sandpiles and driven lattice gases as well as 'real' examples such as colloids in shear flow and sedimentation, turbulence, kinetics of phase ordering, granular matter (powders), earthquakes, pattern formation, etc.

Physics of soft condensed matter. Membranes (biological and model), Langmuir monolayers and Langmuir-Blodgett films, micelles, vesicles, lamellar structures, microemulsions, emulsions, foams, and other structures in surfactant solutions: liquid crystals, both thermotropic and lyotropic, polymer solutions, gels, and melts: colloidal suspensions, including ferrofluids, electro-rheological fluids, etc.

Biologically inspired physics. Models in evolutionary biology and population genetics, evolution of complexity, neural networks, optimization, protein folding, motor proteins and molecular ratchets, etc.

Qualified researchers interested in submitting project proposals to be considered for funding may write to the following address for further details:

DEPARTMENT OF BIOTECHNOLOGY

AWARD OF BIOTECHNOLOGY OVERSEAS ASSOCIATESHIP: 1996-97

Applications are invited from Indian Nationals for the award of Biotechnology Overseas Associateships (1996-97) for conducting advanced research or undergoing specialized research training in overseas research institutes/laboratories in the priority areas of biotechnology, viz. (i) Basic molecular biology; (ii) Microbial genetics; (iii) Recombinant DNA technology; (iv) Molecular immunology, immunogenetics and immunodiagnostics; (v) Molecular virology; (vi) Animal tissue culture, human hybridomas and cell-culture-based vaccines; (vii) Plant tissue-culture; (viii) Genetic disorders and gene therapy; (ix) Animal biotechnology; (x) Aquaculture and marine biotechnology; (xi) Peptide and nucleic acid chemistry and applications; (xii) Protein and enzyme engineering; (xiii) Modern techniques in industrial microbiology and bio-conversion; (xiv) Biochemical engineering, bio-separation, process optimization and computer modelling; (xv) Bio-informatics; (xvi) Emerging areas.

The applicants should possess a Ph D/M D degree in the area related to biotechnology, with a good record of research contributions in biotechnology. The candidates should hold a regular/permanent position in research institutions/universities and should be actively engaged in biotechnological R&D work. Applications from persons working on temporary positions such as research fellows or associates will not be considered.

Details of the Award

1) Two categories of Associateships, namely Long-term and Short-term associateships are awarded. 2) The Long-term Associateship is awarded for a period of one year only and it is not extendable. The Short-term Associateship is normally awarded for three months only. However, the Short-term Associateship may be awarded for a maximum period up to six months in cases where a longer duration is necessary and justified. Such proposals will be considered by the Department purely on the merit of the case and the decision of the Department will be final. 3) The Long-term Associates are entitled to (a) Monthly Associateship @ US \$1500 or its equivalent in the country of study; (b) Personal Equipment Grant of Rs 4000 (one time grant); (c) Cost of air passage in economy class by Air India for joining overseas laboratory and back; 4) The Short-term Associates are entitled to (a) Monthly Associateship @ US \$1800 or its equivalent in the country of study; (b) Cost of air passage for joining overseas laboratory and back. 5) The selected candidates may receive the payment of salary and continuance of other service benefits by the institutions to which they belong. However, no liability on any of this account will be borne by DBT; 6) Selected candidates shall be required to execute a Service Bond to serve in India for a period of 1 to 3 years depending upon the duration/category of the Associateship awarded after return to India. Candidates should submit their applications typed on plain paper (one copy) complete with enclosures in the format given below *Through Proper Channel* to the Sr. Scientific Officer-I (Attention: Mrs. Suchita Ninawe), Department of Biotechnology, Block-II, 6th Floor, CGO Complex, Lodhi Road, New Delhi 110 003 on or before *15th January 1997*.

Age Limit

- (a) Long-term Associateship: not exceeding 40 years.
- (b) Short-term Associateship: not exceeding 50 years.

Candidates *should not have crossed* the above prescribed age limit as on 15th January 1997, the last date for receipt of application. The above prescribed age limits will not be relaxed.

FORMAT

Application for the Biotechnology Overseas Associateship 1996-97

1) Category of the Associateship Applied for (Long-term or Short-term); 2) *In the case of Short-term Associateship only*, (a) Duration of the Associateship applied for, (b) Justification (in case the proposed duration exceeds three months); 3) Applicant's name (in full), designation and address; 4) Father's/husband's name (in full); 5) Date, place of birth and age (as on 15th January 1997); 6) Academic qualifications (degree onwards with year, name of the institution, subjects of specialization and distinctions, if any); 7) Details of the nature and duration of the present and past employment; 8) Particulars of current research work (not exceeding one page); 9) Research publications in indexed journals during the last five years (enclose a list; exclude presentations in seminars/symposia; attach reprints of 3 research papers which you consider the best); 10) Details of the proposed subject of research/training and its relevance to the priority areas identified by DBT and the plans and programmes of the parent institute (the proposal should be concise, the objectives should be clearly stated and it should not exceed 2 pages); 11) Proposed place of research/training (indicate whether the consent of host institutions has been obtained); 12) Details of past overseas visits (mention the country visited, purpose, year and duration); 13) Have you been previously selected for any Associateship award (National/Overseas) of DBT? If so, give details; 14) Particulars of R&D projects sanctioned by DBT (ongoing/completed), if any; 15) Priority area of the proposed research/training.

Place

Date

Signature of the Candidate

Statement from the Present Employer

As per the terms and conditions of the Associateship, the candidates selected for the awards should be granted deputation terms like payment of salary and continuation of other service benefits during the Associateship by the employers. The employer's statement should contain a certificate to this effect as also about continuity of employment after the Associateship period. Applications which are forwarded without the employer's statement may not be considered.

NOTE: 1) The candidates should correspond themselves with their proposed host institution abroad for placement; 2) Only applications sponsored by the employer and forwarded by the head of the institution/organization shall be considered for selection for the award of the Associateships. The applicants are therefore, advised to ensure that their applications *Through Proper Channel* should reach the Department on or before the closing date; 3) All the applicants will be informed about the result of selection in due course and therefore, no interim queries in this regard will be attended to.
